Analysis of Strain – VI

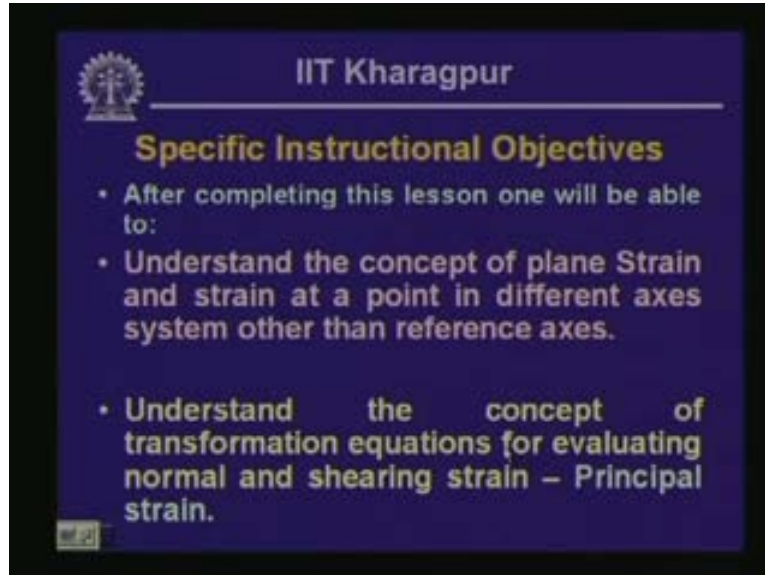

Welcome to the 6th lesson on module 2 which is on analysis of strain.

(Refer Slide Time: 00:56)

In the last lesson we have discussed some aspects of strain which occurs due to change in temperature material and we had looked into the aspects of lack of heat in a system and the stresses and strain which is generated thereby. And in this particular lesson we are going to discuss some more aspects of strain analysis.

(Refer Slide Time: 01:44)

The slide is a presentation slide from IIT Kharagpur. It features the IIT Kharagpur logo in the top left corner and the text 'IIT Kharagpur' in the top right. The main title is 'Specific Instructional Objectives' in a bold, yellow font. Below the title, there are three bullet points in white text on a dark blue background. The first bullet point says 'After completing this lesson one will be able to:'. The second bullet point says 'Understand the concept of plane Strain and strain at a point in different axes system other than reference axes.'. The third bullet point says 'Understand the concept of transformation equations for evaluating normal and shearing strain – Principal strain.'. There is a small logo in the bottom left corner of the slide.

It is expected that once this particular lesson is completed one should be able to understand the concept of plane strain at a point in different axes system other than reference axes. In general when we refer to the strain, we refer in terms of ϵ_x , ϵ_y , γ_{xy} in plane strain. If we orient the axes system other than the rectangular axes system which we consider then what will be the difference in strain value.

One should be able to understand the concept of transformation equations in fact for evaluating the strain at different orientation of axes, we need to evolve the equations which we term as transformation equations for evaluating normal and shearing strain. Thereby we will come across the maximum value of the normal strain which is analogous with the traces we will term them as principal strain. So we will look into how to evaluate the values of principal strain and at which orientation this principal strains act at that particular point.

(Refer Slide Time: 02:52)

IIT Kharagpur

Scope

- **This lesson includes:**
 - Recapitulation of previous lesson.
 - Evaluation of plane strain at a point on different axes system using transformation equations.
 - Concept of Principal strains and principal angles.
 - Examples for the evaluation of strains at a point due to change of axes.

Hence this particular lesson includes recapitulation of previous lesson. In fact as we have done in the past, we will be discussing the questions and in the process we will recapitulate the aspects which we had looked into. Evaluation of plane strain at a point on different axes system using transformation equations and thereby the concept of principle strains and principle angles will generate from these equations of transformation and we look into some examples for the evaluation of strains at a point due to the different orientation of axes system from the rectangular axes system.

(Refer Slide Time: 3:50)

IIT Kharagpur

Answers to Question Set 2.5

- What is meant by misfit and what are its consequences?
- What is the principle of a double acting turn-buckle?
- What is the pitch of a bolt and how is it related to the displacement of the nut?

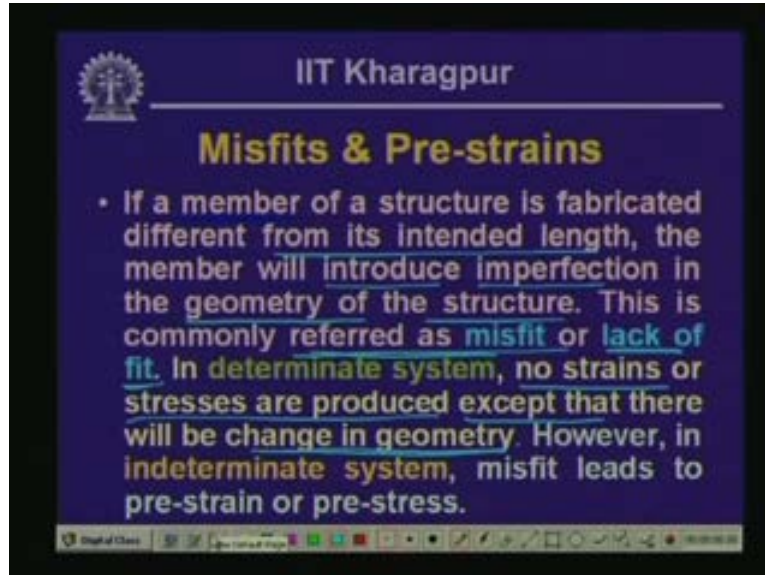

Let us look into the answers. The first question was what is meant by misfit and what are its consequences?

(Refer Slide Time: 3:57)

In any system, if a particular member of a particular length is manufactured or fabricated in such a way that it varies from its original length then there is a problem of fitting that particular member into the whole structural system and that leads to some problems. If the system is a determinate one, the geometrical arrangement of the whole structural system will be in problem but there would not be any stresses or strains generated within that particular system. But if the structural system is an indeterminate one, then this length of the member which is not right which could be longer or shorter can induce strains and thereby stresses in such members and thereby if a member of a structure is fabricated different from its intended length then the member will introduce imperfection in the geometry of the structure.

(Refer Slide Time: 05:30)

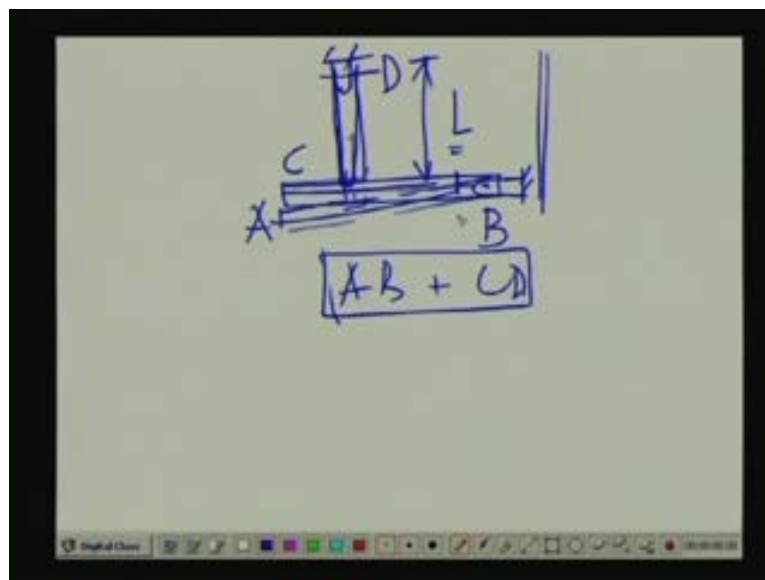

IIT Kharagpur

Misfits & Pre-strains

- If a member of a structure is fabricated different from its intended length, the member will introduce imperfection in the geometry of the structure. This is commonly referred as misfit or lack of fit. In determinate system, no strains or stresses are produced except that there will be change in geometry. However, in indeterminate system, misfit leads to pre-strain or pre-stress.

Now this is commonly referred as misfit or lack of fit now for a determinate system no strains or stresses are produced except that there will be change in geometry this aspect we have discussed last time.

(Refer Slide Time: 07:01)

A hand-drawn diagram illustrating a misfit in a structural assembly. A horizontal bar is shown with points A and B marked. A vertical member CD is positioned above the bar, with its length labeled as L. The diagram shows the member CD being inserted into the assembly, with a gap between it and the bar. Below the diagram, a box contains the text $AB + CD$.

Let us say we have a bar which is supported at this particular point and we have one member here connected at this point and let us say this is member AB, this is member CD. If this particular member CD which is of length l, if this particular length differs; if it is shorter or longer than l then when we try to fit in this particular member CD into whole assembly there is a possibility that by changing the geometry of this particular system, for example if CD is longer

than l then this particular member may undergo rotation over here to accommodate the longer length of CD. So, in the process the geometry of the whole system AB and CD which is consisting of these two members will be different than as expected because the geometry of this particular system looks like this bar will no longer be horizontal but it will be inclined. But in the process no strains or stresses will be introduced in this particular member.

(Refer Slide Time: 07:24)

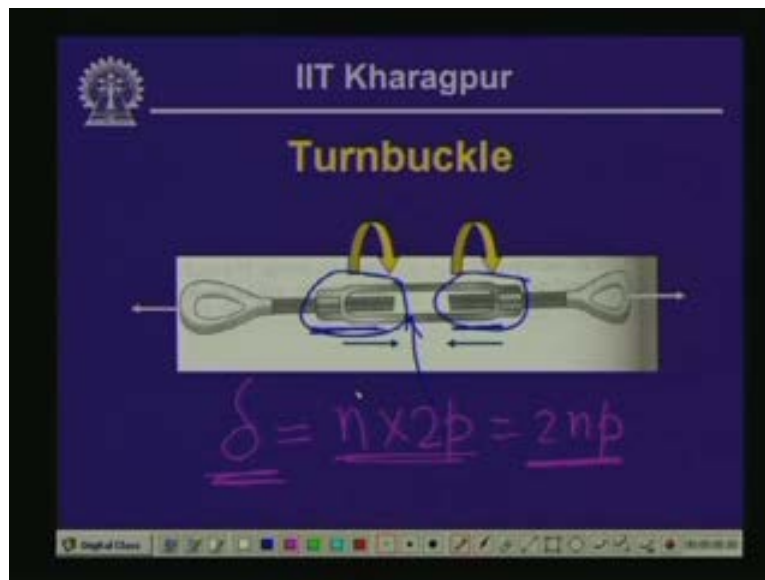

(Refer Slide Time: 08:15)

But if we have a system which is indeterminate, then this particular misfit will lead to pre-strain or pre-stress. The next question posed last time was, what is the principle of a double acting turnbuckle?

Now if we remember that we introduce the lack of heat by introducing or turning this kind of system which we call as turn-buckle. Here we have the threaded part in this particular zone and this particular part which is equivalent to or not in the whole system and if this whole assembly is rotated, we have one threaded part in this particular zone and another threaded part in this particular zone. On one side if the whole assembly is rotated on right hand side, we have a thread on the left hand side also we have a thread. It is like the whole thing is rotated and there will be movement of the screw towards inside or if we are rotating on the other side the screw will move outside. Thereby there will be change in the length of the whole screw assembly system either inside or outside.

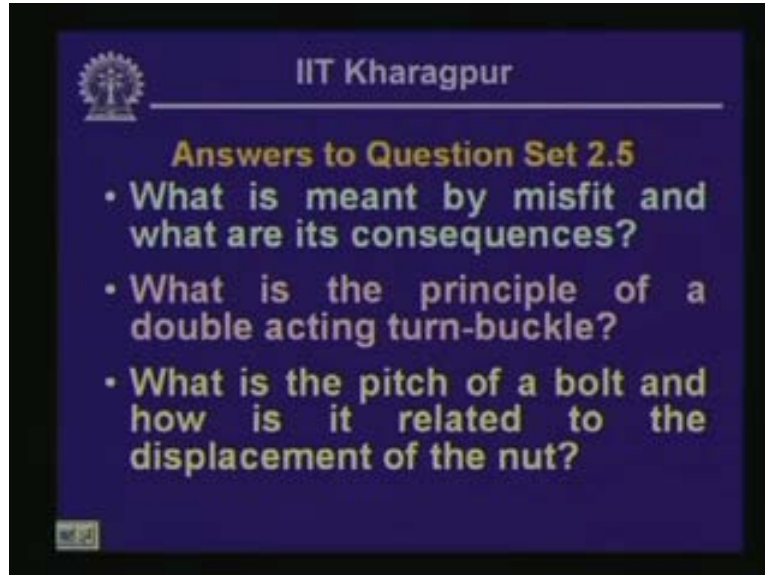

(Refer Slide Time: 09:53)

Since in one turn both the screws moving and as we had defined last time that by one turn of a knot or by one turn of this turn buckle, the movement of the knot for one 360 degree revolution, the movement we call as pitch which we had defined as p , now if we give a turn buckle by one full revolution then both the screws are moving by one pitch. So thereby there is a total movement of the whole turn buckle by an amount which is $2p$.

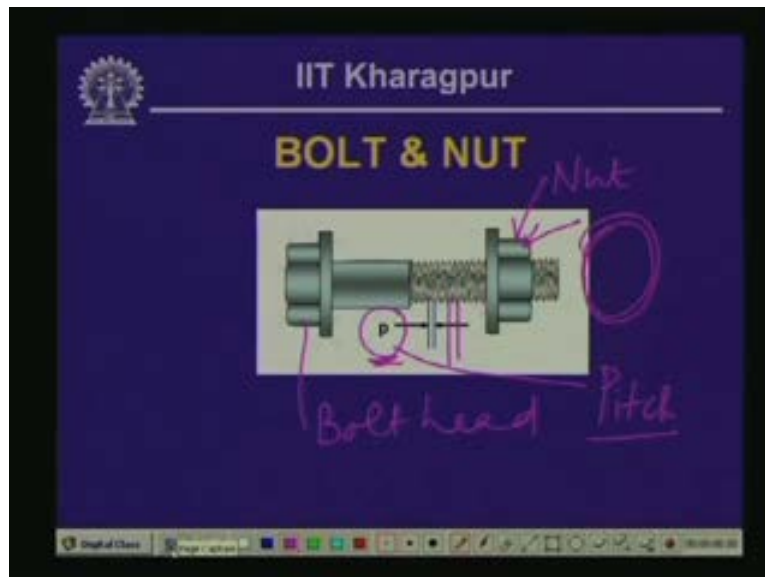

If we have n number of turns given n into $2p$ will be the total movement of this turn buckle. So that deformation Δ or the deformation which we are introducing by turning this turnbuckle will be equal to $2np$. This is the system or the principle on which it works which can be introduced where we need to introduce the tensile or the axial pull or we like to reduce the length by turning the screws of the turnbuckle.

(Refer Slide Time: 10:16)

Now the third question similar to the second one is what the pitch of a bolt is and how is it related to the displacement of the nut?

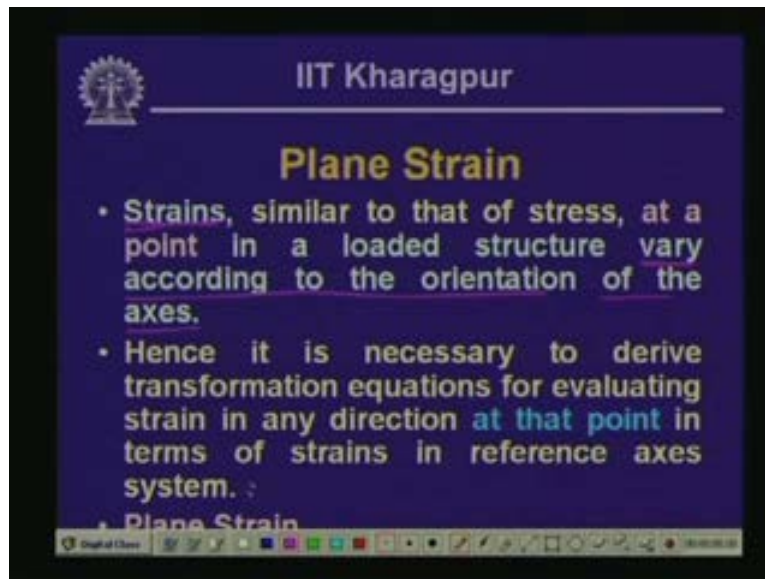

(Refer Slide Time: 11:26)

Let us look in to this nut bolt assembly. Here this is the nut and this is the bolt assembly, this is the bolt head. When we turn this nut, this nut is turned on for one full revolution of 360 degrees. The nut moves along the length of the threaded part by these two peaks and these consecutive two peaks in fact is denoted by letter p which we call as pitch. So one movement or one turn of the nut over the full circle moves the nut by a distance p and this is what is the displacement of the nut by giving a full circle turn along the threaded part of the bolt.

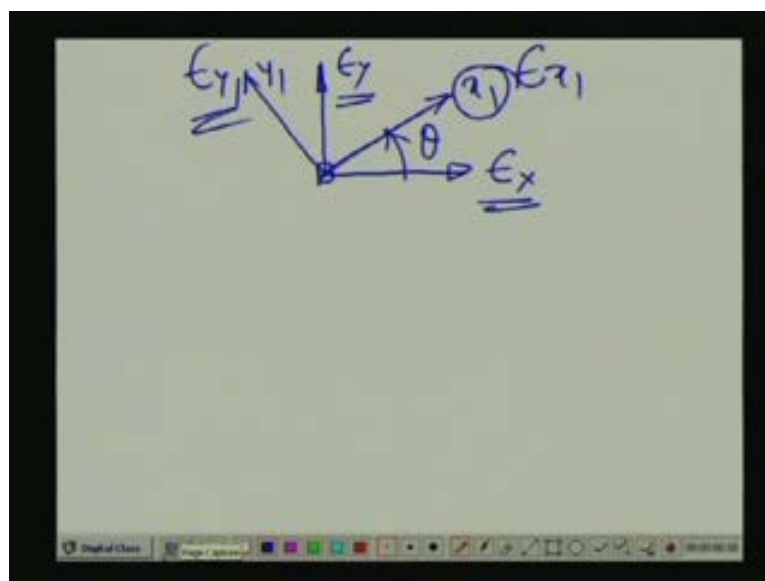

Now let us look into the strain that we are looking for at a particular point. We are defining the strain with reference to the rectangular axes system as normal strain in the x direction as ϵ_x , normal strain in the y direction as ϵ_y and the normal strain in the z direction as ϵ_z .

(Refer Slide Time: 12:14)

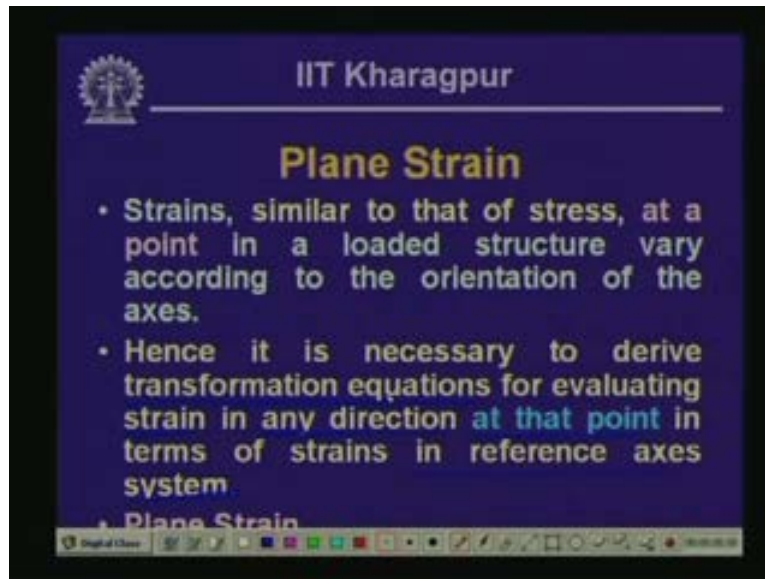

Now it is similar to the situation as we had in case of stresses. The strain at a particular point in a loaded structure varies according to the orientation of the axes. If we have a rectangular axes system then what stress we are expecting?

(Refer Slide Time: 13:13)

For example, we are interested to evaluate the stress strain at this particular point. Now at this particular point the strain which we are referring with reference to the rectangular axes system ϵ_x and ϵ_y , if we try to find out the strain at this point at a different orientation of the axes; let us call this as axes x_1 y_1 now the strain corresponding to this as ϵ_{x_1} and ϵ_{y_1} will be different from ϵ_x and ϵ_y . Our objective is to find out the strain along this orientation or in the orientation of the axes which could be in the general form as theta at any orientation with reference to x and y plane or x and y reference axes so that we can compute the strain at that particular point at different orientation.

(Refer Slide Time: 13:43)

Hence it is necessary to derive the transformation equations for evaluating strain in any direction at that particular point in terms of strains in reference axes system. Before we go in to the evaluation of transformation equations let us look into what we really meant by the plane strain condition.

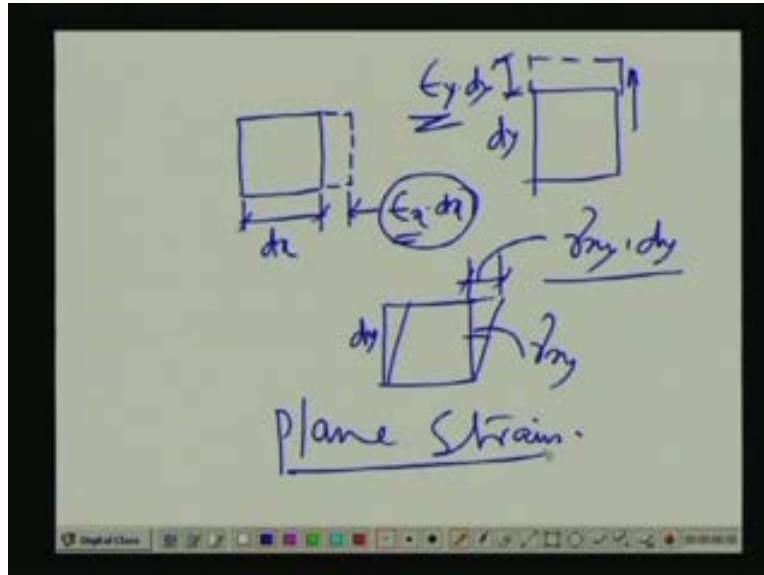

(Refer Slide Time: 15:14)

At a particular point the strains are represented in this particular form. This is the small part in a material and these are the reference axes x , y and z . The strains acting on this in the x direction is ϵ_x , ϵ_y as the normal strain and ϵ_z in the z direction. We have the strain components which are ϵ_x , ϵ_y and ϵ_z the normal strains and the shear strains are γ_{xy} , γ_{yz} and γ_{zx} . So these are the six strain components which will be acting at this particular point with reference to this rectangular axes system.

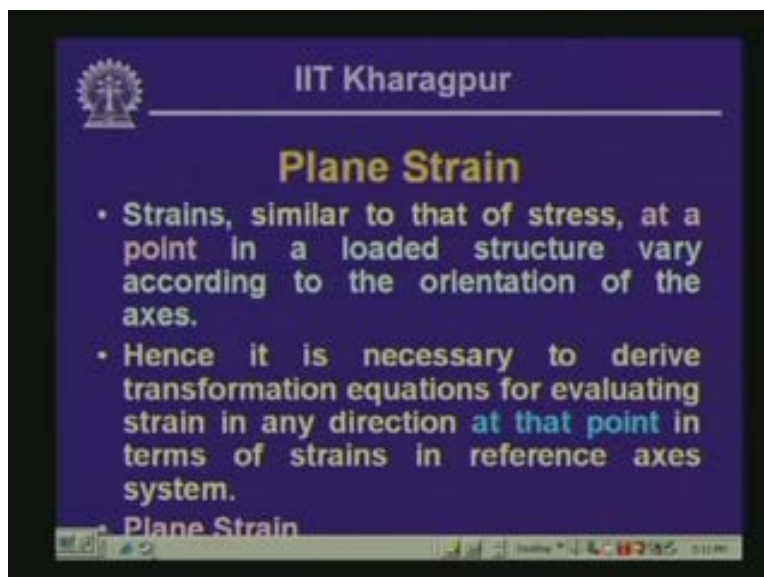

Now if we like to represent the strain on a plane which is the z plane having x and y axes the strain that will be existing will be ϵ_x , ϵ_y and γ_{xy} and rest of the strains like ϵ_z , γ_{yz} and γ_{zx} are 0. So this particular condition of strain we term as plane strain condition. That means these strains will be acting in this particular plane either in the front part or at the backside which is represented by this x and y axes system which is basically the z plane.

(Refer Slide Time: 17:16)

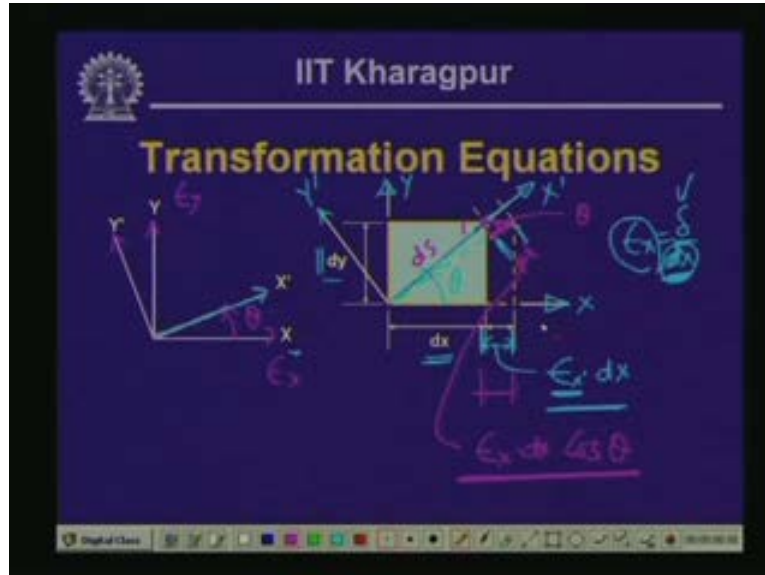

Now in this plane if we like to find out the strains corresponding to three different directions, if we consider the material in this particular plane, in the x direction when it is stretching it is undergoing deformation in this particular direction and if we say this length as dx , then it will undergo stretching in this particular direction which is $\epsilon_x dx$ where ϵ_x being the strain and dx being the original length then the elongation is $\epsilon_x dx$ or it can have stretching in the y direction this length is dy so this stretching is $\epsilon_y dy$ where ϵ_y is the strain in the y direction. Or if we have the shearing strain which is γ_{xy} then the extension is equal to $\gamma_{xy}(dy)$ if we call this depth as dy . So these are the extensional aspects when we talk in terms of the strain in the plane, these are related to the plane strain conditions.

(Refer Slide Time: 17:16)

(Refer Slide Time: 17:22)

Now let us look into the transformations. We are interested to evaluate what will be the strain values at that particular point if we orient the axes with reference to our rectangular axes system. If it is oriented at an angle of theta with reference to x axis then if we are interested to find out the strains we should look into how to compute it and what are the corresponding equations which we term generally as transformation equation. Now x and y are the reference rectangular axis and the strain corresponding to these directions are ϵ_x and ϵ_y as we are defining. We are interested to evaluate the strain at this point with reference to the axes system x dashed and y dashed which is at an angle of theta with reference to x axes.

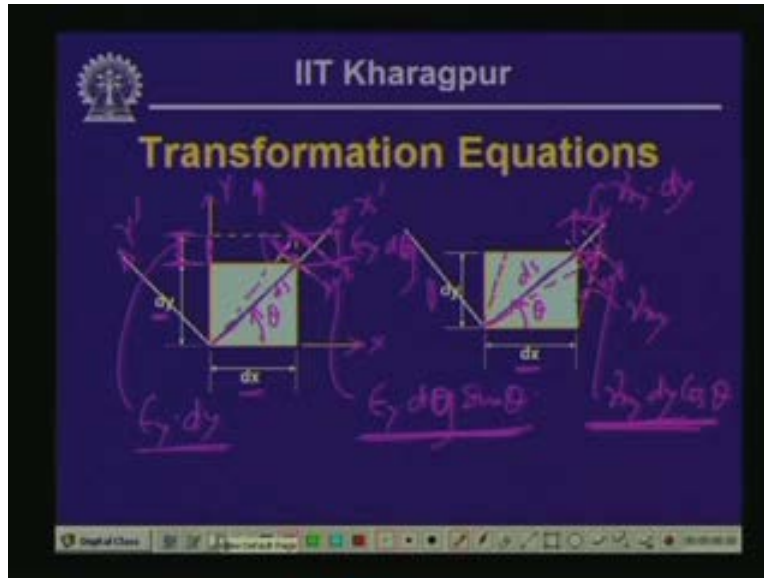

Let us consider different cases which are corresponding to the plane strain situation in which this is the length dx, this is length dy. Now we consider that the axis x prime lies along the diagonal of this particular element which we have considered of length dx and dy. Thereby this diagonal direction is our x prime axis and perpendicular to that is our y prime axis, this is the rectangular x and y direction. When this particular element is getting stretched in the x direction the extension in the x direction is given by this particular length which is equal to $\epsilon_x(d_x)$ and ϵ_x is the strain in the x direction.

As we know strain is equal to δ by dx delta by the original length so original length multiplied by ϵ_x ϵ_x will give you the extension delta. If we are interested to know how much extension this diagonal has undergone with reference to this ϵ_x , this particular part is the diagonal after it has undergone extension.

Now this particular angle is theta as we have defined that x prime axis is lying along the diagonal. Hence x prime axis is making an angle of theta with x so this particular angle is theta. If this is the horizontal distance $\epsilon_x dx$ which is equal to this, and since this angle is theta, this is theta and this particular one also we are calling as theta then the extension of the diagonal is horizontal distance times cos theta which is equal to; so this particular extension is given as $\epsilon_x dx \cos \theta$. This is the extension of the diagonal. Let us call that this particular

diagonal is of length d_s so originally it had a length of d_s and it is undergoing an extension which is in terms of ϵ_x which is $\epsilon_x dx \cos \theta$ because of the extension in the x-direction.

(Refer Slide Time: 25:16)

Now let us look into what happens if it undergoes strain in the y direction and thereby the shearing strain. When this particular element undergoes the strain having length dx and dy and it is undergoing strain in the y direction so this is x axis. As we had defined this is y axis and as for our definition we said that the diagonal of this particular element is representing the x prime axis and perpendicular to that is the y prime axis. This is the angle θ and here in the y direction it is undergoing extension thereby the extension which is given by this particular length from its original form length is equals to $\epsilon_y dy$ so $\epsilon_y dy$ ϵ_y is the extension of this element and because of this stretching the diagonal which was originally of length d_s now, is getting changed. This is the change length of the diagonal and extension is given by this particular part of the diagonal which is equals to now this angle θ , thereby this particular angle also is θ so this is θ . Now this horizontal extension is given by $\epsilon_y dy \sin \theta$ hence the extension which is happening is equals to $\epsilon_y dy \sin \theta$ of this which is equal to this particular extension and this extension is given by $\epsilon_y dy \sin \theta$. $\epsilon_y \sin \theta$ $\epsilon_y \sin \theta$ $\epsilon_y \sin \theta$ ϵ_y is the vertical extension and the component along the diagonal direction is $\epsilon_y dy \sin \theta$.

Similarly, the element which is of size $dx dy$ undergoing a shearing strain and because of shearing strain it is having the shearing strain angle which is γ_{xy} . Thereby the diagonal which was originally of length d_s is undergoing extension which is of this particular form and thereby the extension of this, is given by this particular length and again this angle is θ as we have defined θ hence this is θ . So the extension which is this stage is given by now this particular extension because of shearing strain is equals to $\gamma_{xy} dy$ and the extension in the diagonal is equals to is given by $\gamma_{xy} dy \cos \theta$. So we have three extensions of the diagonals obtained now in the previous case where it was getting stretched in the x direction. We have the extension as $\epsilon_x dx \cos \theta$. In case of stretching in the y direction or

strain in the y direction we have extension of the diagonal as $\epsilon_y d_y \epsilon_y \sin \theta$ and the shearing strain the stretching of the diagonal is equal to $\gamma_{xy} d_y \cos \theta$. Hence the total stretching of the diagonal if we look in to the total stretching of the diagonal.

(Refer Slide Time: 28:32)

$$\begin{aligned} \Delta d &= \delta x + \delta y + \delta s \\ &= \epsilon_x dx \cos \theta + \epsilon_y dy \sin \theta + \gamma_{xy} dy \cos \theta \\ \epsilon_{x'} = \epsilon_d &= \frac{\Delta d}{ds} = \frac{\epsilon_x \frac{dx}{ds} \cos \theta + \epsilon_y \frac{dy}{ds} \sin \theta + \gamma_{xy} \frac{dy}{ds} \cos \theta}{1} \\ \epsilon_{x'} &= \epsilon_x \cos^2 \theta + \epsilon_y \sin^2 \theta + \gamma_{xy} \sin \theta \cos \theta \end{aligned}$$

Let us call that as delta d, this is given by the extension due to ϵ_x plus ϵ_x extension in the diagonal due to ϵ_y plus ϵ_y extension due to γ_{xy} . These are given as $\epsilon_x dx \cos \theta$ plus $\epsilon_y dy \sin \theta$ plus $\gamma_{xy} dy \cos \theta$. So these are the three extensions we have obtained now if we propose that all three cases because of the plane strain condition, then this is the extension delta d we get for the diagonal one hence the strain in the diagonal direction which is that of $\epsilon_{x'}$ prime.

Now $\epsilon_{x'}$ prime are the strain in the x prime direction is nothing but the strain in the diagonal is equals to the extension of the diagonal divided by its original length and this is nothing but equals to Δd divided by ds which is equals to $\epsilon_x dx \cos \theta$ by ds plus $\epsilon_y dy \sin \theta$ by ds plus $\gamma_{xy} dy \cos \theta$ by ds .

Now if I look into the diagram from which we have evaluated this extension dx by ds is again $\cos \theta$ dy by ds is nothing but $\sin \theta$. Hence the whole thing gives us; this is equal to $\epsilon_x \cos^2 \theta$ plus $\epsilon_y \sin^2 \theta$ plus $\gamma_{xy} \sin \theta \cos \theta$. So $\epsilon_{x'}$ prime is the strain in the x direction. In terms of the strain ϵ_x ϵ_y and γ_{xy} is given as $\epsilon_x \cos^2 \theta$ plus $\epsilon_y \sin^2 \theta$ plus $\gamma_{xy} \sin \theta \cos \theta$. Now this expression called epsilon prime further can be simplified now writing $\cos^2 \theta$ as in terms of $\cos 2\theta$.

(Refer Slide Time: 31:10)

$$\epsilon_{x'} = \epsilon_x \cdot \frac{1}{2} (1 + \cos 2\theta) + \epsilon_y \cdot \frac{1}{2} (1 - \cos 2\theta) + \frac{\gamma_{xy}}{2} \sin 2\theta$$

$$\epsilon_{y'} = \frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$$

$$\epsilon_{y'} = \frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos (180 + 2\theta) + \frac{\gamma_{xy}}{2} \sin (180 + 2\theta)$$

Let us write $\epsilon_{x'}$ as equal to ϵ_x in place of $\cos^2 \theta$ write this as $\frac{1}{2} (1 + \cos 2\theta)$ plus ϵ_y $(\frac{1}{2} (1 - \cos 2\theta))$ plus $\frac{\gamma_{xy}}{2} \sin 2\theta$. Now $\frac{1}{2} (1 + \cos 2\theta)$ gives $\frac{1}{2} (1 + \cos 2\theta)$ so this is equal to $\frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$ so this is the expression for $\epsilon_{x'}$ or the strain in the x' direction in terms of the strain ϵ_x , ϵ_y and γ_{xy} or $\frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$.

Similarly, we can compute the value of $\epsilon_{y'}$ from the expression of $\epsilon_{x'}$ now since the y' axis is at 90 degrees with reference to x' this is being 90 degrees. If we place θ as $\theta + 90$ we can get the strain in the one y' direction so it is $\epsilon_{y'}$. We can write as $\frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos (\theta + 90)$, θ is $\theta + 90$ which is $180 + 2\theta$ plus $\frac{\gamma_{xy}}{2} \sin (\theta + 90)$. Now this will give us the value of strain with the y' direction and $\cos (180 + 2\theta)$ is equal to $-\cos \theta$ and $\sin (180 + 2\theta)$ is equal to $-\sin 2\theta$.

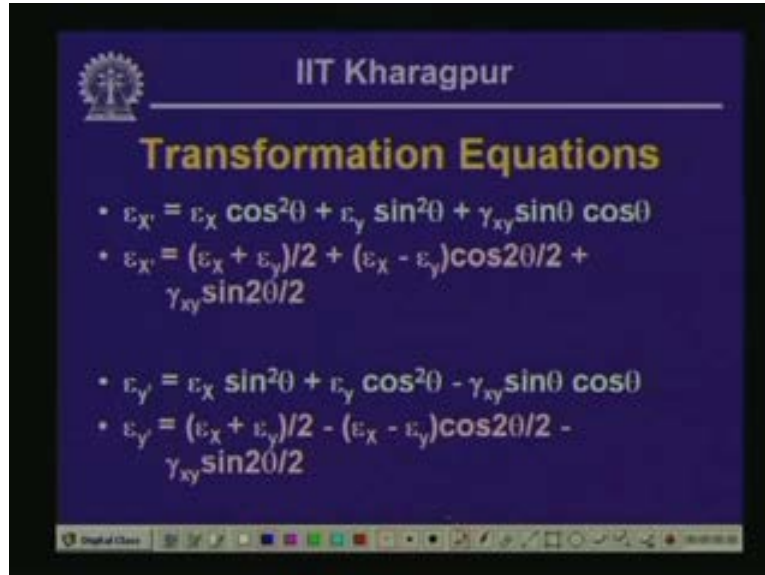

(Refer Slide Time: 32:17)

$$\epsilon_{y'} = \frac{\epsilon_x + \epsilon_y}{2} - \left(\frac{\epsilon_x - \epsilon_y}{2}\right) \cos(2\theta) - \frac{\gamma_{xy}}{2} \sin(2\theta)$$
$$\therefore \boxed{\epsilon_{x'} + \epsilon_{y'} = \epsilon_x + \epsilon_y}$$
$$\epsilon_{y'} = \frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2}\right) \cos(180 + 2\theta) + \frac{\gamma_{xy}}{2} \sin(180 + 2\theta)$$

So the expression called $\epsilon_{y'}$ prime is equal to then $\epsilon_{x'}$ plus $\epsilon_{y'}$ by 2 minus $\epsilon_{x'}$ minus $\epsilon_{y'}$ by $2\cos 2\theta$ minus γ_{xy} by $2\sin 2\theta$ and interestingly, if we note here that if we add this $\epsilon_{x'}$ prime plus $\epsilon_{y'}$ prime this gives us the value of the equation as $\epsilon_{x'}$ plus $\epsilon_{y'}$ now because other terms gets cancel hence $\epsilon_{x'}$ prime is equal to $\epsilon_{y'}$ prime.

If you remember, when we had evaluated the stresses at a point with reference to different orientation of axes we had seen that the total stress values remain constant. The values of σ_x plus σ_y is equal to $\sigma_{x'}$ plus $\sigma_{y'}$ if it is oriented at a different angle and the same thing holds good for the strain as well as the strain with reference to rectangular axes system $\epsilon_{x'}$ plus $\epsilon_{y'}$ is equal to $\epsilon_{x'}$ prime plus $\epsilon_{y'}$ prime with reference to x' prime and y' prime axes.

(Refer Slide Time: 33:35)

IIT Kharagpur

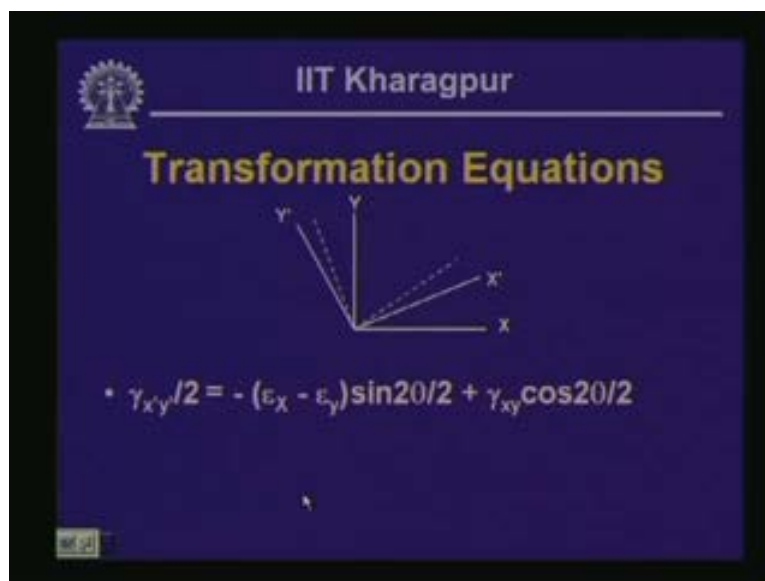

Transformation Equations

- $\epsilon_{x'} = \epsilon_x \cos^2\theta + \epsilon_y \sin^2\theta + \gamma_{xy} \sin\theta \cos\theta$
- $\epsilon_{x'} = (\epsilon_x + \epsilon_y)/2 + (\epsilon_x - \epsilon_y)\cos 2\theta/2 + \gamma_{xy} \sin 2\theta/2$
- $\epsilon_{y'} = \epsilon_x \sin^2\theta + \epsilon_y \cos^2\theta - \gamma_{xy} \sin\theta \cos\theta$
- $\epsilon_{y'} = (\epsilon_x + \epsilon_y)/2 - (\epsilon_x - \epsilon_y)\cos 2\theta/2 - \gamma_{xy} \sin 2\theta/2$

Digital Class

These are the values which we have just now seen that $\epsilon_{x'}$ prime is equal to $\epsilon_x \cos^2\theta + \epsilon_y \sin^2\theta + \gamma_{xy} \sin\theta \cos\theta$ and $\epsilon_{x'}$ prime in terms of $\cos 2\theta$ and $\sin 2\theta$ given as $(\epsilon_x + \epsilon_y)/2 + (\epsilon_x - \epsilon_y)\cos 2\theta/2 + \gamma_{xy} \sin 2\theta/2$ and thereby $\epsilon_{y'}$ prime is equal to $\epsilon_x \sin^2\theta + \epsilon_y \cos^2\theta - \gamma_{xy} \sin\theta \cos\theta$ which eventually comes as $(\epsilon_x + \epsilon_y)/2 - (\epsilon_x - \epsilon_y)\cos 2\theta/2 - \gamma_{xy} \sin 2\theta/2$ so these are the values of the strain with reference to x' and the y' prime axis.

(Refer Slide Time: 33:40)

IIT Kharagpur

Transformation Equations

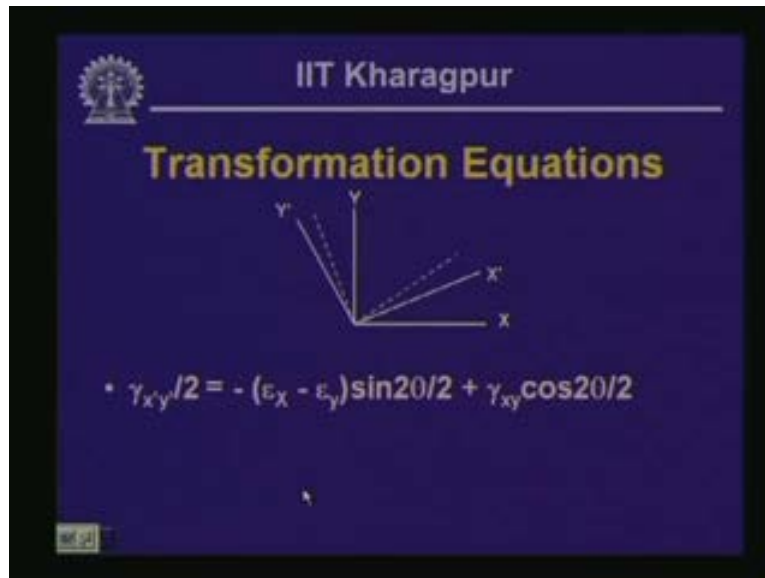

- $\gamma_{x'y'}/2 = -(\epsilon_x - \epsilon_y)\sin 2\theta/2 + \gamma_{xy} \cos 2\theta/2$

1

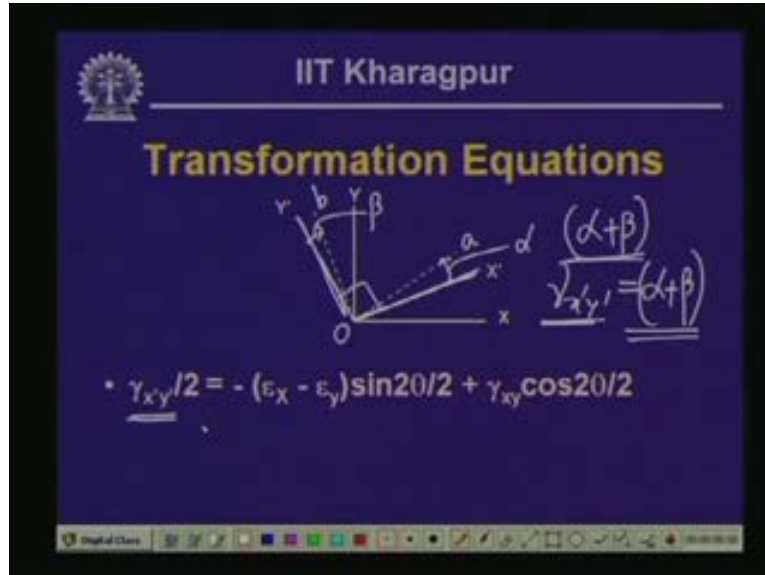

Now what we need to do is, since we said that, under plane strain condition we have three strain components which are ϵ_x , ϵ_y and γ_{xy} so under the changed or the oriented axes system with reference to x' and y' we will have the strains which are equivalent to the plane strain situation which are $\epsilon_{x'}$, $\epsilon_{y'}$ and $\gamma_{x'y'}$ and $\gamma_{x'y'}$ we call as the shearing strain with reference to x' and y' axis. Now, let us evaluate the value of the shearing strain with reference to x' and y' axis.

(Refer Slide Time: 34:24)

As we know that shearing strain is the angle which is changed from its original 90 degree position. If we have two reference axes which is at 90 degrees with each other the shearing strain causes the change in this 90 degrees angle.

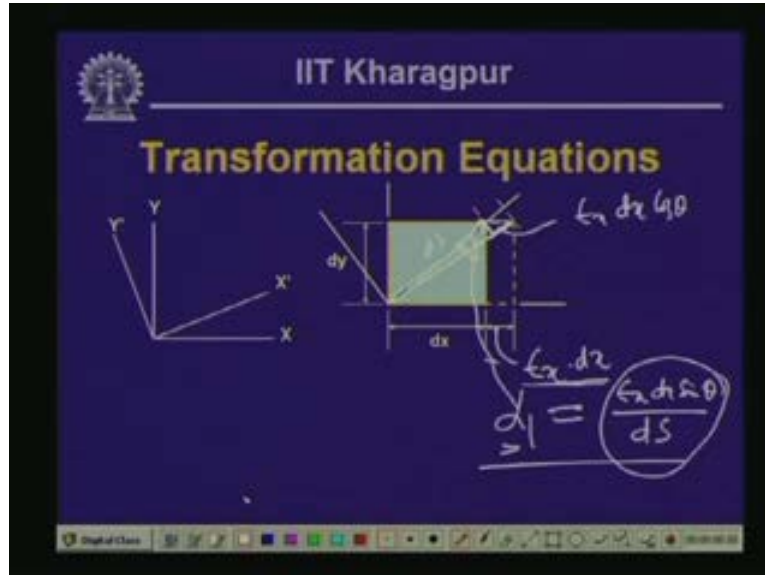

(Refer Slide Time: 35:43)

So here in this particular case when we try to change, evaluate the shearing strain $\gamma_{x' y'}$ let us assume that we had a line oa which was originally lying along this $o x'$ now and a line ob originally, which was lying on the line $o y'$ now because of the shearing strain. They have undergone a change and let us call this changed angle as α and this changed angle as β , thereby the total change is $\alpha + \beta$ from the original 90 degrees of $o x'$ $o y'$ and this change is the shearing strain $\gamma_{x' y'}$ so $\gamma_{x' y'}$ is equal to $\alpha + \beta$.

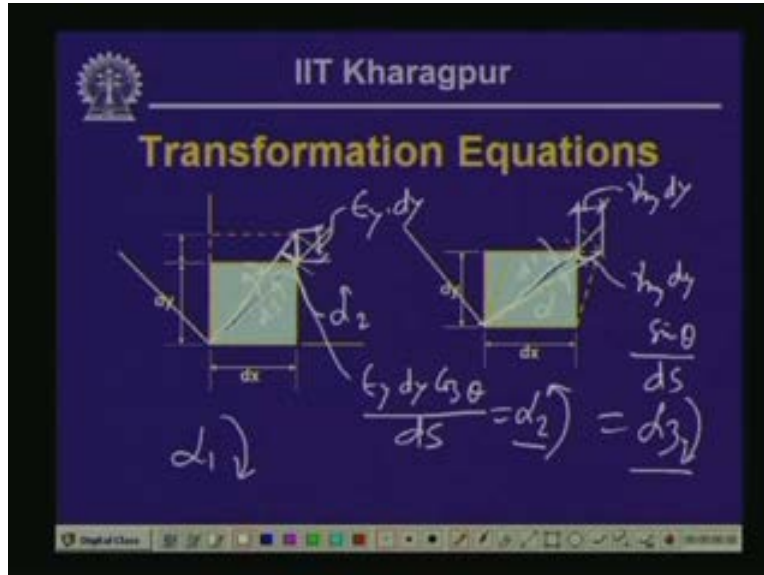

Now what we need to do is corresponding to the three changes that we have seen in case of plane strain corresponding to stretching in the x direction stretching in the y direction and because of the shearing strain that the diagonal which is along the x dashed axis had undergone changes. The diagonal head changes in the angle and if we join those angles together we will get the final position of the diagonal. Similarly, the line which is along $o y'$ which is originally we are designated as ob now under its changed consideration after it has undergone deformation. It has come to position ob , so there is a change in the angle from $o x'$ $o y'$ to oa and ob . This changed angle will give us the value of the shearing strain.

(Refer Slide Time: 38:22)

Now to compute those angles let us go back. In this particular case where we computed it the deformation of the diagonal which was originally ds then finally it came to this particular position. Now here we have already seen that this particular extension is $\epsilon_x dx$ and this particular stretching of the diagonal was $\epsilon_x dx \cos \theta$. This is the angle that has been changed because of this stretching so let us call this angle as α_1 and then the α_1 can be given as this divided by this distance. Now this particular length is nothing but the extension which is $\epsilon_x dx (\sin \theta)$. So α_1 is equal to $\epsilon_x dx \sin \theta$ by ds . So $\epsilon_x dx \sin \theta$ by ds is the angle, α_1 is equal to this. Now please note that that this particular angle is undergoing a change in the clockwise direction. Let us look in to the deformation that we are getting corresponding to the other two cases.

(Refer Slide Time: 40:22)

Now in this particular case the deformation which we have the diagonal this is the original length ds and because of the stretching in the y direction this has taken this particular form. Thereby this is the extension in this particular direction so let us call this angle change as α_2 and this angle change is in an anticlockwise form. Whereas in the previous case it was in the clockwise direction and the horizontal stretching of this particular element is $\epsilon_y dy$ as we have seen and this particular angle is θ . So this stretching is equal to $\epsilon_y dy \cos \theta$ and that divided by the original length ds will give the value of angle α_2 .

Similarly, when we have the shearing strain the diagonal was original length of ds finally it has taken the form which is here and the extension of this particular length in terms of the shearing strain is $\gamma_{xy} dy$. Again, since this angle is θ this particular value is $\gamma_{xy} dy \sin \theta$ and that divided by ds will give us the angle α_3 which is again in the clockwise direction so this is equal to α_3 . Therefore we have three angles α_1 , α_2 , α_3 and please note that angle α_1 is in the clockwise direction angle, α_2 is in anticlockwise direction and angle α_3 is in clockwise direction.

(Refer Slide Time: 43:18)

IIT Kharagpur

Transformation Equations

$$\alpha = -\epsilon_x \sin^2 \theta + \epsilon_y \cos^2 \theta - \gamma_{xy} \sin 2\theta$$

$$\gamma_{x'y'/2} = -(\epsilon_x - \epsilon_y) \sin 2\theta / 2 + \gamma_{xy} \cos 2\theta / 2$$

$$\alpha = -\alpha_1 + \alpha_2 - \alpha_3$$

$$= -\frac{\epsilon_x \frac{dx}{ds} \sin \theta}{\cos \theta} + \frac{\epsilon_y \frac{dy}{ds} \cos \theta}{\sin \theta} - \frac{\gamma_{xy} \frac{dx}{ds} \frac{dy}{ds}}{\cos \theta \sin \theta}$$

When we are computing the strain here which is we have designated as α and this particular angle is α which is in an anticlockwise direction so α is equal to minus α_1 which is in a clockwise direction plus α_2 which is anticlockwise direction minus α_3 which is again in a clockwise direction so this state value gives in the anticlockwise direction and if we sum up this values of α we get the values as α one we got as $\epsilon_x dx \sin \theta$ so this is equal to minus $\epsilon_x dx \sin \theta$ by ds plus α_2 is equal to $\epsilon_y dy \cos \theta$ by ds minus α_3 is equal to $\gamma_{xy} dy \sin \theta$ by ds .

Now again dx by ds as we have seen is $\cos \theta$ dy by ds is equal to $\sin \theta$ dy by ds is equal to $\sin \theta$ and dy by ds again is $\sin \theta$. So this expression turns out to be α is equal to minus $\epsilon_x \sin \theta \cos \theta$ plus $\epsilon_y \sin \theta \cos \theta$ minus $\gamma_{xy} \sin^2 \theta$. Now note that this is the value of the angle α . Similarly, we will have to compute the value of β which is taken by the length ob from its original position. Therefore oy' has come to this particular position by changing this angle β , so α plus β sum will give me the angle γ between x' and y' now β can be computed from the expression of α itself by placing θ as $\theta + 90$. Also, noting the fact that α is computed in an anticlockwise direction whereas β is in a clockwise direction so if we substitute for θ as $\theta + 90$.

(Refer Slide Time: 45:29)

The slide from IIT Kharagpur, titled "Transformation Equations", shows a diagram of a coordinate system with axes \$x, y\$ and \$x', y'\$. The angle between \$x\$ and \$x'\$ is \$\alpha\$, and between \$y\$ and \$y'\$ is \$\beta\$. The angle between \$x\$ and \$y'\$ is \$\theta\$. The equations shown are:

$$\alpha = -\epsilon_x \sin \theta \cos \theta + \epsilon_y \sin \theta \cos \theta - \gamma_{xy} \sin^2 \theta$$

$$\gamma_{xy}/2 = \frac{-(\epsilon_x - \epsilon_y) \sin 2\theta/2 + \gamma_{xy} \cos 2\theta/2}{2}$$

$$\beta = \frac{\epsilon_x \sin(\theta+90) \cos(\theta+90) - \epsilon_y \sin(\theta-90) \cos(\theta+90)}{2}$$

$$= -\epsilon_x \sin \theta \cos \theta + \epsilon_y \sin \theta \cos \theta + \gamma_{xy} \sin^2 \theta$$

Now writing down for beta which is the negative of this, because it is going in a clockwise direction it is $\epsilon_x \sin$ of theta plus 90 \cos of theta plus 90 minus $\epsilon_y \sin$ of theta plus 90 \cos of theta plus 90 plus $\gamma_{xy} \sin$ of theta plus 90 square. The signs have been changed because beta is in the clockwise form and alpha was in anticlockwise form. Now this gives us the values as; again \cos theta and \sin theta which is negative so this is minus $\epsilon_x \sin$ theta \cos theta, this is again plus $\epsilon_y \sin$ theta \cos theta and this is $\gamma_{xy} \cos$ square theta. So if we add this alpha and beta we get the value of γ_{xy} x prime and y prime.

The γ_{xy} x prime y prime is equal to alpha plus beta. If we add them up we get $\epsilon_x \sin$ theta minus 2 $\epsilon_x \sin$ theta \cos theta 2 $\epsilon_y \sin$ theta \cos theta and $\gamma_{xy} \cos$ square theta minus \sin square theta, $\gamma_{xy} \cos$ square theta minus \sin square theta will give you \cos 2theta and 2 \sin theta \cos theta will give you \sin 2theta. If we write down γ_{xy} x prime y prime by two forms it gives us γ_{xy} x prime y prime is equal to minus $(\epsilon_x - \epsilon_y) \sin$ 2 theta by 2 plus $\gamma_{xy} \cos$ 2theta by 2 so this is the value of the shearing strain γ_{xy} x prime y prime.

IIT Kharagpur

Principal angles & Strains

- Principal angles may be calculated from:
$$\tan 2\theta_p = \frac{\gamma_{xy}}{\epsilon_x - \epsilon_y}$$
- Value of Principal strains are:
$$\epsilon_{1,2} = \frac{(\epsilon_x + \epsilon_y)}{2} \pm \sqrt{\left(\frac{(\epsilon_x - \epsilon_y)}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2}$$

Now from this we can compute the values of the principle strains and the angle of principle planes which is given by twice $2\theta_p$ and the principle strain as ϵ_1 ϵ_2 . This is similar to the one which we computed for the principle stresses and the principle angles. If you remember when we had computed the stresses we evaluated them in the same form, and this gives us the value of principle strains and the principle angles.

IIT Kharagpur

Example Problem - 1

$\delta = -\epsilon$

Diagram of a compound bar fixed between two supports. The bar consists of three segments: bronze (800 mm), aluminum (500 mm), and steel (400 mm). A force P is applied at the right end. The bar is initially stress-free.

- The compound bar - initially stress-free. Compute stress in each material if temperature drops by 30°C . Walls do not yield. $A_{br}=2400 \text{ mm}^2$; $A_{al}=1200 \text{ mm}^2$; $A_{st} = 600 \text{ mm}^2$ $\alpha_{br} = 19.0 \times 10^{-6} / ^\circ\text{C}$; $\alpha_{al} = 23.0 \times 10^{-6} / ^\circ\text{C}$; $\alpha_{st} = 11.7 \times 10^{-6} / ^\circ\text{C}$ $E_{br}=83 \text{ GPa}$; $E_{al}=70 \text{ GPa}$; $E_{st}=200 \text{ GPa}$

Here is a problem to look at. The compound part which is made out of bronze, aluminum and steel are supported between these two supports and the stress in each of these material is to be computed because of the drop in the temperature by 30 degree C and here what is to be noted is

that the walls do not yield and the properties of the cross-sectional area of the bronze part, cross-sectional area of aluminum part, cross-sectional area of steel part are given and corresponding thermal expansion coefficients and the modulus elasticity values are given.

Here the point to be noted is that, if we remove this support then if we allow these bars to undergo changes because of the change in the temperature then there will be shortening because that is a reduction in the temperature so there will be deformation in delta which will be negative. Now we will we will apply a force p to pull this bar and bring it to this particular position and thereby there will be stresses.

(Refer Slide Time: 49:13)

$$\begin{aligned} \delta &= 19.0 \times 10^{-6} \times 30 \times 800 \\ &+ 23 \times 10^{-6} \times 30 \times 500 \\ &+ 11.7 \times 10^{-6} \times 30 \times 400 \\ \delta &= -0.9414 \text{ mm.} \\ -0.9414 &= \frac{P \times 400}{600 \times 200 \times 10^3} + \frac{P \times 500}{1200 \times 70 \times 10^3} + \frac{P \times 800}{2400 \times 83 \times 10^3} \\ P &= 70.8 \text{ kN (Tension)} \end{aligned}$$

So if we compute the values of deformation delta this is equal to $19.0(10 \text{ caret minus } 6)(30)$ is the temperature times the length $\alpha_1 \alpha_t$ plus $23(10 \text{ caret minus } 6)$ is the alpha hence 3 into 1 plus $11.7(10 \text{ caret } 6)(30)(400)$. This gives us a shortening of 0.9414 mm and when we pull this by load p then the this elongation 0.9414 is to be compensated by the force which is p into l by a which is $600(200)(10 \text{ caret } 3)$ plus p into 500 into $1200(70)(10 \text{ caret } 3)$ plus $p(800)$ by $2400(83)(10 \text{ caret } 3)$ equal to the values of extension.

(Refer Slide Time: 49:47)

Handwritten calculations on a whiteboard:

$$\sigma_{br} = 29.5 \text{ MPa}$$
$$\sigma_{Al} = 59.0 \text{ MPa}$$
$$\sigma_{st} = 118 \text{ MPa}$$
$$P = 70.8 \times 10^3 \text{ N (Tensile)}$$

The force calculation is shown as $\frac{3240 \times 8 \times 10^3}{1000}$.

From this we get the value of p is equal to 70.8×10^3 so much of Newton which is tensile and hence the stresses which we get and the stresses which we get from this are in the bronze part σ_{br} equal to 29.5 MPa σ_{Al} is equal to 59 MPa and σ_{st} is equal to 118 MPa which will be p divided by respective cross-sectional area.

(Refer Slide Time: 50:29)

IIT Kharagpur

Example Problem - 2

Copper tube — Steel bolt

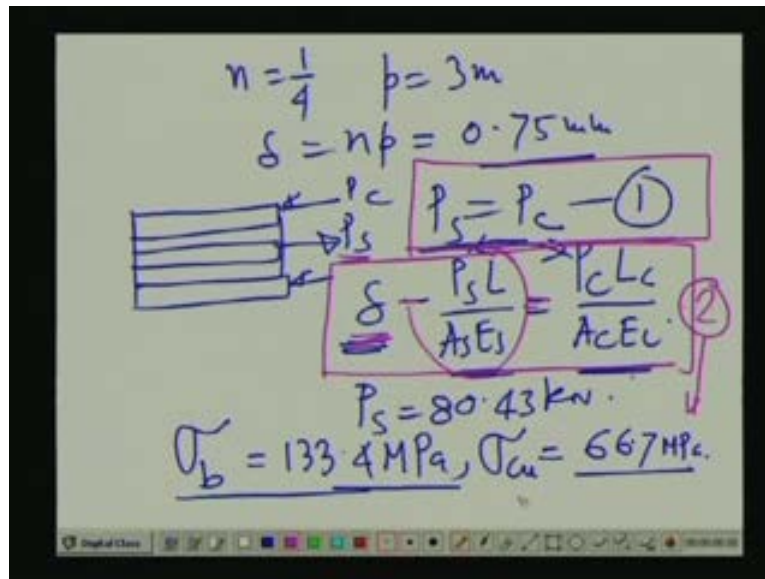

500 mm

- What stresses will be produced in the steel bolt and copper tube? Quarter turn of bolt is applied. Pitch = 3mm; $A_s = 600 \text{ mm}^2$; $A_{cu} = 1200 \text{ mm}^2$; $E_s = 200 \text{ GPa}$; $E_{cu} = 80 \text{ GPa}$

Now let us look into the second problem which will be the stresses that will be produced into this steel. When there is a quarter turn of the bolt there is a nut here and this nut is given a quarter turn then and the pitch of this bolt is 3 mm. This is the threaded part, now area of cross section is given of the copper also is given this the steel bolt and these are the copper tube. Now this is

given a turn and then naturally the copper is under compression, the bolt is tensed so we will have to find out that what the stresses are which will be induced in this assembly because of the turning of the nut.

(Refer Slide Time: 53:20)

Since the turn is 1 by 4th so n is equal to 1 by 4th, pitch is equal to 3 mm so the delta is equal to n into p is equal to 0.75 mm and this is the copper sleeve and this is the steel bolt, the compatibility gives that the compression in the copper sleeve is equal to the tensile pull in the steel bolt. So P_s is equal to P_c this is the equilibrium criteria and the compatibility gives that the deformation is same. The deformation delta minus the deformation of the steel which is $P_s L$ by $A_s E_s$ is equal to $P_c L_c$ by $A_c E_c$, this is the deformation that is being exerted by the nut minus the extension of the steel should be equals to the compression of the copper tube.

From this if we substitute the value of delta which we have already seen here we get another relation between P_s and P_c and also we know that P_s is equal to P_c . From this P_s comes as 80.43 kN and the P_s is equal to P_c . So stress in the bolt σ_b is equal to P_s divided by the cross-sectional area of the bolt which is 600 mm square is equal to 133.4 MPa and the stress in the copper sleeve is equal to this force divided by the cross-sectional area which comes to 66.7 MPa. Therefore these are the stresses that will be induced into the bolt and the sleeve. So here we have the equation of equilibrium which is P_s is equal to P_c and the compatibility equation is that deformation that has been created by the nut minus the strain because of extension of the bolt equal to the strain that is being induced in the sleeve. So this criteria along with this gives us the solution for P_s and P_c .

IIT Kharagpur

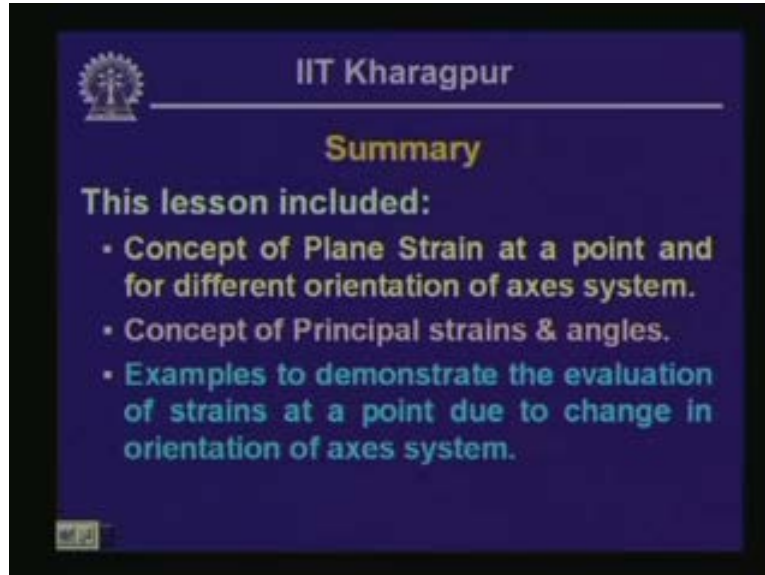

Example Problem - 3

- The state of plane strain at a point in a body is given by $\epsilon_x = 340 \times 10^{-6}$; $\epsilon_y = 110 \times 10^{-6}$ and $\gamma_{xy} = 180 \times 10^{-6}$. Determine the strain components if the axes are oriented at an angle of 30° with reference axes in anticlockwise direction. Also determine the Principal strains.

Digital Class

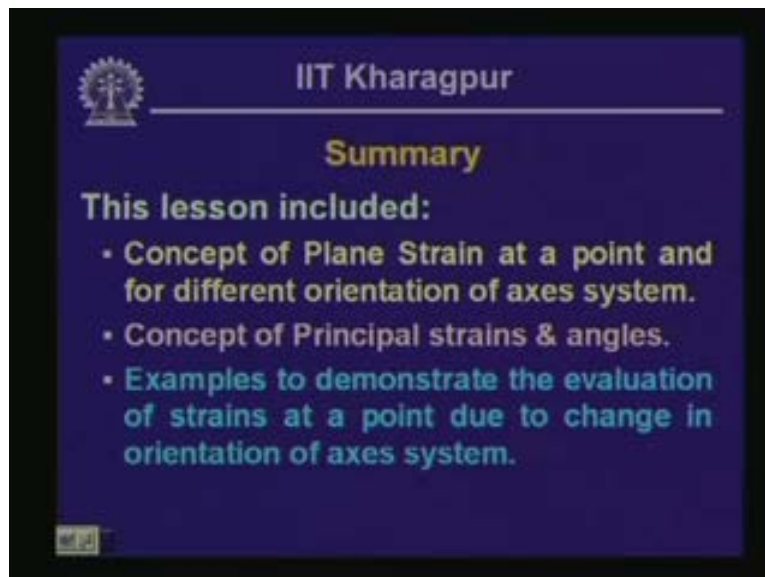

We have another example problem. Later on let us discuss about the state of plane strain at a point in a body given by ϵ_x which is 340×10^{-6} , ϵ_y is equal to 110×10^{-6} and γ_{xy} is 180×10^{-6} . What you need to do is that, determine the strain components if the axes are oriented at an angle of 30° with reference axes in anticlockwise direction and also determine the principal strain. We need to compute it. We have reference axes strain ϵ_x , ϵ_y and with this reference axes the state of axes is oriented at an angle of 30° in an anticlockwise form. So you will have to find out the strain at that particular point which is the state of plane strain. You got to evaluate the strain ϵ_x' , ϵ_y' and $\gamma_{x'y'}$ and also we will have to find out principal strains ϵ_1 and ϵ_2 .

(Refer Slide Time: 54:48)

With reference to rectangular axes system we have to plot plane strain the three different strains as ϵ_x , ϵ_y and γ_{xy} . Now at that particular point for different position of any rectangular axes system which is oriented at an angle of θ with reference to x and y we can compute the values of strain in terms of those ϵ_x , ϵ_y and γ_{xy} and those strains we have termed as plane strain.

(Refer Slide Time: 56:04)

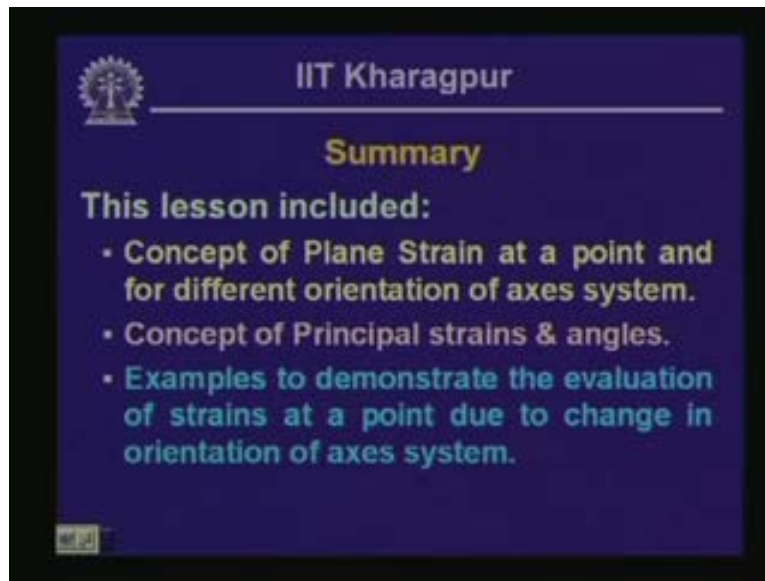

These strains which we evaluate in other reference axes in terms of ϵ_x , ϵ_y and γ_{xy} we call them as transformation equation.

Concept of principle strains and principle angles:

As we did in case of stresses, from the stress we can compute the values of principle strains and principle angles. Also we have solved some examples. I have solved one problem in which we got to compute the value of the strain with reference to the rectangular axes system in axes which is oriented at an angle of 30 degrees with x in anticlockwise form.

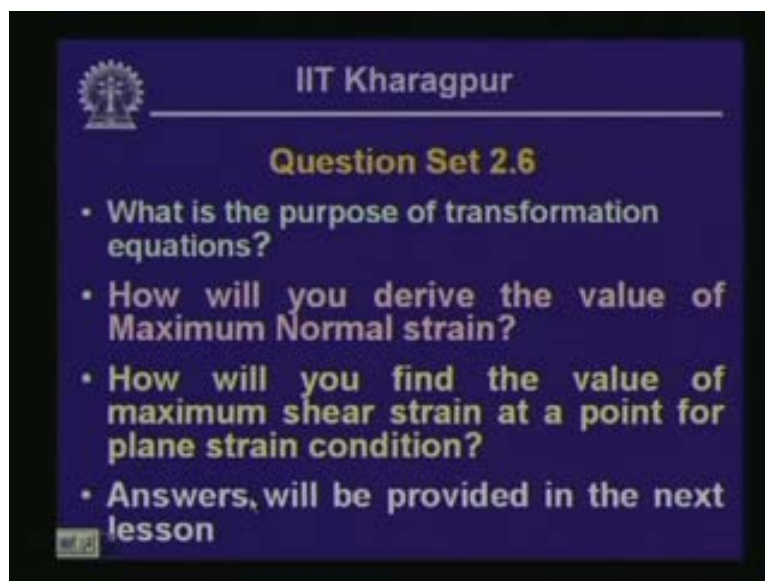

(Refer Slide Time: 56:42)

The slide features the IIT Kharagpur logo in the top left corner. The text is centered and reads: "IIT Kharagpur" followed by a horizontal line, then "Summary" in yellow. Below that, it says "This lesson included:" followed by a bulleted list of three items: "Concept of Plane Strain at a point and for different orientation of axes system.", "Concept of Principal strains & angles.", and "Examples to demonstrate the evaluation of strains at a point due to change in orientation of axes system." A small logo is visible in the bottom left corner of the slide.

Now we know how to compute the stresses with reference to that change of orientation of the axes system.

(Refer Slide Time: 57:43)

The slide features the IIT Kharagpur logo in the top left corner. The text is centered and reads: "IIT Kharagpur" followed by a horizontal line, then "Question Set 2.6" in yellow. Below that, it lists four questions: "What is the purpose of transformation equations?", "How will you derive the value of Maximum Normal strain?", "How will you find the value of maximum shear strain at a point for plane strain condition?", and "Answers, will be provided in the next lesson". A small logo is visible in the bottom left corner of the slide.

These are the questions:

What is the purpose of transformation equations?

From this discussion you will be able to understand why we really need the transformation equation to be derived, what is the need for that etc which you should be able to answer.

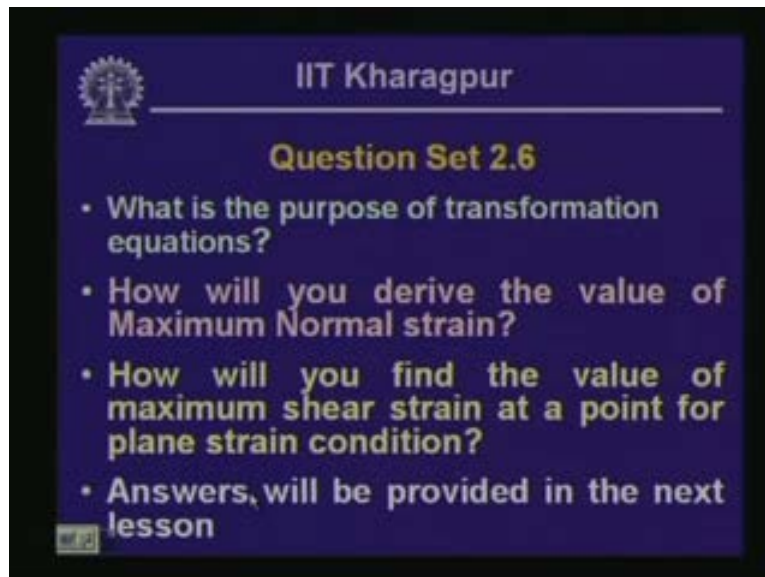

How you will derive the value of maximum normal strain?

You should be familiar with this particular part maximum normal strain with reference to the stresses.

How will you find the value of maximum shear strain at a point called plane strain condition?

This is also in a similar line with the stresses. We have computed the values of maximum and the minimum shear when in a loaded structure at a particular point. We evaluated the stresses and thereby we had computed the principle stresses, we had computed the value of the shearing stress and we had computed maximum and minimum shearing stress exactly in the similar line as we have done here. We have computed the transformation equations, we have computed the principle strain, and we have computed the principle angle. Now we can compute the maximum shearing strain and the angles for the maximum shearing strain in which the maximum and minimum shearing strain will be acting.

(Refer Slide Time: 58:34)

Question:

How will we find out the maximum shearing strain at a point for plane strain condition corresponding to the strains ϵ_x , ϵ_y and γ_{xy} ?
