**Lecture – 14**  
**Interpolation Methods - 1**

Hello and welcome to today's lecture. Last 2 sessions we had on practicals. That is we compiled several programs and executed them. Now we will receive our discussion on numerical methods and describe methods for interpolation today. So before I start interpolation, let us again summarize what our numerical methods are there. Now you see that we were discussing numerical methods.

**(Refer Slide Time: 00:43)**

And what do these numerical methods involve? Analysis of errors in arithmetic operations, interpolation, curve fitting, matrix methods, integration and differential equations, transforms, use of random numbers, use Scilab and applications of special relevance. This is what numerical methods are.

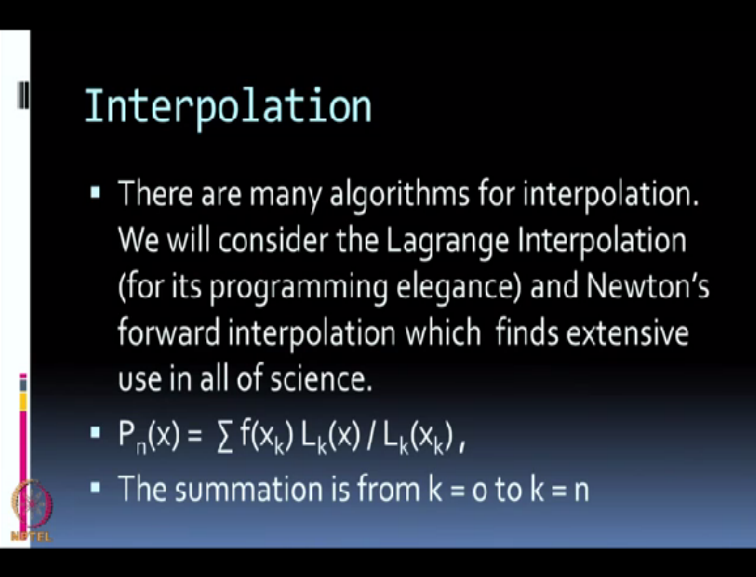

**(Refer Slide Time: 01:04)**

and  $f(x)$ .

We want a function to pass through those points and at points in between that, that is in the range between  $x_0$  and  $x_1$ ,  $x_1$  and  $x_2$ , these are points intermediate between the points on the  $x$  axis. For those intermediate points, we want values of  $f(x)$ . So experiment or my data does not have those values of  $f(x)$  for intermediate values. The interpolating curve gives me the values at those intermediate points, okay.

**(Refer Slide Time: 02:41)**

The slide has a black background with white text. The title 'Interpolation' is at the top in a light blue font. Below it is a bulleted list. The first bullet point discusses algorithms for interpolation, mentioning Lagrange and Newton's methods. The second bullet point is a mathematical formula for the Lagrange interpolation polynomial. The third bullet point states the range of the summation index  $k$ .

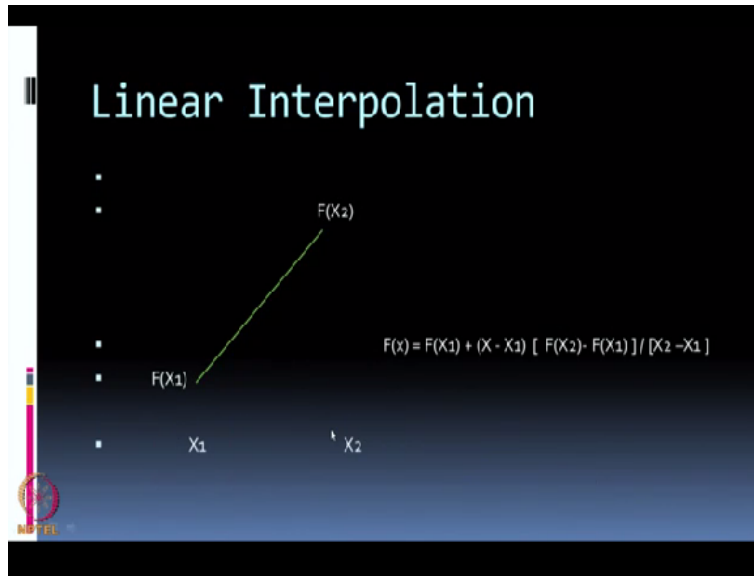

## Interpolation

- There are many algorithms for interpolation. We will consider the Lagrange Interpolation (for its programming elegance) and Newton's forward interpolation which finds extensive use in all of science.
- $P_n(x) = \sum f(x_k) L_k(x) / L_k(x_k)$ ,
- The summation is from  $k = 0$  to  $k = n$

So we will consider 2 methods of interpolation. There are several methods. One is LaGrange interpolation. One is a Newton's interpolation. But Newton's interpolation finds extensive use in many many applications. So we will do the program for Newton's interpolation first and we will also consider LaGrange interpolation. So what does LaGrange interpolation involve? Is that the  $n$ th order polynomial, this  $P_n(x)$ ,  $n$  refers to the order of the polynomial.

The  $n$ th order polynomial is given in terms of  $f(x_k)$  which are the values of the function at known points  $k$ . So normally we take  $k$  to go from 0 to  $n$ . So 0 to  $n$  means if there are, if  $n$  is 10, 0 to  $n$  would be 11. So those 11 values of  $f(x_k)$ ,  $L_k(x)$  evaluated at those 11 points,  $L_k(x)$  evaluated at each one of the values of  $k$ ,  $L_k(x_k)$ . So the formula is given in the later slide. So before I proceed, I want to define what is a linear interpolation?

**(Refer Slide Time: 03:47)**

This particular slide demonstrates what is linear interpolation.  $x_1$  and  $x_2$  are the points on the x axis and this line is a line that has values  $fx_1$  at  $x=x_1$  and  $fx_2$  at  $x=x_2$ . So between these 2 points, I do not have any data. And I want to interpolate using a straight line that is for all values between  $x_1$  and  $x_2$ , I want to say that the function is a straight line and I want values of  $fx$  at those points.

So how do I get the values at those points? You know that the equation of a straight line is  $y=mx+C$ . So  $m$  is the slope, okay;  $C$  is the intercept and  $y$  is my function,  $y=mx+C$ . So how do I write the interpolating polynomial here?  $fx$  which is the value of the function at any point between  $x_1$  and  $x_2$ . That  $fx$  is  $fx_1$  which is the starting value of the function,  $fx_1$ , +the slope of this.

What is the slope of this  $fx_2-fx_1/x_2-x_1$ , that is my slope,  $fx_2-fx_1/x_2-x_1$ . This is the slope, times  $x-x_1$ . So when I do this, when  $x=x_1$ , you know that this term is 0, then  $fx=fx_1$ , that is my starting point. When  $x=x_2$ , this  $x_2-x_1$ , there is a denominator  $x_2-x_1$ , both of them cancel. All that remains is  $fx_2-fx_1$ .  $fx_1$  cancels with this  $fx_1$ . Function becomes  $fx_2$ . When  $x=x_2$ , the function is  $fx_2$ .

When  $x=x_1$ , the function is  $fx_1$ . At all intermediate points, my function is defined through this formula. Now this particular function will work well beyond  $x_2$  also. Suppose I extend this line

beyond, that function will work very well beyond this as well as below  $x_1$ . Because a line extends all the way on the right side as well as all the way on the lower side. The straight line will extend and this function will give me values of the function at all points for all values of  $x$ .

But it may so happen that beyond  $x_2$  and below  $x_1$ , it may not be a straight line. So straight line is not a good method for interpolation if  $x_1$  and  $x_2$  are far apart. If  $x_1$  and  $x_2$  are very near, straight line interpolation is very good. So now suppose I have more than 2 points, what is a good polynomial that I can fit that is what I am going to describe next, okay.

**(Refer Slide Time: 06:33)**

**Lagrange's polynomials**

- $L_k(x) = (x - x_0)(x - x_1) \dots (x - x_{k-1})(x - x_{k+1}) \dots (x - x_n)$
- 
- $L_k(x_k) = (x_k - x_0)(x_k - x_1) \dots (x_k - x_{k-1})(x_k - x_{k+1}) \dots (x_k - x_n)$
- 

We will discuss how to programme this in a practical session. You may attempt this yourself.

So remember LaGrange interpolation is a LaGrange polynomial. I already said in the last slide. Let us go back. It is  $f(x) \cdot L_k(x) / L_k(x_k)$ . I am just going to define  $L_k(x)$  and  $L_k(x_k)$ , okay. So what is  $L_k(x)$ ?  $L_k(x)$  is  $(x - x_0) \cdot (x - x_1) \cdot \dots \cdot (x - x_{k-1}) \cdot (x - x_{k+1}) \cdot \dots \cdot (x - x_n)$ , only the  $k$ th term is not there. That is  $(x - x_k)$  is not here. Because I want  $L_k(x)$ ,  $(x - x_k)$  is not there.  $(x - x_{k+1})$  up to  $(x - x_n)$ . All the products are there. There are  $n$  products except  $(x - x_k)$ .

So that is my, this is the polynomial. This is a polynomial of the  $n$ th order because there are  $n$  terms. What are those  $n$  terms?  $n, n-1, n-2, k-1, k+1$ .  $k$  is not there up to  $(x - x_0)$ . This is a polynomial of order  $n$ . Then  $L_k(x_k)$  is a factor where in place of  $x$ , I have  $x_k$ , okay. So what is  $L_k(x_k)$ ?  $(x_k - x_0), (x_k - x_1), (x_k - x_{k-1}), (x_k - x_{k+1}), \dots, (x_k - x_n)$ , just as here.  $(x_k - x_k)$  is not there because  $(x_k - x_k)$  will be 0. So that is not there.

$x_k - x_{k+1}$  up to  $x_k - x_n$ . So this is,  $L_k x$  is a polynomial.  $L_k x_k$  is just a term. So my polynomial is  $f(x_k) * L_k x / L_k x_k$ . We will discuss this program a little later today. You may also try to program it yourself before looking at our solution. Because it is only when you attempt, you are on programs, you will get a better mastery, okay. So now this is my LaGrange polynomial.

**(Refer Slide Time: 08:26)**

The slide is titled "Newton's Interpolation" in a light blue font. It contains a bulleted list of three items. The first item states that given four points  $f(x_0), f(x_1), f(x_2), f(x_3)$ , we want to calculate a third-degree polynomial. The second item shows the formula  $P_3(x) = c_0 + c_1(x-x_0) + c_2(x-x_0)(x-x_1) + c_3(x-x_0)(x-x_1)(x-x_2)$ . The third item is a small square bullet point. The slide has a dark blue background with a vertical bar on the left side containing a small logo.

The next one I want to consider is a Newton's interpolation. This is slightly different from LaGrange interpolation. So the formula is a lot simpler. Now I want to consider a third degree polynomial. What is a third degree polynomial?  $x$  occurs to the third power. So in my problem, 4 values of  $x$  are given,  $x_0, x_1, x_2, x_3$ . 4 values of  $x$  are given and 4 values of the functions are given,  $f(x_0), f(x_1), f(x_2), f(x_3)$ .

Now I want a polynomial in the range  $x_0$  to  $x_3$ . So whenever you find a function between  $x_0$  and  $x_3$ , it is called interpolation. Whenever you want a value below  $x_0$  and beyond  $x_3$ , it is called extrapolation. We are not too keen on extrapolation because extrapolation has far too many errors compared to interpolation and we have no knowledge of the function beyond  $x_3$  and no knowledge of the function less than  $x_0$ .

So we will not worry about extrapolation. It is just interpolation. The polynomial, Newton's polynomial is given by  $P_3(x) = c_0 + c_1(x-x_0) + c_2(x-x_0)(x-x_1) + c_3(x-x_0)(x-x_1)(x-x_2)$ , we want to determine this constant,  $+C_1 * x - x_0 + C_2 * x - x_0 * x -$

$x^3 + C_3x^2 + C_2x + C_1$ . So there are 4 terms here. The first term is a constant. Second term is a linear term,  $x - x_0$ . The third term is a quadratic term because  $x^2$  will appear here. And the last one is a cubic term,  $x^3$  will appear here.

So this is an interpolating polynomial for these 4 points. Whenever you have 4 points, you get a third order polynomial. Whenever you have 2 points, you get a straight line. Whenever you have 3 points, you get a parabola. So I would want you to work how to get a parabola given  $x_0, x_1, x_2$  and  $f(x_0), f(x_1), f(x_2)$ . I will leave that as an exercise. Now we want to program for this  $P_3(x)$ , so we want to determine the formulae for  $C_0, C_1, C_2$  and  $C_3$ . That is the whole strategy in Newton's interpolating polynomial. So now let us look at the formula.

**(Refer Slide Time: 10:41)**

**Newton's Interpolation**

- $c_0 = f(x_0)$
- $c_1 = \Delta^{(1)}f(x_0, x_1) / (x_1 - x_0) = [f(x_1) - f(x_0)] / (x_1 - x_0)$
- $c_2 = \Delta^{(2)}f(x_0, x_1, x_2) / ((x_2 - x_0)(x_1 - x_0))$   
 $= [\Delta^{(1)}f(x_1, x_2) - \Delta^{(1)}f(x_0, x_1)] / ((x_2 - x_0)(x_1 - x_0))$
- $c_3 = \Delta^{(3)}f(x_0, x_1, x_2, x_3) / ((x_3 - x_0)(x_2 - x_0)(x_1 - x_0))$   
 $= [\Delta^{(2)}f(x_1, x_2, x_3) - \Delta^{(2)}f(x_0, x_1, x_2)] / ((x_3 - x_0)(x_2 - x_0)(x_1 - x_0))$
- $\Delta^{(n)}$ s are forward differences of order n

The formula is given here. This is the Newton's interpolating formula. We also call it a forward interpolation. Forward interpolation because you will go from  $x_0$  to  $x_1$ ,  $x_1$  to  $x_2$  and so on. So my  $C_0$ , the first constant is the value of the function at  $x=x_0$ , okay. So this is my  $C_0$ .  $C_1$  is given by  $\Delta^{(1)}f(x_0, x_1) / (x_1 - x_0)$ . Now this  $\Delta^{(1)}f(x_0, x_1)$  is called a forward difference. What do I mean by the forward difference?

I have a function, I take the value of the function at  $x_1$ , subtract the value of the function at  $x_0$ . So this is the difference between  $f(x_1)$  and  $f(x_0)$ . This is the forward difference. So first order difference will be  $f(x_1) - f(x_0)$ . Second order difference will be, okay, I take 2 first order differences

and subtract to get a second order difference. That is what is given here.  $C_1$  is given in terms of first order difference  $\frac{f(x_1) - f(x_0)}{x_1 - x_0}$ .

$C_2$  is given by the second order difference  $\frac{f(x_2) - f(x_0)}{x_2 - x_0}$  and  $x_1 - x_0$ . What is my second order difference? Second order difference is I take the first order difference between  $x_1$  and  $x_2$ . What is the first order difference between  $x_1$  and  $x_2$ ?  $f(x_2) - f(x_1)$ . That is my first order difference between  $x_1$  and  $x_2$ , okay. Then  $\frac{f(x_1) - f(x_0)}{x_1 - x_0}$  will be the first order difference between  $x_1$  and  $x_0$ , that is  $f(x_1) - f(x_0)$ .

So first order difference at point  $x_1$ , first order difference at point  $x_2$ , the difference of the 2,  $\frac{f(x_2) - f(x_0)}{x_2 - x_0}$  and  $x_1 - x_0$ . So my  $C_2$  term is a coefficient for the second value.  $C_2$  is given by this.  $C_3$  is given in terms of a third order difference. What is a third order difference now? Third order difference will be the difference between 2 second order differences. What is  $f(x_0) \cdot x_2^2$ ?  $f(x_0) \cdot x_2^2$  is the second order difference which is already given here.

This is my second order difference at  $x_2$ . Now there is again a second order difference at  $x_3$ . So just as I have a second order difference at  $x_2$ , I can calculate a second order difference at  $x_3$ . So the difference between 2 second order differences is my third order difference. So that third order difference  $\frac{f(x_3) - f(x_0)}{x_3 - x_0}$ ,  $x_2 - x_0$  and  $x_1 - x_0$ . So this is my  $C_3$ . So this is the discussion on my Newton's interpolating polynomial of a third order polynomial.

Now suppose I want to extend to higher orders. If I want to extend to higher orders, I will need higher order coefficients. Say for  $C_3$ , I had a third order forward difference. For  $C_4$ , I will have a fourth order forward difference.  $C_5$ , I will have a fifth order difference. So one of the main strategies in interpolation is you do not use very high order polynomials. When you use very high order polynomials, the excess power is to very large values, like 10, 11, 12. So large polynomials have lot of fluctuation between adjacent points.

Because you know that at  $n$ th order polynomial has  $n$  0s. So higher order polynomials go through 0 many many times. So they are not good for interpolation. So best would be the third order interpolation and this is the Newton's formula that I have just indicated. Now my next thing

would be, I will take an example. I will take an example of a Newton's third order interpolating polynomial, that is what my next slide is going to be, okay. So look at this example. This example has data  $x$ , 4 values of  $x$  and 4 values of  $f(x)$ .

(Refer Slide Time: 14:54)

Example of Newton's Interpolation: Forward Differences

$x$	$f(x)$	$\Delta f$	$\Delta^2 f$	$\Delta^3 f$
0.0	1.0			
		0.391		
0.33	1.391		0.153	
		0.544		0.086
0.66	1.935		0.239	
		0.783		
0.99	2.718			

The first value of  $x$  is 0. The second value is 0.33. The third value is 0.66 and the fourth value is 0.99. So these are my 4 values of  $x$  and in the second column, I have 4 values of the function. What is my function? When  $x=0$ , the function is 1. When  $x=0.33$ , the function is 1.391. When  $x=0.66$ , my value is 1.935. And when  $x=0.99$ , my value is 2.718. So these are my 4 values of  $x$  and 4 values of  $f(x)$ .

So what is a first order difference. First order difference is the difference between  $f(x_1) - f(x_0)$ . So these are the 2 adjacent points. This is my first order difference, okay. This is the first order difference between  $x_1$  and  $x_0$ .  $x_1$  and  $x_0$ , this is  $f(x_1) - f(x_0)$ . The second order difference is  $f(x_3) - f(x_2) - f(x_2) - f(x_1)$ . The first order difference, this is the third one,  $f(x_3) - f(x_2)$ . So I have 3 first order difference between 4 points of the value of the function  $f(x)$ .

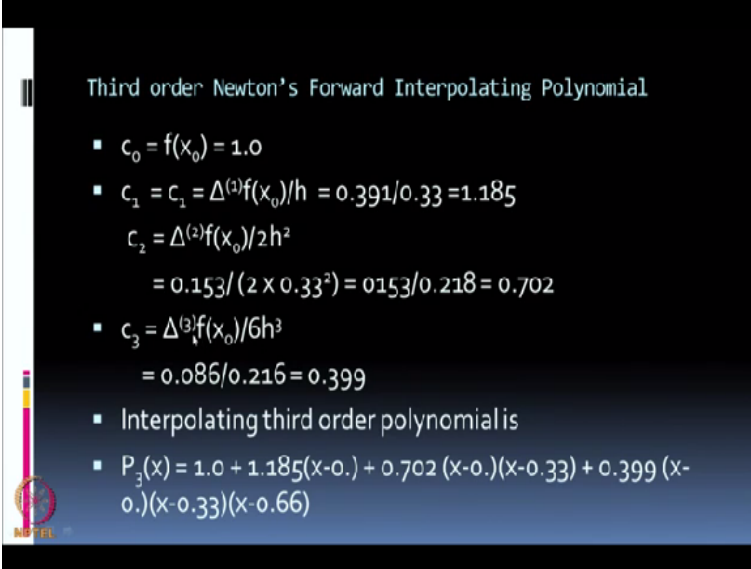

These are my 3 first order differences. How do I get my second order difference now? Second order difference will be the difference between the first order difference at the second point-the first order difference at the first point, okay. This is the first order difference. The difference between the 2 first order differences is my second order difference. So between the first 2 first

order differences, I got a second order difference.

Between the second 2 first order differences, I got the second second order difference. So there are 2 second order differences and finally I have a third order difference. What is the third order difference? It is the difference between 2 second order differences. This is my second order difference between the 3 points. This is my second order difference between the first 3 points. So the difference is my third order difference.

So once I have all these differences, now I can build a polynomial.

**(Refer Slide Time: 17:04)**

Third order Newton's Forward Interpolating Polynomial

- $c_0 = f(x_0) = 1.0$
- $c_1 = c_1 = \Delta^{(1)}f(x_0)/h = 0.391/0.33 = 1.185$   
 $c_2 = \Delta^{(2)}f(x_0)/2h^2$   
 $= 0.153/(2 \times 0.33^2) = 0.153/0.218 = 0.702$
- $c_3 = \Delta^{(3)}f(x_0)/6h^3$   
 $= 0.086/0.216 = 0.399$
- Interpolating third order polynomial is
- $P_3(x) = 1.0 + 1.185(x-0.) + 0.702(x-0.)(x-0.33) + 0.399(x-0.)(x-0.33)(x-0.66)$

My next slide will show you how I build that polynomial. Remember to build the polynomial, I need the values of C0, C1, C2 and C3. These are my values. What is C0?  $f(x_0)$  which is 1.0. C2 is second order difference at  $x_0/2h$  square. C3 is the third order difference/ $6h$  cube. This is how I calculate my differences, okay. So the first order C1 was first order difference/h, that is  $0.391/0.33$ , that is 1.185.

C2 was my second order difference/2 times h square. Now this h is the difference between adjacent points, okay. So 0.702 is my second coefficient. Now third coefficient is the third order difference at  $x_0/6h$  cube. So  $0.086/0.216$ , 0.399. So I have the 3 values of my coefficients and how do I get my polynomial now? Polynomial is  $P_3(x)=1.$

1 is nothing but value of  $C_0$ ,  $+x-x_0*1.185$ ,  $C_1$ ,  $+0.702$  which is the second value,  $*x-x_0*x-x_1$ . This is my  $x_0$ ,  $x_1$ . So this is  $x-x_0$ ,  $x-x_1$ . Finally the third value,  $0.399$ , that is my  $C_3$ ,  $*x-x_0*x-x_1*x-x_2$ . So now this is a polynomial which is an interpolating polynomial between these 4 points of data that I had. And with this function, I can calculate the values of the polynomial.

```

So now my next strategy would be, how do I program this. I will be describing all the lines of the program. Then I will actually execute the program and show you in my next hour. So before I go further, we want to make some points on these polynomials. I already mentioned that if you have 4 points, you can have a third order polynomial between these 4 points. Now if any function passes through these 4 points, any other way of getting this interpolating polynomial will give me the same polynomial.

There is a unique polynomial which will pass through these 4 points. I mean there is a theorem in algebra, you can actually prove that but I will not do this in my lecture. So between 4 points, there is a unique interpolating polynomial. So whether I do LaGrange interpolation or Newton's interpolation, I will get exactly the same result. So there is an interpolation, uniqueness of interpolation.

So now I will, let us see the difference between LaGrange method and Newton's method. In

Newton's method, what was required is that it is far more effective if the axes are spaced equally between each other. If you recall our data, what was our data? 0.33, 0.66, 0.99. If the data is even equally spaced, the whole process becomes very easy, okay. Whereas for lagrange interpolation, there is no requirement of any kind.

You can have any values of  $x_0, x_1, x_2, x_3$  and you can have an interpolating polynomial. So Newton's method is far more effective if they are equally spaced, okay. So now I shall start looking at the program. Now look at the program. I want to start the interpolating polynomial, okay. So this is my formulae for all the coefficients. This is how the program begins. So look at the program carefully.

The first line is the comment statement. It is always a good idea to have comment statements in the program because the moment you look at the program, you know what it is going to do. So the first line is the comment which says that the Newton's forward interpolating polynomial degree 3. And how is the comment card written? The first character is a c. Do not consider these squares here.

The left hand square are more the part of the ppt. Your actual first program, actual first column in the program starts with this column. This is the first column in your programming lines. First one is a comment card. Second one is also comment.  $P_n(x) = y_0 + c_1 + c_2$ , this is the polynomial, okay. So for  $f(x)$  in the interval  $x_0$  to  $x_n$ , that is my polynomial. Kth term, let us call it  $t_k$ , okay. So what algorithm I am going to use in my algorithm?

There will be input, okay. And then I will initialize the difference table. So remember, there are these, these are all forward differences, first order difference, second order difference, third order difference which we have called  $\Delta_1, \Delta_2, \Delta_3$ . I will initialize the differences. Then once I initialize the differences, I have all values of  $x$  and once I have all values of the table, I can calculate the value of the polynomial for any given  $x$ , okay.

And now our strategy would be, we are always going to use  $N+1$ , that is if it is, if there are 4 points, then I have a third order polynomial. This  $N$  would also refer to your degree of the

polynomial. So you have 4 data points here, okay at constant intervals.  $H$  is the interval between adjacent point, okay.  $N_{p1}$  is  $N+1$ . So these are all the comment cards which is part of the requirement for our own convenience.

Now I will start giving all the variables in the program. So what are my variables in the program?  $X$  is a variable, that is how many data points I have. This 10 is arbitrary. Instead of 10, I could have given 50 or 100. I could have given 4 also because I have 4 data points but normally I give larger dimensions because you may have large amount of data and you want to interpolate between adjacent points in that large amount of data.

So it is always good to declare dimensions which are much larger. So  $x$  is of dimension 10, that means the variable  $x$  can take 10 values.  $Y$  also is 10 because if there are 10 values of  $x$ , there will be 10 values of  $y$ . Then this  $\Delta y$  is my difference table. This is the forward difference table. So the maximum I will have is 10,10, right. Since there are only 10 data points, I will not even, when there are 10 data points, there will be 9 first order differences, there will be 8 second order differences, so maximum will be 10, so I have just defined a  $\Delta y$ .

This is an array, 10,10.  $c_s$  are for the coefficients.  $c_s$  are the coefficients, I have  $c_0, c_1, c_2$  and so on, okay. So then these  $T_s, P_Ns, X_{bar}$ , these are all,  $X_{bar}$  is a value at which I want to calculate the interpolated value. So these are not so important for our present purpose. So let us say I want to interpolate for some 100 points. What are these 100 points? Between the last value of  $X$  and the first value of  $X$ , I had 4 data points in my program.

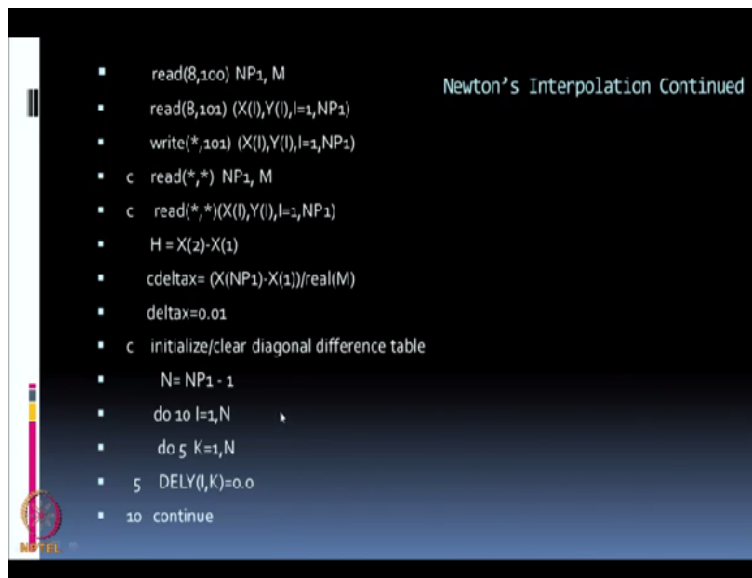

So what I want to do here? Is to calculate the value of the interpolating polynomial at those 100 points between  $X_0$  and  $X_N$ . So the number of points will be much larger than the data points I have because I have only 4 data points. At those 4 values of  $X$ , I already know  $f_x$ . So there is nothing to interpolate for the known values of those points. So I want to interpolate between all the  $X_s$  in the intermediate values.

So in this case, I have chosen 100 values. So for that purpose, I divide the interval between  $X_N$  and  $X_0$  into 100 values of  $X$ . So that is my division. So now I need to read the data from files

again. So open unit=8, file=interpolate.dat. This is my input file for my interpolation. Then whatever results I get, I am going to put in the output file. That is open file=Newton interpolation. So I am, for the output, I am giving newtintp as the output file, interp.dat as an input file.

Now why do I use this term interp and newtintp? So it tells me the moment I see interp, I know that it is a data for interpolation. And newtintp, so it has something to do with Newton's interpolation. So in this case, so file which has access by number 8, is the input file. File that is expressed by unit 12, will be the output file.

**(Refer Slide Time: 26:13)**

```
Newton's Interpolation Continued
▪ read(8,100) NP1, M
▪ read(8,101) (X(I),Y(I)),I=1, NP1
▪ write(*,101) (X(I),Y(I)),I=1, NP1
▪ c read(*,*) NF1, M
▪ c read(*,*)(X(I),Y(I)),I=1, NP1
▪ H = X(2) - X(1)
▪ cdeltax = (X(NP1) - X(1)) / real(M)
▪ deltax = 0.01
▪ c initialize/clear diagonal difference table
▪ N = NP1 - 1
▪ do 10 I = 1, N
▪ do 5 K = 1, N
▪ 5 DELY(I, K) = 0.0
▪ 10 continue
```

So my next things are the read statements, okay. I will read, so what I have to read? I have to read NP1, that is number of points +1, okay. If N was 3, our number of points was 4, okay. NP1 is N+1 and M is the number of points at which I want the interpolated polynomial, okay. So this Newton's interpolation method is not part of a program. So do not give any importance to this. This particular thing is not part of the program, okay.

So this is just for our reference that in this slide, I am discussing the Newton's interpolation method. So my next line was read 8 from that file 8 and NP1 and M. These are 2 integers. So I am going to read those 2 integers from file number 8. Next thing I want to read all the values of Xi and Yi. So how many are there? 4 values of Xi, 4 values of Yi, I going from 1 to NP1, okay.

So now this particular read statement, I am reading many many points without using a do loop.

So what this involves? This is called an implicit do loop. What is an implicit do loop? In the bracket, a do loop is already implicit because I want to say  $X_i, Y_i$ ,  $i$  going from 1 to NP1. NP1 is  $N+1$ . So there are NP1 points,  $i$  goes from 1 to NP1 and these values will be read. So a do loop is implicit. The moment I put in bracket  $X_i, Y_i$ ,  $i$  going from 1 to NP1, it will read all those NP1 values of  $X_i$  and  $Y_i$ .

Make sure you put these commas correctly. Because if any comma is missing, the do loop is not going to work properly, okay. So this is how I will read  $X_i$  and  $Y_i$ , okay. Next I am going to read from the, so in this particular case, after I read  $X_i$  and  $Y_i$ , I want to write on the screen. I want to write on the screen what are those values because many times you read something from a file, you do not know what is read.

So if whatever is read is shown on your screen, then you know exactly what you have read. So it is always a good idea whatever you read from a file, write the thing on the screen or write in some other file so that you can crosscheck that whatever you did was alright. So what I will do, I will conclude this lecture at this point. The next lecture, we will actually execute this program. We will execute the Newton's interpolating polynomial program.

We will execute the LaGrange interpolating program. And then you will see the results for yourself on the screen. So what we have discussed in this lecture? We have discussed the methods of interpolation. So there are many many methods. But we will use those methods which are easy for programming purpose.

So Newton interpolation is good because it is useful in many other areas such as integration, differential equations and so on. LaGrange's interpolation, it is a very nice thing to write a program for but Newton's is better because I can analyze the errors as well in this particular interpolation method. So I will conclude now. And the next lecture will be executing the entire program. Thank you.
