Lecture - 5B
Bearing Capacity of Shallow Foundation- Part 2

(Refer Slide Time: 00:17)

Now we will start Terzaghi's bearing capacity theory. Its first shallow foundations, let us draw a footing - this is your width B , depth of the foundation D_f , pressure intensity q_u , this is ϕ , this is ϕ , this has been called zone 1, this is your zone 2, this is your zone 3 and this will be q_u is equal to γD_f and this angle this angle will be 45° minus ϕ by 2.

First one is called elastic zone which will be immediately below the foundation, second is zone 2 is called radial shear zone or Prandtl's radial shear zone and zone 3 - zone 3 is your Rankine's passive zones.

So, what are the assumptions? Assumption is your footing is long and strip soil is semi infinite homogeneous and isotropic, soil semi infinite homogeneous isotropic soil fails by means of general shear failure, load is vertical and concentric load is vertical and concentric, base of the footing, base of footing it is rough and laid at shallow depth and shear strength is governed by, shear strength is governed by Mohr-coulomb equations. Terzaghi's bearing capacity theory how it has come? It has come from a earlier from the

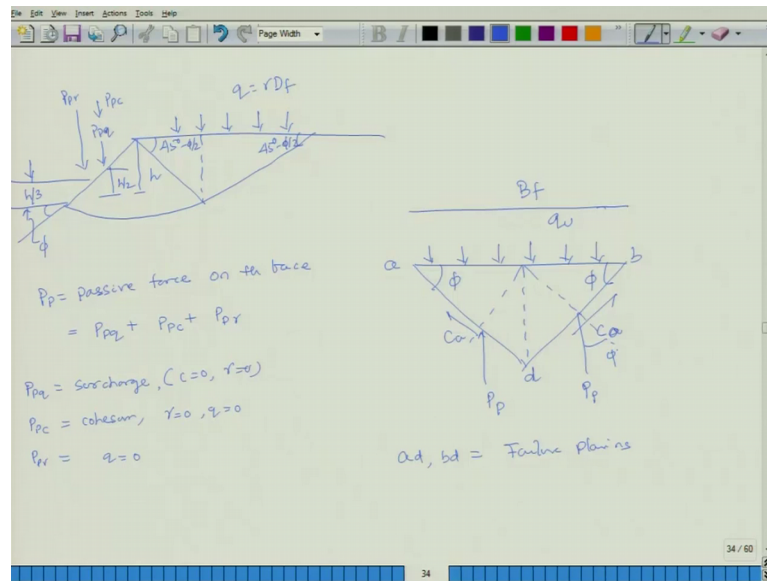

mechanical by electronic microscopic with a strip they observed that these kind of failure surface or particularly plastic sheets they observed.

So, Terzaghi is the person who was taken these observations and taken a shallow foundation there is a footing here and it is zone 1 2 3, here also zone 1, zone 2 and zone 3 it is symmetry both the sides. So, he classified based on that observation from mechanical of a polythene sheets by means electronic microscopic whatever the failure surface observed it has been implemented or taken for soil mechanics. Zone 1 is your elastic zone which will be immediately below the foundations - if I say this is my foundation, so this elastic zone will be immediately below your foundation, second one is your radial shear zone this is your radial shear zone, third one is your Rankine's passive zone and later on it has been modified Terzaghi's assumption is a footing is a long and strip, soil is in all geotechnical engineering problems, generally assumption is for soil it is semi infinite homogeneous and isotropic; that means, the properties are not changing.

Soil fails by means of general shear failure that is his assumptions and in this case load is vertical and concentric, base of the footing is rough laid at shallow depth shear strength is governed by Mohr column equations these assumptions you can say that may be these are the limitations of Terzaghi proposed bearing capacity. The exact solution it is a long one, I will just Gibbs doing the free body diagram, so that you can have an idea how these exact solution has been done, but it is out of this scope.

Now, the derivation part is coming what we are going to get it from here, we are going to get it a bearing capacity equations.

(Refer Slide Time: 08:21)

Now let me come back to 2 free body diagrams, 2 free body diagrams. So, let me take it half of this whatever I have shown it earlier half of this from here this surface to this surface I am taking it back. So, how it looks?

So, now I can name it or I can mark this forces this is your q is equal to $\gamma D f$, this will be your $45 \text{ degree} - \phi / 2$ and this is also $45 \text{ degree} - \phi / 2$ and here this angle will be, this will be your ϕ , this will be your ϕ and there will be different terms 1 is your $p p \gamma$ other is your $p p c$ and $p p \gamma$ if I put it here from here to here it will be $h / 2$ and here it is your h , and then sorry it is not $p p \gamma$ it will be $p p q$, then it is a $p p \gamma$ $p p \gamma$ this will be $h / 3$.

Now, particularly if I write it $p p$, if I write it $p p$, $p p$ is your passive force $p p$ is your passive force on the face, on the face then it will be $p p q$ plus $p p c$ plus $p p \gamma$. If you look at the notations $p p q$ passive force due to surcharge, $p p c$ passive force due to cohesion, $p p \gamma$ passive force due to your unit weight.

So, generally how he has solved it may be at the end slightly I can say it is out of this scope. So, it has been super imposed. Considering $p p q$ other 2 part has been neglected, considering $p p c$ other the 2 part has been neglected free body diagram has been drawn, considering $p p \gamma$ also other 2 part has been neglected and free body diagram has been drawn then it has been super imposed then it has been super imposed. So, if I write in case of $p p q$. So, $p p q$ what is that part? This is because of your surcharge, surcharge

then in that case c is equal to 0 gamma is equal to 0 then p pc by soil cohesion by soil cohesion in that case gamma is equal to 0 q is equal to 0 then p p gamma in that case by weight of soil in shear zone. So, in that case q is equal to 0.

These are the cases. So, if I am taking it to a middle part of this free body diagram if I make it in this bigger one let it be a b d, let it be a b d. So, this will be your I am drawing the free body diagram, this will be your q u and this is phi and this is your phi, here is your ca here is your ca then I wrote it, it is completely p p, p p is your p pq, p pc and p p gamma. Here I wrote it then this side also it is p p it makes an angle phi.

This is my free body diagram and width of the foundation is your D f. I am taking the elastic zone part I am taking the elastic zone part. So, ad and bd of the elastic zone are the failure plains rising at an angle to the horizontal ad and db, ad and bd of the elastic base are failure plains, failure plains. So, if I take this free body diagram let me write it out downward force downward force that is your q u into B into 1, q u into B into 1 I am writing it only B width of the foundation only B.

(Refer Slide Time: 14:20)

Downward Force

$$q_u \times B \times 1 \text{ (Load Transmitted)}$$

$$\frac{\gamma B^2}{4} \tan \phi \text{ (wt of wedge)}$$

Upward force

Total passive Resistance

Vertical component of cohesion force c

$$\frac{\gamma B^2}{4} \tan \phi + q_u B = 2P + 2C \sin \phi$$

$$c = c \times da = c \times db = c \times \frac{B/2}{\cos \phi}$$

$$q_u B = 2P_p + Bc \tan \phi - \frac{\gamma B^2}{4} \tan \phi$$

$$= 2(C_{p_{pq}} + P_{pc} + P_{pg}) + Bc \tan \phi - \frac{\gamma B^2}{4} \tan \phi$$

$2P_{pc} - \frac{\gamma B^2}{4} \tan \phi = B \times \frac{1}{2} \times \gamma B N_q$
 $2P_{pc} + Bc \tan \phi = Bc N_c$
 $2P_{pg} = B \gamma N_q$

$$q_u = c N_c + q_u N_q + 0.5 \gamma B N_q$$

$$q_w = c N_c + \gamma D_f N_q + 0.5 \gamma B N_q$$

$N_c N_q$ } Bearing Capacity factors
 N_q } ϕ

So, downward force q u load intensity major width into 1, this is your load transmitted. So, then weight of the soil wedge gamma B square by 4 tan phi this is your weight of wedge, this is your downward force downward force and upward force total passive resistance up upward force is your total passive resistance. Then vertical component of

cohesion c vertical component of cohesion force, force c ; if I write it qB which is equal to $2 p \text{ plus } 2 c \sin \phi$ here I am writing plus $\gamma B^2 \text{ by } 4 \tan \phi$.

Look at here once again downward force this is the free body diagram of the elastic zone downward force - $q u \text{ into } B \text{ into } 1$ because it has been assumed is a long, it is a 2 dimensional problem and plain strain if it is a plain strain per meter length, $q u \text{ into } B$ per meter length is a 1, this is a vertical force acting downward. Then within this wedge what is the weight of the wedge? Weight of the wedge is your $\gamma B^2 \text{ by } 4 \text{ into } \tan \phi$ then look at the upward force total $p p$, it may be $p p$ is $p p q$, $p p c$ and $p p \gamma$ is that upward force and this c , $c a$ or c has 2 component - one is your vertical component, one is your lateral component.

So, lateral component will equal and opposite and it will cancel out. So, vertical component will are your upward force, now here it is your $2 p p \text{ plus } 2 c \sin \phi$, now I can write it capital C is equal to small c unit cohesion into $d a$ which is equal to $c \text{ into } d B$. Capital C is equal to $c a$ or c unit cohesion small c $d a$ over the length this $d a$ over the length this $d B$ which is equal to again which is equal to $c \text{ into } B \text{ by } 2 \text{ by } \cos \phi$, c over the length here which will be $B \text{ by } 2 \cos \phi$. So, if I am writing it here I am putting it $q u$, $q u \text{ into } B$ which is equal to $2 p p \text{ plus } B c$, $B c \tan \phi$ minus $\gamma B^2 \text{ by } 4 \tan \phi$. As I said the $p p$ has 3 component it is your total passive. So, $p p \gamma$, $p p q$ and $p p c$, if I write it so this will be again $2 p p q - q$ is your surcharge, $p p c$ this is your cohesion plus $p p \gamma$ unit weight plus $B c \tan \phi$ minus $\gamma B^2 \text{ by } 4 \tan \phi$.

Now, let writing in this way let $2 p p \gamma$ minus $\gamma B^2 \text{ by } 4 \tan \phi$ which is equal to $B \text{ into half } \gamma B N \gamma$, then $2 p p c$ with this is because of your unit weight, this is because of your cohesion plus $B c \tan \phi$ which is equal to $B c N c$ and $2 p p q$ which is equal to $B q N q$. Why it has been rearranged like this? We have to bring out in a dimensionless form $N c$, $N q$ and $N \gamma$ are called bearing capacity factors and if you look at here if I am saying $p p \gamma$ because of your unit weight, unit weight which part is coming? This is a weight of the wedge I am taking it here this minus this footing into $B \text{ into half } \gamma B \text{ by } 2 \text{ into } N \gamma$.

If I am talking about the unit cohesions, this will be your $2 p p c$ unit cohesions plus $B c \tan \phi$ around the periphery how your cohesion force this is your $B c N c$, $N c$ is your

bearing capacity factor considering cohesions, p q surcharge Bq or Bqu , Bq or Bqu Nq . If I am rewriting it, if I am rewriting it q u is equal to all the terms if I am rewriting it, it will be $C Nc$ plus $q Nq$ plus $0.5 \gamma B N \gamma$ or $C Nc$ plus $\gamma D f Nq$ plus $0.5 \gamma B N \gamma$. This is your Terzaghi's bearing capacity theory, ultimate bearing capacity q_u is equal to $C Nc$, look at here definitions q_u is your ultimate bearing capacity $C Nc$ plus $\gamma D f Nq$ plus $0.5 \gamma B N \gamma$ and Nc , Nq , $N \gamma$ these are all your bearing capacity factors, bearing capacity factors it depends on ϕ .

So, this is all total in detail details you have to take a free body diagram individually then calculate it and Nc , Nq , $N \gamma$ are the bearing capacity factors.

(Refer Slide Time: 22:42)

The image shows a whiteboard with handwritten mathematical formulas for bearing capacity factors. On the left side, three equations are listed: $N_c = \cot \phi \left[\frac{a^2}{2 \cos^2(\frac{\pi}{4} + \frac{\phi}{2})} - 1 \right]$, $= (N_q - 1) \cot \phi$, $N_q = \frac{a^2}{2 \cos^2(\frac{\pi}{4} + \frac{\phi}{2})}$, and $N_r = \frac{1}{2} \tan \phi \left(\frac{K_{pr}}{\cos^2 \phi} - 1 \right)$. On the right side, the equation $a = \exp \left[\frac{3\pi}{4} - \frac{\phi}{2} \right] \tan \phi$ is written, followed by the definition $K_{pr} = \text{passive earth pressure coefficient}$. At the bottom right, the values $\phi = 0$, $N_c = 5.7$, $N_q = 1$, and $N_r = 0$ are noted.

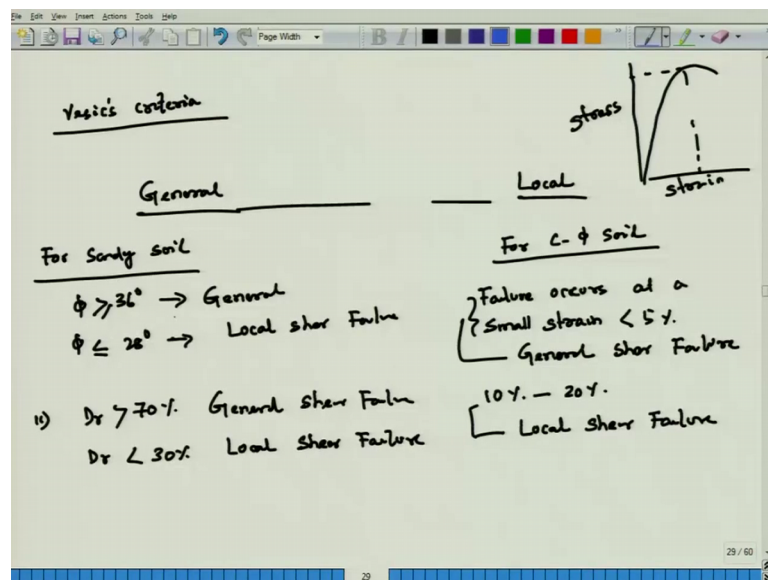

If I write it Nc , Nq , $N \gamma$ after the detail solutions bearing capacity factor for cohesions it will be $\cot \phi$ a square by $2 \cos$ square π by 4 plus ϕ by 2 minus 1 which is equal to you can write it Nq minus 1 into $\cot \phi$. Nq is equal to bearing capacity factor for your surcharge a square by $2 \cos$ square π by 4 plus ϕ by 2 $N \gamma$ is equal to half $\tan \phi$ $k p \gamma$ by \cos square ϕ minus 1 . So, this is a after solving all free body diagram individually taking into considerations integrating if I write it Nc , Nq and $N \gamma$ we will come into in this form. So, basically it depends on your ϕ depends on your ϕ . So, a , what is a ? a is exponential 3π by 4 minus ϕ by 2 into $\tan \phi$, $k pr$ is equal to passive earth pressure coefficient.

So, this is your bearing capacity factors and ultimate bearing capacity as per Terzaghi's bearing capacity theory you have to remember this, this will be required throughout your foundation design. $C N_c \gamma D_f N_q + 0.5 \gamma B N_\gamma$ or $C N_{cq} N_q + 0.5 \gamma B N_\gamma$. Once you know the ϕ value you can find it out bearing capacity factors N_c , N_q and N_γ when ϕ is equal to 0, ϕ is equal to 0 N_c is equal to 5.7, N_q is equal to 1, N_γ is equal to 0.

So, Terzaghi has given a bearing capacity factor chart that you can keep it for examination point of view. For different value of ϕ N_c , N_q has been given. So, in between ϕ it has been given 0 - 10 degree, 20 degree, 30 degree, 40 degree, 50 degree like this given in between you have to interpolate, you have to interpolate this value of your N_c , N_q and N_γ . So, this is about your Terzaghi's bearing capacity ultimate bearing capacity of your foundations resisting of your soil to find it out considering a general shear failure.

Later on Terzaghi has modified if there is a local shear failure local shear failure if you go back to as I have said which cases it will be your local shear failure.

(Refer Slide Time: 26:14)

ϕ is greater than or equal to 36 degree general shear failure it has been assumed for sandy soils. Local shear failure if it is ϕ is less than equal to 28 degree then it is a local shear failure.

(Refer Slide Time: 26:40)

Terzaghi (1943)

$$c_m = \frac{2}{3} c$$

$$\tan \phi_m = \frac{2}{3} \tan \phi$$

Local shear Failure

$$q_u = \frac{2}{3} c N_c' + q N_q' + 0.5 \gamma B N_\gamma'$$

Modification for square and circular Footing

$$\text{Square} \Rightarrow q_u = 1.3 c N_c + \gamma D_f N_q + 0.4 \gamma B N_\gamma$$

$$\text{Circular} \Rightarrow q_u = 1.3 c N_c + \gamma D_f N_q + 0.3 \gamma B N_\gamma$$

$q_u = c N_c + \gamma D_f N_q + 0.5 \gamma B N_\gamma$

So, in this case for local shear failure Terzaghi has given empirical relations for adjustment, Terzaghi which has proposed 1943. So, you have to consider mobilized cohesion equal to two-third c , $\tan \phi_m$ is equal to two-third $\tan \phi$. Now ultimate bearing capacity for your considering local shear failure q_u is equal to two-third $C N_c$ prime effective in terms of if it is a ϕ effective, there will be a total stress as well as there will be effective stress plus $q N_q$ prime plus $0.5 \gamma B N_\gamma$ prime this is what he has given the modifications for these case local shear failures.

So, now again he has modified for your square and circular footings we will solve also problems in this case how it will going. First one Terzaghi has given for it considering it is a cohesion less soil considering $c \phi$ soils considering it is general shear failures q_u is equal to $C N_c$ plus $q N_q$ plus $0.5 \gamma B N_\gamma$. Then later in 1943 as modified for your considering it is as local shear failure q_u is equal to two-third, $C N_c$ prime $q N_q$ prime plus $0.5 \gamma B N_\gamma$ prime.

Now, again he has modified because initially assumption it has been considered for a strip footing. Again he has been modified for square as well as circular footing. Now for square footing q_u is equal to $1.3 c N_c$ plus $\gamma D_f N_q$ plus $0.4 \gamma B N_\gamma$ and for circular footing circular footing q_u is equal to $1.3 C N_c$ plus $\gamma D_f N_q$ plus $0.3 \gamma B N_\gamma$. Look at initial bearing capacity considering general shear failure for a strip formulations q_u is equal to $C N_c$ plus $\gamma D_f N_q$ plus 0.5γ

B N gamma, this is what initially he has given for a strip footing considering general shear failure.

Now, it has been modified for your considering local shear failure, again it has been modified for square as well as circular, square what are the terms? $1.3 C N_c$ and 0.4, instead of 0.5 it is 0.4, here it is $1.3 C N_c$ here it is 0.3. This modification based on the studies, based on some few experiments studies he has been modified.

Then, I think I will stop it here. Next class I will start the effect of the water table, after finishing this effect of water table I will solve few problems I will solve few problems how to calculate your bearing capacity ultimate bearing capacity before I go for other bearing capacity theories basics and Meyerhof's because these are all preliminary part, basic part how to calculate your bearing capacity of foundation resisting on soils, then once it is over we will go for settlement analysis then once that is over then we will go for different foundation designs.

Thank you.
