Analysis of Strain - VII

Welcome to the 7th lesson of module II on the course on Strength of Materials and this module and the lesson is on Analysis of Strain part VII.

(Refer Slide Time: 00:52)

(Refer Slide Time: 01:50)

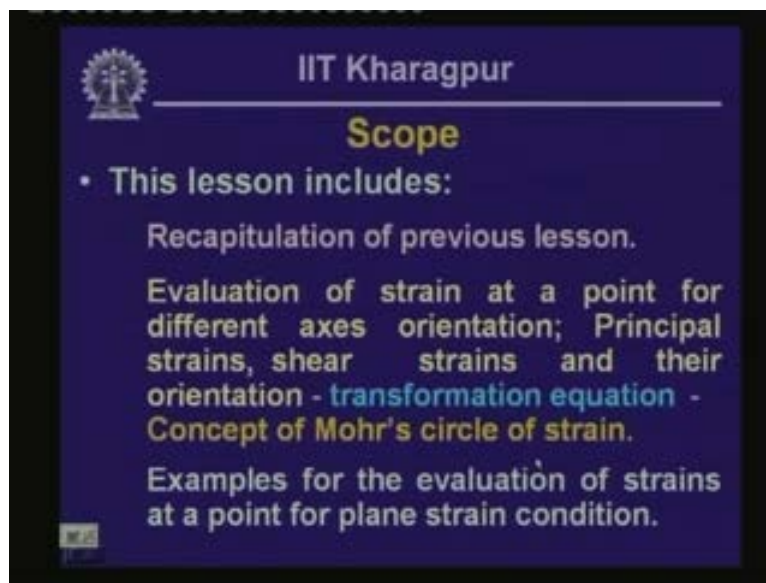

In the previous lesson on Analysis of Strain we had looked into some aspects of evaluating strain at a particular point at a different orientation. If we have axes system oriented

differently from the rectangular axes system then how do you compute the strains with reference to those axes system?

Once this particular lesson is completed one should be able to understand the concept of principal strain and maximum shear strain at a point and their orientations with respect to the rectangular axes system. One should be able to evaluate strains at a point using transformation equations and Mohr's circle of strain.

Let us look into the transformation equations today which we have already discussed. Also as we have looked into, in case of stresses we can evaluate stress at a point using Mohr's circle. We see that we can evaluate strain as well using Mohr's circle of strain.

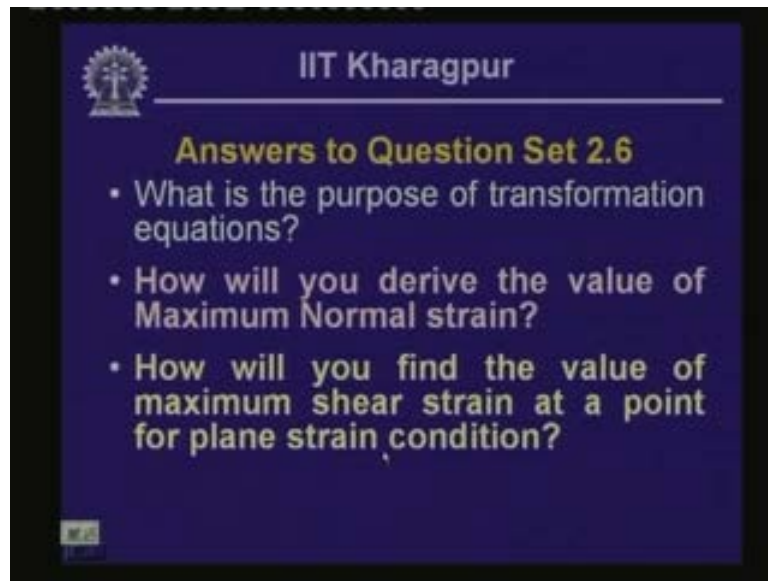

(Refer Slide Time: 03:50)

Hence the scope of this particular lesson includes the recapitulation of previous lesson and we will discuss the answers to the questions that I posed last time which will give you an overview of the previous lesson. Evaluation of strain at a point for different axes orientation; principal strains, shear strains and their orientation In fact with respect to the rectangular axes system as we looked into, the strain at a particular point varies if the axes system differs from the rectangular axes system which is x , y and z .

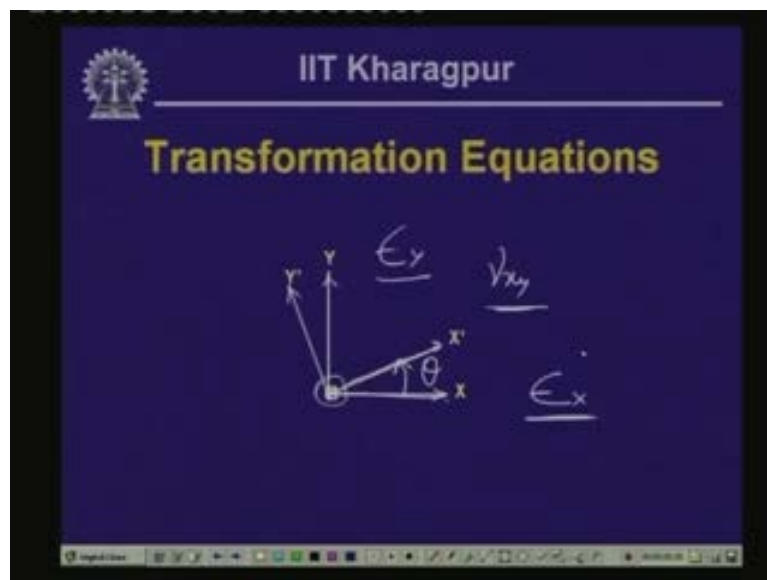

Also, we will be looking into the evaluation of principal strains, the evaluation of shear strains and their orientations with reference to the rectangular axes system through transformation equation which we have dealt with to a certain extent last time and also will introduce the concept of Mohr's circle of strain similar to the line of the Mohr's circle of stress. Then will look into some examples for the evaluation of strains at a point for plane strain condition. That means if we know ϵ_x , ϵ_y , γ_{xy} then how to compute strain at a point if we have different axes orientation and how to compute the principal strains and how to compute the shear strains and their orientations with respect to rectangular axes system.

(Refer Slide Time: 04:11)

Let us look into the answers to the questions which I had posed last time. The first question which was given was what is the purpose of transformation equations? Now that we had derived the transformation equations now we will look into what is the purpose of this particular equation.

(Refer Slide Time: 05:03)

At a particular point if we are interested to evaluate the strains in terms of the strains which are known in the x direction, y direction and shearing strain i.e. ϵ_x , ϵ_y and γ_{xy} . Then in this particular point if we like to evaluate the strain with reference to another axis system which is oriented at an angle of θ with reference to x axis and let us say this is x' and y' axes then what will be the state of strain at this particular point? Will they still be ϵ_x , ϵ_y and γ_{xy} or will they be different?

Through transformation equation we tried to evaluate the strains at that particular point with reference to different axis system which are x prime y prime in this particular case. So the purpose of the transformation equations is to evaluate the strain at different orientations with reference to the rectangular axis system x and y.

The second question was how will you derive the value of maximum normal strain? Please note here that we are going to find out the value of the maximum normal strain. We had computed the value of normal strain at a particular point when the axes system is oriented at an angle of theta with reference to x and y. Now what we need to do is that to first find out the value of the maximum normal strain and the location where that occurs.

(Refer Slide Time: 07:59)

IIT Kharagpur

Transformation Equations

- $\epsilon_{x'} = \epsilon_x \cos^2\theta + \epsilon_y \sin^2\theta + \gamma_{xy} \sin\theta \cos\theta$
- $\epsilon_{x'} = \frac{(\epsilon_x + \epsilon_y)}{2} + \frac{((\epsilon_x - \epsilon_y)\cos 2\theta)}{2} + \frac{(\gamma_{xy} \sin 2\theta)}{2}$
- $\epsilon_{y'} = \epsilon_x \sin^2\theta + \epsilon_y \cos^2\theta - \gamma_{xy} \sin\theta \cos\theta$
- $\epsilon_{y'} = \frac{(\epsilon_x + \epsilon_y)}{2} - \frac{((\epsilon_x - \epsilon_y)\cos 2\theta)}{2} - \frac{(\gamma_{xy} \sin 2\theta)}{2}$
- $\frac{\gamma_{x'y'}}{2} = -\frac{((\epsilon_x - \epsilon_y)\sin 2\theta)}{2} + \frac{(\gamma_{xy} \cos 2\theta)}{2}$

Now the transformation equations we had derived $\epsilon_{x'}$ the normal strain in the x direction is $\epsilon_x \cos^2\theta + \epsilon_y \sin^2\theta + \gamma_{xy} \sin\theta \cos\theta$ where theta is the angle which is oriented in an anticlockwise form with reference to the x axis. And thereby $\epsilon_{x'}$ can be written as $(\epsilon_x + \epsilon_y) / 2 + ((\epsilon_x - \epsilon_y) \cos 2\theta) / 2 + (\gamma_{xy} \sin 2\theta) / 2$. And also if we substitute for theta as theta plus 90 then this gives us the value of $\epsilon_{y'}$ which is $(\epsilon_x + \epsilon_y) / 2 - ((\epsilon_x - \epsilon_y) \cos 2\theta) / 2 - (\gamma_{xy} \sin 2\theta) / 2$.

And the shearing strain with reference to x prime y prime axis which is $\gamma_{x'y'}$ we have written in terms of γ_{xy} by 2 equal to $-\frac{(\epsilon_x - \epsilon_y) \sin 2\theta}{2} + \frac{\gamma_{xy} \cos 2\theta}{2}$. Now let us look into, that if we have to find out the maximum normal strain, now this is the normal strain $\epsilon_{x'}$ which is acting in the x direction. What we need to do now is to find out the value of the maximum normal strain. To do that if we take the derivative of this strain with respect to theta we can get the value of the angle at which the maximum normal strain will be oriented. Let us look into that aspect first.

(Refer Slide Time: 09:47)

$$\epsilon_{x'} = \left(\frac{\epsilon_x + \epsilon_y}{2}\right) + \left(\frac{\epsilon_x - \epsilon_y}{2}\right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$$
$$\frac{d\epsilon_{x'}}{d\theta} = \left(\frac{\epsilon_x - \epsilon_y}{2}\right) (-2 \sin 2\theta) + \frac{\gamma_{xy}}{2} \cdot 2 \cos 2\theta$$
$$0 = -\left(\frac{\epsilon_x - \epsilon_y}{2}\right) \sin 2\theta + \gamma_{xy} \cos 2\theta$$
$$\tan 2\theta_p = \frac{\gamma_{xy}}{\epsilon_x - \epsilon_y}$$

Now $\epsilon_{x'}$ as we have noted down is equal to ϵ_x plus ϵ_y by 2 plus ϵ_x minus ϵ_y by $2 \cos 2\theta$ plus γ_{xy} by $2 \sin 2\theta$. Now if we take the derivative of this with respect to θ this is equal to ϵ_x minus ϵ_y by 2 minus $2 \sin 2\theta$ plus γ_{xy} by $2 \cos 2\theta$ these two gets cancelled. So this is now maximized using the normal strain this is equal to 0 so 0 equal to $\theta \times$ minus ϵ_y by $2 \sin 2\theta$ with minus sign here plus $\gamma_{xy} \cos 2\theta$. Now this gives us the value of $\tan 2\theta$ equal to γ_{xy} by ϵ_x minus ϵ_y so these two gets cancelled, so it is ϵ_x minus ϵ_y $\sin 2\theta$ so $\tan 2\theta$ equal to γ_{xy} by ϵ_x minus ϵ_y .

Now let us call this angle with the suffix p or the maximum normal strain we generally designate as principal strain. As we had done in case of stresses the maximum normal stress and the minimum normal stress are designated as principal stresses but here the strain values the maximum normal strains we call as principal strains and their orientation angles are denoted with θ_p . Now this particular equation has two solutions, one is $2\theta_p$ and $\tan 180$ plus $2\theta_p$ which is also the same value. So we will have two angles; one is θ_p and the other one is 90 plus θ_p in the physical plane.

(Refer Slide Time: 10:32)

$$\epsilon_{x'} = \left(\frac{\epsilon_x + \epsilon_y}{2}\right) + \left(\frac{\epsilon_x - \epsilon_y}{2}\right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$$

$$\frac{d\epsilon_{x'}}{d\theta} = \left(\frac{\epsilon_x - \epsilon_y}{2}\right) (-2 \sin 2\theta) + \frac{\gamma_{xy}}{2} \cdot 2 \cos 2\theta$$

$$0 = -\left(\frac{\epsilon_x - \epsilon_y}{2}\right) \sin 2\theta + \gamma_{xy} \cos 2\theta$$

$$\tan 2\theta_p = \frac{\gamma_{xy}}{\epsilon_x - \epsilon_y} = \frac{2\theta_p}{\tan(180 + 2\theta_p)}$$

(Refer Slide Time: 14:27)

$$\tan 2\theta_p = \frac{\gamma_{xy}}{\epsilon_x - \epsilon_y}$$

$$R = \sqrt{(\epsilon_x - \epsilon_y)^2 + \gamma_{xy}^2}$$

$$\cos 2\theta_p = \frac{\epsilon_x - \epsilon_y}{R}, \quad \sin 2\theta_p = \frac{\gamma_{xy}}{R}$$

$$\epsilon_1 = \frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2}\right) \left(\frac{\epsilon_x - \epsilon_y}{R}\right) + \frac{\gamma_{xy} \gamma_{xy}}{2R}$$

$$= \frac{\epsilon_x + \epsilon_y}{2} + \frac{(\epsilon_x - \epsilon_y)^2 + \gamma_{xy}^2}{2R}$$

$$= \frac{\epsilon_x + \epsilon_y}{2} + \frac{\sqrt{(\epsilon_x - \epsilon_y)^2 + \gamma_{xy}^2}}{2}$$

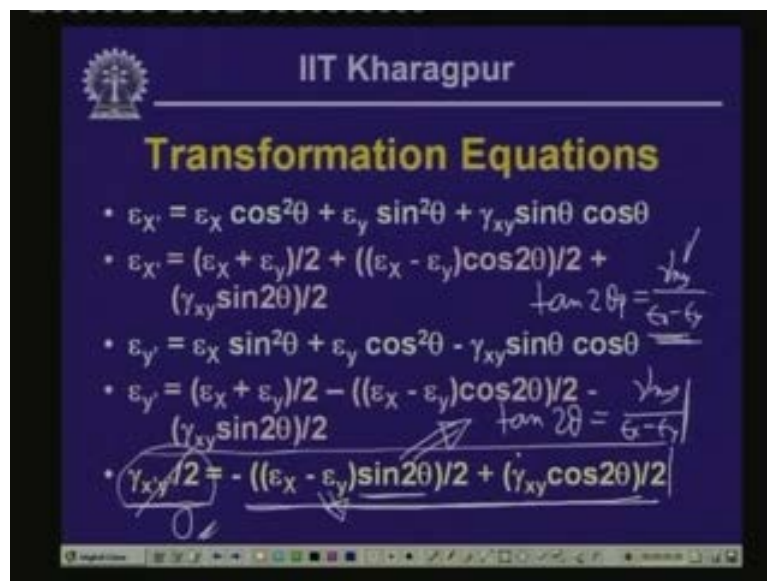

$$= \frac{\epsilon_x + \epsilon_y}{2} + \sqrt{\left(\frac{\epsilon_x - \epsilon_y}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2}$$

So these give us the orientation of the direction along which the normal strain will be maximum. Now if this is the orientation along which normal strain is the maximum then what is the value of the corresponding normal strain which is the maximum normal strain. We have obtained that $\tan 2\theta_p$ equal to γ_{xy} by ϵ_x minus ϵ_y . If this is the angle $2\theta_p$ then this is γ_{xy} and this is ϵ_x minus ϵ_y so let us call this as hypotenuse R so R equal to square root of ϵ_x minus ϵ_y square plus γ_{xy} square. So $\cos 2\theta_p$ equal to ϵ_x minus ϵ_y by r and $\sin 2\theta_p$ equal to γ_{xy} by r . If we substitute the value of $\cos 2\theta_p$ and $\sin 2\theta_p$ in the expression for $\epsilon_{x'}$ that will give us the maximum value of the normal strain so let us call that as ϵ_1 equal to ϵ_x plus ϵ_y by 2 plus ϵ_x minus ϵ_y by 2, in place of $\cos 2\theta_p$ we write ϵ_x minus ϵ_y by r plus γ_{xy} by 2 and in place of $2\theta_p$ we write γ_{xy} by R equal to ϵ_x plus ϵ_y by 2 plus ϵ_x minus

ϵ_y square plus γ_{xy} square by $2R$ and the numerator ϵ_x minus ϵ_y square plus γ_{xy} square equal to R square.

This we write as R square so this R square and this R square cancelled so it becomes R by 2 equal to ϵ_x plus ϵ_y by 2 plus this is R which is $\frac{1}{2}$ square root of ϵ_x minus ϵ_y square plus γ_{xy} square. If we take these two on the inside then this can be written as ϵ_x plus ϵ_y by 2 plus square root of ϵ_x minus ϵ_y by 2 square plus γ_{xy} by 2 square. This is the value of the maximum normal strain acting at that particular point.

(Refer Slide Time: 15:50)

Here if you look into the shearing strain $\gamma_{x' y'}$ is given as this, now we have already looked into the angle at which the maximum normal strain occurs is $\tan(2\theta_p)$ equal to γ_{xy} by ϵ_x minus ϵ_y .

In this particular expression for shearing strain if we substitute for $\gamma_{x' y'}$ equal to 0 this expression leads us to the value of $\tan 2\theta$ equal to γ_{xy} by ϵ_x minus ϵ_y . This expression indicates that if this $\gamma_{x' y'}$ is substituted as 0 then $\tan 2\theta$ equal to γ_{xy} by ϵ_x minus ϵ_y . This indicates that the angle at which the maximum normal strain occur the shearing strain is 0 at that place.

In case of stresses the plane along which the maximum normal stress acts at that particular plane the shearing stress is 0. In similar line here where the orientation at which we get the maximum normal strain which we are calling as principal strain then in that element the shearing strain is 0 where maximum normal strain occurs.

(Refer Slide Time: 17:38)

The slide is from IIT Kharagpur and is titled "Principal angles & Strains". It contains the following text and equations:

- Principal angles may be calculated from:
$$\tan 2\theta_p = \gamma_{xy} / (\epsilon_x - \epsilon_y)$$

Handwritten notes: $2\theta_p \rightarrow \epsilon_1$ (Max) and $(180 + 2\theta_p) \rightarrow \epsilon_2$ (Min)
- Value of Principal strains are:
$$\epsilon_{1,2} = (\epsilon_x + \epsilon_y) / 2 \pm \sqrt{((\epsilon_x - \epsilon_y) / 2)^2 + (\gamma_{xy} / 2)^2}$$

Handwritten notes: "Max. & Min. Normal Strain"

Now we have seen that the $\tan 2\theta_p$ equal to γ_{xy} by ϵ_x minus ϵ_y and corresponding to the angle of $2\theta_p$ we get the value of ϵ_1 with odd ϵ_{\max} we call this as ϵ_{\max} . Now if we substitute as 180 degrees plus $2\theta_p$ as the other angle and substitute for cos and sin we can get the value of ϵ_2 . So the ϵ_1 or ϵ_2 the maximum and the minimum normal strain are given as ϵ_x plus ϵ_y by 2 plus minus, plus is for ϵ_1 and minus is for ϵ_2 as square root of ϵ_x minus ϵ_y by 2 square plus γ_{xy} by 2 square as we have derived just now.

The third question was how you will find the value of maximum shear strain at a point for plane strain condition. Now let us look into this particular answer that how we are going to compute the value of maximum shear strain.

(Refer Slide Time: 19:22)

IIT Kharagpur

Maximum Shear Strain

- For maximum or minimum shear strain:
- $\frac{d\gamma_{x'y'}}{d\theta} = -2\cos 2\theta(\epsilon_x - \epsilon_y)/2 - 2\gamma_{xy} \sin 2\theta/2 = 0$
- $\frac{\gamma_{x'y'}}{2} = -\left(\frac{\epsilon_x - \epsilon_y}{2}\right) \tan 2\theta + \frac{\gamma_{xy}}{2}$
- This gives $\tan 2\theta_s = -\frac{(\epsilon_x - \epsilon_y)}{\gamma_{xy}}$

(Note: The slide also includes a small diagram showing a coordinate system with x and x' axes at an angle theta.)

As we have seen the shearing strain at any orientation which is oriented at an angle of theta with reference to x axis which is our x prime gamma x prime y prime corresponding to that particular direction is $\epsilon_x - \epsilon_y$ by 2 cos 2theta plus γ_{xy} by 2 sin 2theta plus γ_{xy} by 2 cos 2theta.

Now if we take the derivative of that $\gamma_{x'y'}$ by 2 equal to minus $\epsilon_x - \epsilon_y$ by 2 sin 2theta plus γ_{xy} by 2 cos 2theta. Now we take the derivative of this with respect to theta and eventually this gives as $\epsilon_x - \epsilon_y$ by 2 star minus 2 cos 2theta and minus sin 2theta minus 2 γ_{xy} sin 2theta by 2. And if we say this as 0 $d\gamma_{x'y'}$ by $d\theta$ then we get the value of tan 2theta again from this expression which is equal to $\epsilon_x - \epsilon_y$ by γ_{xy} .

In the previous case we evaluated the maximum normal strain and we had the value of angle two theta_p as γ_{xy} by $\epsilon_x - \epsilon_y$ and in this particular case when we are taking the derivative of the shearing strain with respect to theta we are getting the value of the angle which we are calling as the angle for the shear tan 2theta_s equal to $\epsilon_x - \epsilon_y$ by γ_{xy} .

(Refer Slide Time: 20:45)

IIT Kharagpur

Maximum Shear Strain

- For maximum or minimum shear strain:
- $\frac{d\gamma_{xy}/d\theta = -2\cos 2\theta(\epsilon_x - \epsilon_y)/2 - 2\gamma_{xy}\sin 2\theta/2}{= 0}$
- $\frac{\gamma_{xy}}{2} = -\left(\frac{\epsilon_x - \epsilon_y}{2}\right) \frac{\sin 2\theta}{\cos 2\theta}$
- This gives $\tan 2\theta_s = -\frac{(\epsilon_x - \epsilon_y)}{\gamma_{xy}}$
- $\tan 2\theta_s = -\frac{1}{\tan 2\theta_p}$
- $2\theta_s = 90 + 2\theta_p \Rightarrow \theta_s = 45 + \theta_p$

In general we can write $\tan 2\theta_s$ equal to minus 1 by $\tan 2\theta_p$ equal to minus $\cot(2\theta_p)$ and this we can write as $\tan 90 + 2\theta_p$. So $2\theta_s$ equal to $90 + 2\theta_p$. Hence θ_s equal to 45 degrees plus θ_p . This shows that the angle at which the shearing strain is maximum that orientation is 45 degree with respect to the orientation with reference to the principal axes strain. So the direction along which maximum normal strain occurs where we get ϵ_1 which is the maximum ϵ_x if we orient by another 45 degrees the values of maximum and minimum shear strain we get will be corresponding to the axes which we will get.

(Refer Slide Time: 24:37)

IIT Kharagpur

Shear Strain

- Maximum / Minimum shear strain in the xy - plane is given by:
- $\gamma_{max} = \sqrt{\left(\frac{\epsilon_x - \epsilon_y}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2}$
- $\pm \text{sqrt} \left(\left(\frac{\epsilon_x - \epsilon_y}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2 \right)$
- $\frac{\gamma_{xy}}{2} = -\frac{(\epsilon_x - \epsilon_y)}{2} \frac{\sin 2\theta}{\cos 2\theta}$
- $R = \sqrt{\left(\frac{\epsilon_x - \epsilon_y}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2}$
- $\cos 2\theta_s = \frac{\frac{\gamma_{xy}}{2}}{R}$
- $\sin 2\theta_s = -\frac{(\epsilon_x - \epsilon_y)}{R}$

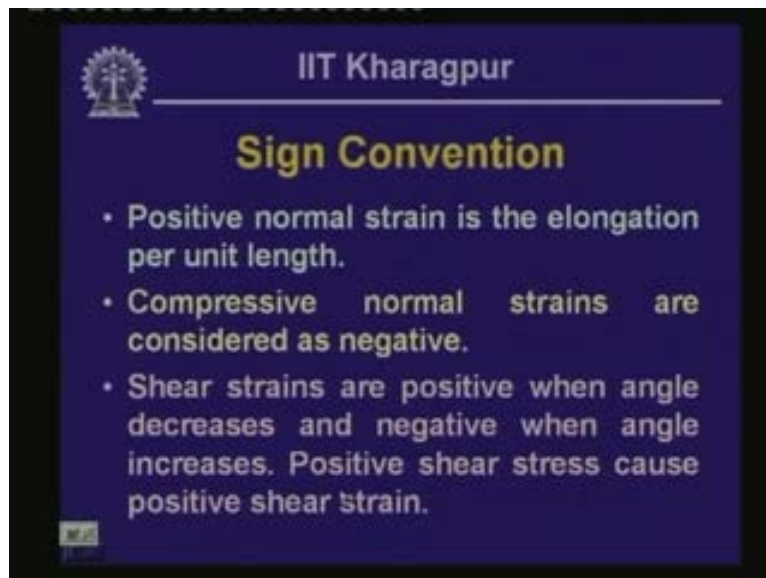

If we take the values of $\tan 2\theta_s$ as we have obtained, now this is the angle $2\theta_s$, this is the γ_{xy} and this is minus ϵ_x minus ϵ_y . So this is at $\tan 2\theta_s$ equal to minus ϵ_x minus ϵ_y by γ_{xy} and the value of R equal to square root of ϵ_x minus ϵ_y square plus γ_{xy} square. Hence the value of $\cos 2\theta_s$ equal to

γ_{xy} by R and $\sin 2\theta_s$ equal to $\frac{\epsilon_x - \epsilon_y}{2R}$. Now if we substitute the values of $\cos 2\theta_s$ and $\sin 2\theta_s$ in the expression for γ which is $\gamma = \frac{\epsilon_x + \epsilon_y}{2} + \frac{\epsilon_x - \epsilon_y}{2} \cos 2\theta + \gamma_{xy} \sin 2\theta$ equal to $\frac{\epsilon_x + \epsilon_y}{2} + \frac{\epsilon_x - \epsilon_y}{2} \cos 2\theta_s + \gamma_{xy} \sin 2\theta_s$.

Now in this particular expression if we substitute for $\cos 2\theta$ and $\sin 2\theta$ in terms of $\frac{\epsilon_x + \epsilon_y}{2R}$ and $\frac{\epsilon_x - \epsilon_y}{2R}$ we get these as $\frac{\epsilon_x + \epsilon_y}{2} + \frac{\epsilon_x - \epsilon_y}{2} \frac{\epsilon_x - \epsilon_y}{2R} + \gamma_{xy} \frac{\epsilon_x - \epsilon_y}{2R}$ and eventually again $\frac{\epsilon_x + \epsilon_y}{2} + \frac{\epsilon_x - \epsilon_y}{2} \frac{\epsilon_x - \epsilon_y}{2R} + \gamma_{xy} \frac{\epsilon_x - \epsilon_y}{2R}$ square plus γ_{xy}^2 is R^2 equal to R^2 and hence the value of γ_{\max} when we are substituting in terms of $\cos 2\theta_s$ and $\sin 2\theta_s$ then the maximum value of γ_{\max} equal to square root of $\frac{\epsilon_x - \epsilon_y}{2}$ square plus γ_{xy}^2 .

Similarly, in the case of the maximum normal strain we had two angles $180^\circ + 2\theta_p$. Here also we have two angles $2\theta_s + 180^\circ + 2\theta_s$ and if we substitute corresponding values we will get the value of minimum shearing strain and the magnitude of the shearing strain maximum and minimum value is equal to $\frac{\epsilon_x - \epsilon_y}{2} + \gamma_{xy}$ square and maximum is plus of this and minimum is minus of this so this is plusminus square root of $\frac{\epsilon_x - \epsilon_y}{2}$ square plus γ_{xy}^2 . This is the value of the maximum and the minimum shearing strain corresponding to the plane strain condition.

(Refer Slide Time: 24:42)

Now, as we have evaluated the strain at a point, if the reference axis is oriented at an angle of θ with reference to the rectangular axis system x and y we have seen how to compute the value of the maximum normal strain which we have called as the principal strain, we have seen how to compute the value of the maximum shearing strain and the orientations of the principal strain and shearing strain through the angles θ_p and θ_s .

As we did in case of stress evaluation at a point we had calculated the values of the maximum normal stress which we called as principal stress, we calculated the maximum shearing stresses and their orientations with reference to the rectangular axis system.

Now as we did in case of stress evaluations we had evaluated at any orientation through transformation equations, also we had evaluated stresses at a point at any orientation through Mohr's circle of stress. In case of strain as so long we have calculated the values at a point at different orientations the normal strains and shearing strains the maximum value of the normal strain the principal strain and the maximum shearing strain through the use of transformation equations. We can find out the strain at any orientation at a particular point using Mohr's circle of strain.

Now we will look into the concept of Mohr's circle of strain. Before we get into that, let us look into the sign conventions of different strain components. As we have seen that positive normal strain is basically the elongation per unit length. When we said that ϵ_x is the strain in the x direction we referred to the extension or the elongation in the x direction. Likewise when we are talking about the positive strain in the y direction it is its elongation in the y direction.

When we are talking about the negative strain both in the x and y direction basically they are under compression. So, positive normal strain is the elongation per unit length and compressive normal strains are considered as negative. In case of shear strains, this is little different than the normal strain. They are positive when the angle decreases and negative when angle increases. Based on this particular definition of positive and negative shears we can say that positive shear stress cause positive shear strain and the vice versa.

(Refer Slide Time: 34:52)

Now this will be probably clearer when you look into the figures. Now in this particular figure if we look into let us say that this is a small element of length dx at a point where the member is undergoing strain. Now this is the extension and if the strain in the direction is ϵ_x we write this as $\epsilon_x dx$ the extension and this is the elongation and we call this is as positive strain.

Again in this particular element this is dx and this is dy . In this particular case the compression of this element is denoted by this dotted line and this is again $\epsilon_x dx$ but it is

gone in the opposite direction or it has compressed. So here in the particular case ϵ_x is negative.

In this particular case here this is again dx and this is dy . Now in the y direction the element is elongated and it has taken this particular position. So this extension is equal to $\epsilon_y dy$ and here since it is elongation we call this ϵ_y as positive. In this particular figure again this element's length is dx and this is dy . Now here this part has come to this particular position wherein again the compression of this element is equal to $\epsilon_y dy$ but since it has undergone compression so ϵ_y here is negative. That is how we define the positive and negative normal strain.

In case of shearing strain as we say that the angle decreases then this was the position x and y and from this x and y position this was the element dx and dy , here this is oriented in this particular form thereby the angle which was 90 degrees before is getting reduced. Hence this particular shearing strain is called as the positive shear strength and here in an anticlockwise direction it is moving in this form and here in a clockwise direction it is moving in this position and this we call as γ_{xy} by 2 and γ_{xy} by 2.

Now if you remember last time when we were computing the values of $\gamma_{x' y'}$ which was the summation of two quantities α and β and α was the orientation of x axis in the position OA and β was the orientation of y axis along OB and the sum of α and β gave us the value of the shearing strain $\gamma_{x' y'}$. Here the position from OA and OB is moving to this position and thereby the angle is decreasing and we call this shearing strain total γ_{xy} by 2 plus γ_{xy} by 2 which is γ_{xy} as the positive shearing strain and this is the position that this particular element is going to take because of the shearing strain.

Now if you remember, we discussed about positive shear. Now if we draw the shearing stress in this particular element, the direction of positive shear stress is this on this phase and on this phase it is downwards, on this phase it is in this direction and on this phase it is in this direction. Now this positive shear as we had taken in case of the construction of the Mohr's circle this upward shear along with this complementary shear causes an anticlockwise rotation and this shear along with the complementary on the other phase causes clockwise rotation. This anticlockwise rotation we had taken as positive and the clockwise one we had taken as negative.

This positive direction of shear tries to deform the element in this direction, this direction of positive direction tries to deform the element in this direction and that is why this is positive strain. In contrast if we look into the strain which is the negative one here the angle between the two axes OX and OY was in 90 degrees and now because of the strain it has increased. This increase is due to shearing strain and this we define as the negative shear strain so this is again γ_{xy} by 2 and this is γ_{xy} by 2.

Please note that in the previous case this moment was in the anticlockwise direction but in this particular figure it is in the clockwise direction and here it was in a clockwise direction and here it is in an anticlockwise direction. So anticlockwise movement in Mohr's circle we will consider as positive as before and clockwise direction we will consider as negative as before. This is the configuration which shows that this particular element which was of length dx and dy in the initial stage undergoes deformation in the x direction as given here, and it undergoes deformation in the y direction as given here and also it has shearing strain. So the

final position after undergoing the ϵ_x , ϵ_y and γ_{xy} this is the position that it is going to take. So this particular configuration corresponds to ϵ_x , ϵ_y , γ_{xy} where all are positive.

In this particular figure again if we look into this particular element which is originally again of length dx and dy it undergoes strain but in the opposite direction or it gets compressed. So this is the negative ϵ_x , dx and again here in this particular direction this is the deformation it gets compressed which is $\epsilon_y dy$ and it has a negative shearing strain and because of that the angle increases and when we combine all three strains it takes the shape in this particular form. So this particular configuration is corresponding to ϵ_x , ϵ_y , γ_{xy} where all three quantities are negative. This is the sign convention which we follow and we will be following this convention while plotting the Mohr's circle for the strain. Exactly in the similar line we did in case of stress evaluation we will be computing the strain identically using the Mohr's circle of strain.

(Refer Slide Time: 45:40)

Now here let us say we have strain at a point or this is a small element where the lanes are dx and dy and it has undergone strain ϵ_x , ϵ_y and γ_{xy} and from this configuration you can make out that all quantities are positive; ϵ_x is positive, ϵ_y is positive and γ_{xy} is positive. So if we take these quantities we can compare our relationship with the stresses and in case of stresses at any orientation x prime, it was written as a function of σ_x , σ_y and τ_{xy} .

Now here in contrast to this the normal strain ϵ_{xprime} we are writing in terms of ϵ_x , ϵ_y and γ_{xy} by 2. If you look into the expression for ϵ_{xprime} and σ_{xprime} we will find σ_{xprime} equal to σ_x plus σ_y by 2 plus σ_x minus σ_y by 2 cos 2theta plus τ_{xy} sin 2theta. In case of θ_{xprime} we have θ_{xprime} equal to θ_x plus θ_y by 2 plus ϵ_x minus ϵ_y by 2 cos 2theta plus γ_{xy} by 2 sin 2theta. So in place of τ_{xy} we have γ_{xy} by 2, in place of σ_x we have ϵ_x and in place of σ_y we have ϵ_y , otherwise the expression is identical.

Now let us find out how you compute the strain at any orientation with reference to this x and y at a particular point. If we know the strain at a particular point which is given by ϵ_x , ϵ_y and γ_{xy} we are interested to find out strain at that point which is at any orientation at an angle of θ in an anticlockwise form with respect to x so we need to find out ϵ_θ and γ_θ also in that orientation in θ .

Last time in the x axes for stresses we had written down in σ but here we write this strain for ϵ and the y axis instead of τ we write this as $\gamma/2$ axis and this is the origin. From here if we plot the value of ϵ_x and $\gamma_{xy}/2$ then we get one point in this plane which we call as Mohr's plane, also ϵ_y and $\gamma_{xy}/2$.

If you remember that $\gamma_{xy}/2$ when we were looking into the sign convention from x it is oriented at an angle of $\gamma_{xy}/2$ in the anticlockwise form which we are calling as positive and in the y direction it is oriented again by $\gamma_{xy}/2$ in the clockwise direction which is the opposite to this. If we have plotted γ_{xy} in this particular position, now here we take ϵ_y and $\gamma_{xy}/2$. So this is the distance which is ϵ_y and this is $\gamma_{xy}/2$ and this point is at a distance of ϵ_x from origin and this is $\gamma_{xy}/2$. Now if we join these two points and when they cross the ϵ axis then it denotes the centre of the circle and this line is the diameter of the Mohr's circle.

If we look into this particular triangle and this particular triangle now this is equals to this, this is equals to this and this is equals to this so the distance from here to here this particular distance is divided equally by this particular point. From O to A this distance is ϵ_x , from O to B the distance is ϵ_y so the distance AB equal to $\epsilon_x - \epsilon_y$ and the central point from O you call this as O prime so O prime A or O prime B, O prime A equal to O prime B equal to $\epsilon_x - \epsilon_y$ by 2.

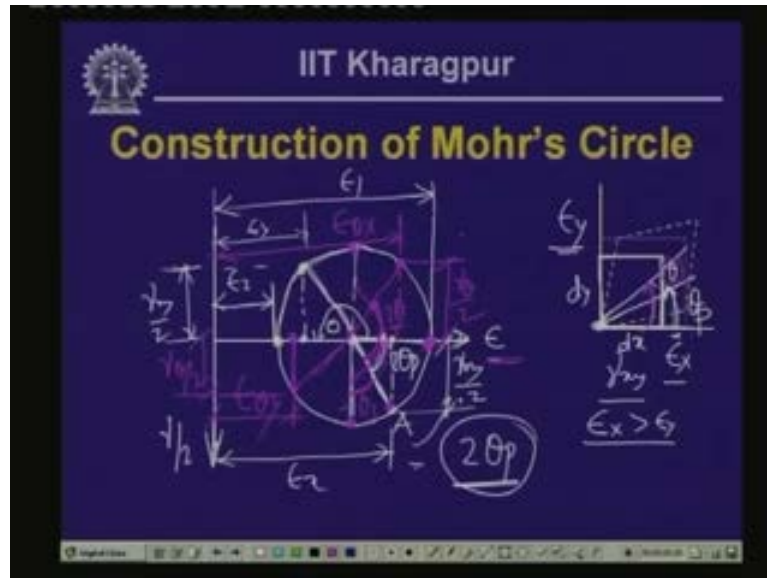

Hence the distance of the centre from the origin, this particular distance is equal to OA minus AO prime the distance OO prime equal to OA minus AO prime. Now OA equal to ϵ_x , so this is equal to $\epsilon_x - \text{AO prime}$ equal to $\epsilon_x - \epsilon_y$ by 2 so this minus $\epsilon_x - \epsilon_y$ by 2 gives the value of $\epsilon_x + \epsilon_y$ by 2. So the distance from the origin to the centre is $\epsilon_x + \epsilon_y$ by 2.

Now if we look into this particular circle, if we take this O prime as the centre and OC as the radius and if we plot a circle eventually we get the circle which we call as the Mohr's circle for strain wherein the axis in the x direction corresponds ϵ and the axis in the y direction corresponds to $\gamma/2$. This is the point which represents the value of the maximum normal strain and this we designate as ϵ_1 . This is the value of the minimum normal strain and this we designate as ϵ_2 , also this is the value which gives us the maximum value of the shearing strain which is equal to the radius of this particular circle.

So, if we know ϵ_x , ϵ_y and γ_{xy} then we can compute the value of ϵ_1 then compute the value of the ϵ_2 and the shearing strain. Now from this you can make out the value of ϵ_1 which will be equal to the distance OO prime plus the radius. From this particular diagram O prime A and C from this particular triangle CA prime equal to $\gamma_{xy}/2$ O prime A equal to $\epsilon_x - \epsilon_y$ by 2 this distance is $\epsilon_x - \epsilon_y$ by 2 so the distance CO prime which is the radius is equal to square root of $\epsilon_x - \epsilon_y$ by 2 square plus $\gamma_{xy}/2$ square. So, the value ϵ_1 equal to OO prime which is $\epsilon_x + \epsilon_y$ by 2 plus square root of $\epsilon_x - \epsilon_y$ by 2 square plus $\gamma_{xy}/2$ square. So this gives us the value of ϵ_1 which we have

seen already through transformation equations and ϵ_2 will be ϵ_0 prime minus the value of the radius. So once we substitute this as minus we will get the value of ϵ_2 and this is the radius which is equal to the plus and minus that gives us the value of the shearing strain. So using Mohr's circle of strain again we can compute the values of the principal strains ϵ_1 , ϵ_2 and the maximum value of the shearing strain.

(Refer Slide Time: 45:40)

Let us look into how to plot the Mohr's circle of strain if we know the normal strain components ϵ_x , ϵ_y and γ_{xy} . For this particular element at a point we have the values of this element as dx and dy and the strains in the x direction as ϵ_x , in the y direction as ϵ_y and the shearing strain as γ_{xy} . Now if we know these components our job will be evaluate the strains at this particular point the maximum normal strains, the maximum shearing strains and their orientations.

For example, if we have a set of rectangular axis which is oriented at an angle of θ with reference to x and y axes then what are the values of the strain corresponding to those orientations can also be evaluated using the Mohr's circle. Now let us look into that if we know the value of ϵ_x , ϵ_y and γ_{xy} at a particular point in a plane strain condition then how we can extract the other information using Mohr's circle of strain.

As we discussed in case of stresses regarding the direction of the axis, remember that you said this is the positive x direction in which we call this as ϵ . Now in the γ by 2 we put the y in the downward direction as positive, the reason behind this was that if we are interested to evaluate the strains at a particular direction which is oriented at an angle of θ in the anticlockwise direction then we can keep the same orientation of angle anticlockwise in the Mohr's plane and to make this compatibility we consider the direction of γ in the downward direction.

If we consider the γ positive in the upward direction then this orientation of anticlockwise in the physical plane will be clockwise in case of the Mohr's plane. Now to keep the clarity between the physical one and the Mohr's plane we keep the axis direction as positive for ϵ on the right hand side and γ by 2 in the downward y direction. Now

assuming that the normal strain ϵ_x is greater than the normal strain ϵ_y we know ϵ_x , ϵ_y and γ_{xy} so we choose a point say ϵ_x and $\gamma/2$ and this is a point on the Mohr's plane.

Another point we get corresponding to a value of ϵ_y and correspondingly the $\gamma/2$ so this distance is ϵ_x and this is $\gamma_{xy}/2$, this is ϵ_y and this is $\gamma_{xy}/2$. If we join these two points it crosses the ϵ axis at this particular point and this is the diameter of the Mohr's circle and this is the centre of the Mohr's circle. Now with this if we plot the circle we get the Mohr's circle of strain. Now corresponding to this particular circle the value of the maximum normal strain is this which we have denoted as ϵ_1 , the minimum normal strain is this which we have denoted as ϵ_2 and the value of the maximum shearing strain positive shear strain is this and value of negative shear strain maximum or the minimum shear strain is this.

Now this is the point which denotes the maximum normal strain ϵ_1 and this particular point is oriented at an angle of $2\theta_p$ with reference to this, now this is our reference line where ϵ_x , γ_{xy} occurs so from this particular reference line let us call this as OA so if we orient by an angle of $2\theta_p$ then we get the position for the maximum normal strain. Then if we orient from the position of the maximum normal strain by 180 degrees then we get the position for minimum normal strain. These are the values of ϵ_1 and ϵ_2 and this is the angle which gives us the value of maximum normal strain which is $2\theta_p$ in the Mohr's plane and in the physical plane it will be θ_p .

Now if we are interested to compute the strain at any orientation which is at an angle of θ with reference to x then we plot an angle 2θ from this particular reference line and if we go in an anticlockwise direction, if this is the line which represents 2θ and this particular point gives us the value of a corresponding normal and the shearing strain. So this is value of ϵ the normal strain at θ and this is the corresponding value of $\gamma/2$. And if we go in the opposite direction diametrically opposite point this will give the value of ϵ_y , ϵ_θ or ϵ_{θ_x} and ϵ_{θ_y} and correspondingly this value is $\gamma_\theta/2$.

In this particular plane this θ is oriented at an anticlockwise fashion with θ and here also in the Mohr's plane we go in the anticlockwise direction by 2θ to locate that particular orientation in the Mohr's plane and that is why we consider the direction of ϵ axis and γ axis in this form so that this compatibility between the orientation is maintained. Also, if you note that this is the orientation along which the maximum and the minimum shear strains are occurring so they are with reference to this particular reference plane which will be at an angle, this is minus θ_s and from here again if we orient by 180 degrees we will get this.

Now from θ_p this is the position of the maximum normal strain and this is the position of the maximum shearing strain and these two make an angle of 90 degrees in the Mohr's plane and hence these two directions make an angle of 45 degrees in the physical plane and that we have seen through the transformation equations. So what you observe here is that the state of transformation equations as we have derived for evaluating strain components at any orientation with reference to the rectangular axis system xy corresponding to the plane strain condition ϵ_x , ϵ_y and γ_{xy} we can achieve similar results through this Mohr's circle of strain as we have observed in case of the Mohr's circle of stresses before.

Having looked into this let us look into the problem example. If we know the state of strain at a particular point then how do you compute the values of the other strains at a particular angle or the principal strain?

Now the state of plane strain at a point in a body is given by ϵ_x as positive, ϵ_y as this which is positive and γ_{xy} also as positive. Now determine the strain components if the axes are oriented at an angle of 30 degrees with reference axis in anticlockwise direction and also determine the principal strains.

(Refer Slide Time: 56:55)

$$\begin{aligned} \epsilon_x &= 340 \times 10^{-6} & \epsilon_y &= 110 \times 10^{-6} & \gamma_{xy} &= 180 \times 10^{-6} \\ \epsilon_{x'} &= \frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta \\ &= \frac{225 \times 10^{-6}}{2} + \frac{115 \times 10^{-6}}{2} \times \frac{1}{2} + \frac{90 \times 10^{-6} \times \sqrt{3}}{2} \\ &= 360.44 \times 10^{-6} \\ \epsilon_{y'} &= \frac{\epsilon_x + \epsilon_y}{2} - \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \cos 2\theta - \frac{\gamma_{xy}}{2} \sin 2\theta \\ &= 89.36 \times 10^{-6} \\ \epsilon_{x'} + \epsilon_{y'} &= 450 \times 10^{-6} = \epsilon_x + \epsilon_y \end{aligned}$$

If we like to compute the values corresponding to the given values we have ϵ_x equal to 340 into 10 to the power minus 6 we have ϵ_y equal to 110 into 10 to the power minus 6 and we have γ_{xy} equal to 180 into 10 to the power minus 6. Now from the transformation equations we know $\epsilon_{x'}$ which is 30 degrees in this particular case is equal to ϵ_x plus ϵ_y by 2 plus $(\epsilon_x$ minus ϵ_y by 2) cos 2theta plus γ_{xy} by 2 sin 2theta.

Now theta equal to 30 degrees so 2theta equal to 60 degrees so if we substitute these values ϵ_x equal to 340, ϵ_y equal to 110 so this gives us a value of 225 into 10 to the power minus 6 plus 115 into 10 to the power minus 6 and cos 60 is 1/2 plus γ_{xy} by 2 equal to 90 into 10 to the power minus 6 and sin 60 is square root of 3 by 2 and this if you compute it comes as 360.44 into 10 to the power minus 6. So this is the value of $\epsilon_{x'}$ which is oriented at 30 degrees with reference to the x direction.

Corresponding $\epsilon_{y'}$ prime equal to ϵ_x plus ϵ_y by 2 minus ϵ_x minus ϵ_y by 2 cos 2theta minus γ_{xy} by 2 sin 2theta and if we substitute these values it will be 89.36 into 10 to the power minus 6. So, if we add the values of $\epsilon_{x'}$ prime plus $\epsilon_{y'}$ prime this will eventually be approximately equal to 450, it should ideally be 450 into 10 to the power minus 6 equal to ϵ_x plus ϵ_y .

(Refer Slide Time: 58:37)

$$\frac{\gamma_{x'y'}}{2} = - \left(\frac{\epsilon_x - \epsilon_y}{2} \right) \sin 2\theta + \frac{\gamma_{xy}}{2} \cos 2\theta$$

$$= -54.6 \times 10^{-6}$$

$$\gamma_{x'y'} = -109.2 \times 10^{-6}$$

$\epsilon_x \rightarrow +ve$
 $\epsilon_y \rightarrow +ve$
 $\gamma_{xy} \rightarrow -ve$

Now the value of $\gamma_{x'y'}$ by 2 equal to minus ϵ_x minus ϵ_y by 2 $\sin 2\theta$ plus γ_{xy} by 2 $\cos 2\theta$ equal to minus 54.6 into 10 to the power minus 6 if we substitute the values which gives us the value of $\gamma_{x'y'}$ as twice of this equal to 109.2 into 10 to the power minus 6 and this is negative. So initially we had the element which is in this form and we had a strain which is positive in the x direction, we had a strain which is positive in the y direction so this is the positive strain and then ϵ_x also is positive which means the angle is reducing which is in this form. This is the position of the element and in this particular case when we are computing the strain at 30 degrees we have $\epsilon_{x'}$ as positive we have $\epsilon_{y'}$ as positive we have $\gamma_{x'y'}$ as negative and hence if we plot that you can get the configuration corresponding to that particular element.

IIT Kharagpur

Example Problem - 1

- The state of plane strain at a point in a body is given by $\epsilon_x = 340 \times 10^{-6}$; $\epsilon_y = 110 \times 10^{-6}$ and $\gamma_{xy} = 180 \times 10^{-6}$. Determine the strain components if the axes are oriented at an angle of 30° with reference axes in anticlockwise direction. Also determine the Principal strains.

(Refer Slide Time: 58:50)

IIT Kharagpur

Example Problem - 2

- Solve the Example Problem-1 using Mohr's circle of strain. Also, compute Principal strain direction and maximum shear strain.

The next problem is that solve the same problem as we have given in one. But using Mohr's circle of strain compute the principal strain direction and maximum shear strain.

(Refer Slide Time: 59:03)

IIT Kharagpur

Example Problem - 3

- An element of material in plane strain is subjected to strains $\epsilon_x = 480 \times 10^{-6}$; $\epsilon_y = 70 \times 10^{-6}$ and $\gamma_{xy} = 420 \times 10^{-6}$. Evaluate (a) the strains for an element oriented at an angle of 75° with x-axis in anticlockwise direction; (b) the principal strains and (c) maximum shear strain; using Mohr's circle.

The next example is that an element of material in plane strain is subjected to strains of these. We got to evaluate the principal strain and the shear strains and also strain at an angle of 75 degrees.

(Refer Slide Time: 59:13)

IIT Kharagpur

Example Problem - 4

- The strains at a point for an element of material in plane strain are $\epsilon_x = 120 \times 10^{-6}$, $\epsilon_y = -450 \times 10^{-6}$ and $\gamma_{xy} = -360 \times 10^{-6}$. Determine the principal strains and maximum shear strain. Use Mohr's circle of strain.

The fourth problem is that the strain at a point for an element is given by these values. We will have to determine the principal strain and maximum shear strain using Mohr's circle of strain.

(Refer Slide Time: 59:32)

IIT Kharagpur

Summary

This lesson included:

- Concept of Plane Strain at a point and for different orientation of axes system.
- Concept of Principal strains, shear strains and their orientation using transformation equation & Mohr's circle.
- Examples to evaluate strains at a point using transformation equation & Mohr's circle.

This particular lesson included the concept of Plane Strain at a point and for different orientation of axis system, concept of principal strains, shear strains and their orientations using transformation equation and Mohr's circle and examples to evaluate strains at a point using transformation equations and Mohr's circle.

Question Set 2.7

- What is the value of shear strain where Normal strain is maximum?
- What is the value of Normal strain where Shear strain is maximum?
- What is the relationship between the orientation of maximum shear strain to the orientation of maximum Normal strain?
- Answers will be provided in the next lesson

Questions:

What is the value of the shear strain where normal strain is at maximum?

What is the value of normal strain where shear is at maximum?

What is the relationship between the orientation maximum shear strain to the orientation of maximum normal strain.
