**Lecture # 14**  
**Analysis of Strain - VIII**

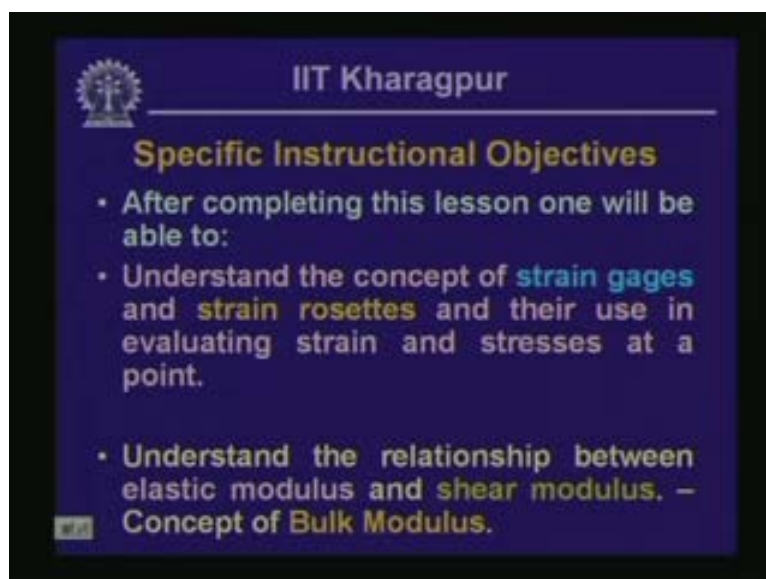

This is the 8 lesson of module 2 which is on Analysis of Strain. We have already discussed quite a few aspects of analysis of strain.

(Refer Slide Time: 01:04)

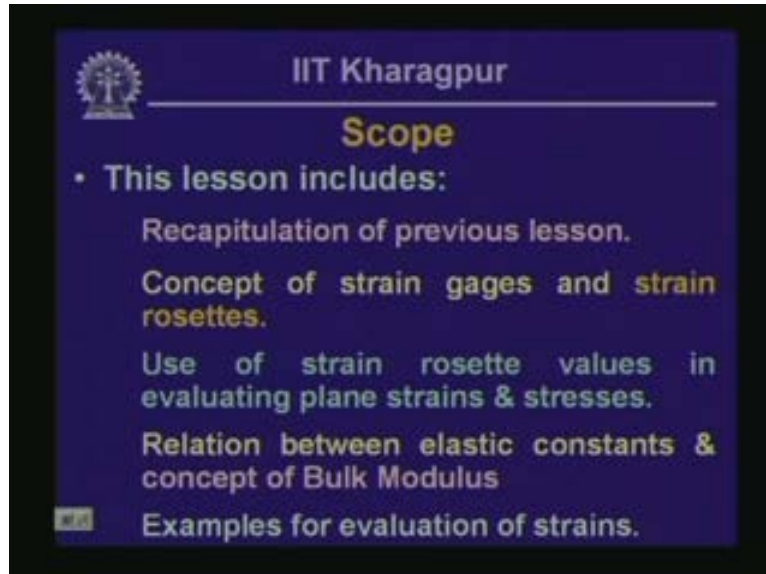

Today we are going to discuss some more aspects of analysis of strain. It is expected that once this particular lesson is completed one should be able to understand the concept of strain gages and strain rosettes and their uses in evaluating strain and stresses at a point.

(Refer Slide Time: 01:37)

One should be able to understand the relationship between elastic modulus and shear modulus, how we relate the elastic modulus to the shear modulus and then consequently the concept of bulk modulus.

(Refer Slide Time: 02:30)

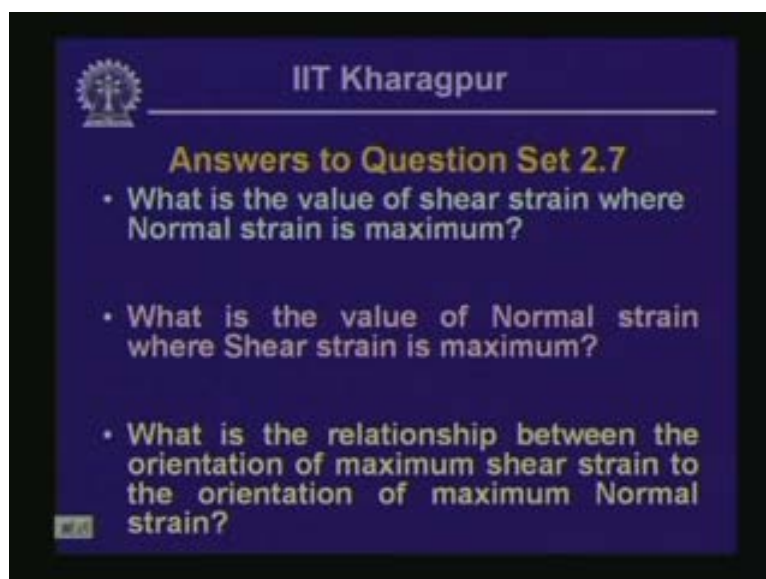

IIT Kharagpur

### Scope

- This lesson includes:
  - Recapitulation of previous lesson.
  - Concept of strain gages and strain rosettes.
  - Use of strain rosette values in evaluating plane strains & stresses.
  - Relation between elastic constants & concept of Bulk Modulus
  - Examples for evaluation of strains.

As the scope of this particular lesson includes the recapitulation of previous lesson we will be answering the questions posed last time. Then concept of strain gages and strain rosettes, use of strain rosette values in evaluating plane strains and stresses will be discussed. We will also discuss how the rosette dilutes the strains which we evaluate or measure through the use of strain rosette and how they are used to compute the values of strains and stresses at a point. Then the relation between elastic constants and then the concept of bulk modulus will be dealt, and we will be solving few examples for evaluation of strains at a point from the given information.

IIT Kharagpur

### Answers to Question Set 2.7

- What is the value of shear strain where Normal strain is maximum?
- What is the value of Normal strain where Shear strain is maximum?
- What is the relationship between the orientation of maximum shear strain to the orientation of maximum Normal strain?

Let us look into the answers of the questions which we posed last time. The first question is what is the value of shear strain where normal strain is at maximum? Probably the first and second questions can be discussed together. What is the value of normal strain where shear strain is at maximum?

(Refer Slide Time: 2:57)

Let us discuss these two questions through the Mohr circle of strain. If you remember last time we had discussed that we can plot the Mohr circle for evaluating strain at a point.

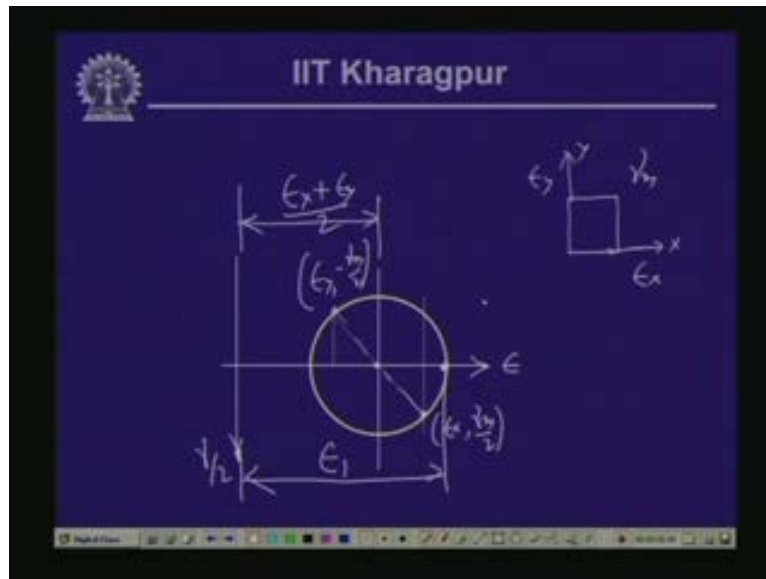

(Refer Slide Time: 3:37)

Now if we have an element which is subjected to strain let us say this is reference x axis and this is y axis, the strain is  $\epsilon_x$ ,  $\epsilon_y$  and the shearing strain is  $\gamma_{xy}$ , now we can plot them in the Mohr circle and this is the point this being the positive strain axis and this is the positive gamma by 2 axis, this particular point represent the positive  $\epsilon_x$  and

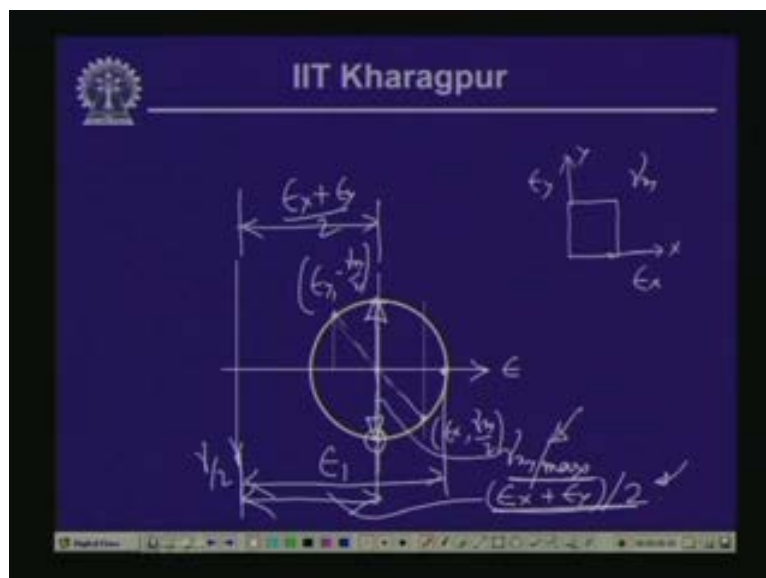

$\gamma_{xy}$  by 2 and this particular point which is diametrically opposite to this particular point represent  $\epsilon_y$  and minus  $\gamma_{xy}$  by 2.

(Refer Slide Time: 4:38)

This is the center of the Mohr circle which is at a distance of  $\epsilon_x + \epsilon_y$  by 2 and this particular point gives us the maximum normal strain which we normally denote as  $\epsilon_1$  the maximum principal strain. And as you can absorb from this particular point and from this diagram, at this point the value of shearing strain is 0. So along the axis where the principal strain or the normal strain is the maximum the value of the shear strain is 0.

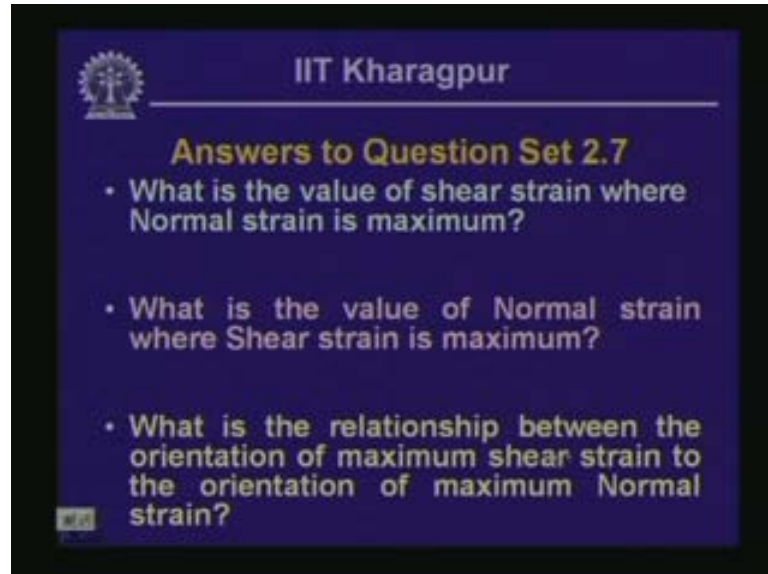

(Refer Slide Time: 5:37)

Consequently if you look into the Mohr circle the maximum value of the strains are at this particular point and at this particular point. This is the maximum positive shear strain and this is the minimum because magnitude-wise they are same but only it is negative. This is  $\gamma_{xy}$  maximum. The point where the shear strain is the maximum the corresponding

normal strain is equal to this and this normal strain is equal to  $\epsilon_x$  plus  $\epsilon_y$  by 2. Therefore along the axis where the shear strain is maximum the corresponding normal strain is  $\epsilon_x$  plus  $\epsilon_y$  by 2. This answers the first two questions.

(Refer Slide Time: 5:54)

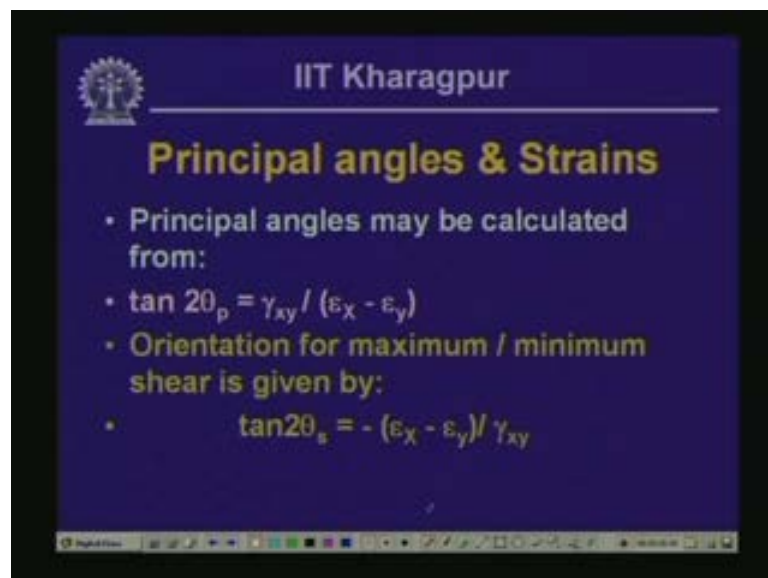

IIT Kharagpur

### Answers to Question Set 2.7

- What is the value of shear strain where Normal strain is maximum?
- What is the value of Normal strain where Shear strain is maximum?
- What is the relationship between the orientation of maximum shear strain to the orientation of maximum Normal strain?

The third question is what is the relationship between the orientations of maximum shear strain to the orientation of maximum normal strain?

(Refer Slide Time: 6:13)

IIT Kharagpur

### Principal angles & Strains

- Principal angles may be calculated from:
- $\tan 2\theta_p = \gamma_{xy} / (\epsilon_x - \epsilon_y)$
- Orientation for maximum / minimum shear is given by:
- $\tan 2\theta_s = - (\epsilon_x - \epsilon_y) / \gamma_{xy}$

Last time we discussed this aspect. The principal angle  $2\theta_p$  for the maximum principal strain can be located using the expression  $\gamma_{xy}$  by  $(\epsilon_x - \epsilon_y)$ .

(Refer Slide Time: 7:13)

IIT Kharagpur

### Principal angles & Strains

- Principal angles may be calculated from:
- $\tan 2\theta_p = \frac{\gamma_{xy}}{\epsilon_x - \epsilon_y}$
- Orientation for maximum / minimum shear is given by:
- $\tan 2\theta_s = - \frac{(\epsilon_x - \epsilon_y)}{\gamma_{xy}}$

In the Mohr circle if we try to locate the principal plane, this is the position of the maximum normal strain and if this is the reference plane or reference point where strain is  $\epsilon_x$  and  $\gamma_{xy}$  by 2 from this particular orientation which is along the x direction if we move anticlockwise by  $2\theta_p$  we get the point of maximum strain. In the physical space if we move in anticlockwise form by an angle of  $\theta_p$  this gives the direction of the principal strain  $\epsilon_1$  and the expression for measuring this angle  $\theta_p$  is  $\tan 2\theta_p$  is equal to  $\gamma_{xy}$  by  $(\epsilon_x - \epsilon_y)$ . Consequently we had seen that the expression for evaluating the angle for maximum shear strain which is  $\tan 2\theta_s$  is equal to  $\epsilon_x - \epsilon_y$  by  $\gamma_{xy}$ .

(Refer Slide Time: 8:25)

IIT Kharagpur

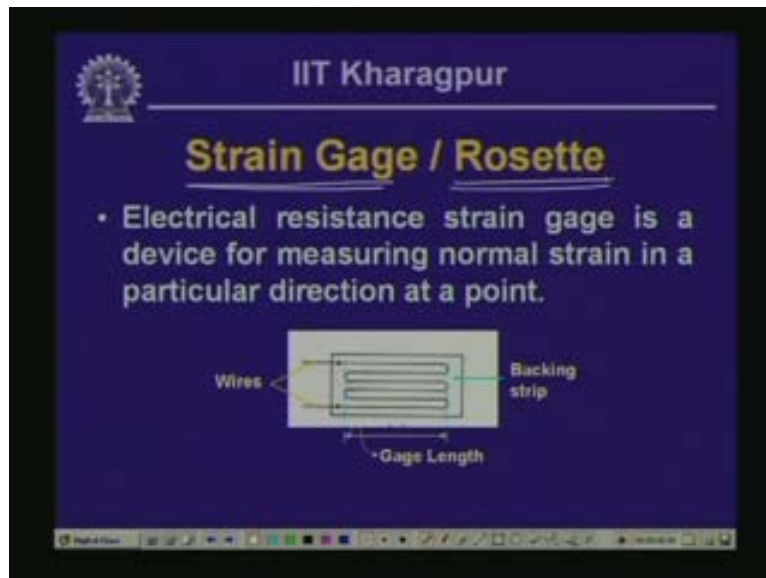

### Principal angles & Strains

- Principal angles may be calculated from:
- $\tan 2\theta_p = \frac{\gamma_{xy}}{\epsilon_x - \epsilon_y}$
- Orientation for maximum / minimum shear is given by:
- $\tan 2\theta_s = - \frac{(\epsilon_x - \epsilon_y)}{\gamma_{xy}} = - \frac{1}{\tan 2\theta_p} = -\cot 2\theta_p = \tan (90 + 2\theta_p)$
- $2\theta_s = 90 + 2\theta_p$

Now this particular value can be written as  $\tan 2\theta_p$  or this is nothing but equals to  $\tan 2\theta_p$ . We can write this as  $\tan (90 \text{ degrees} + 2\theta_p)$  hence  $2\theta_s$  is equal to  $90 + 2\theta_p$  and consequently the solution for this can be  $90 + \theta_p$  angle and  $180$

degrees plus theta will be another angle. So the relationship between the orientation of shear strain which is  $\theta_s$  is equal to 45 degrees plus  $\theta_p$ . That means if we know the direction of the principal strain from that if we orient by 45 degrees we can get the direction for the maximum shear strain. This is the relationship between the orientations of shear strain to the orientation of principal strain direction. These two directions are interrelated and they are at 45 degrees apart in the physical plane which is at 90 degrees apart in the Mohr circle of strain.

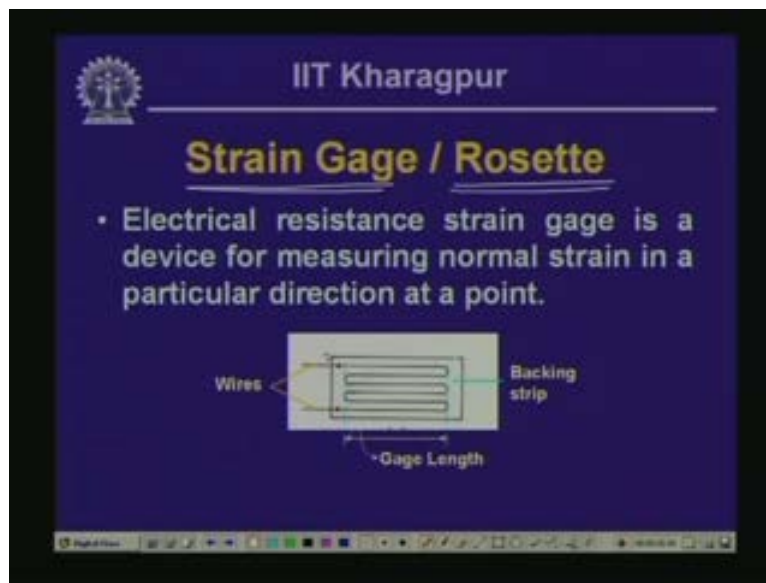

(Refer Slide Time: 9:06)

Having looked into these questions now let us look into the aspects which we are going to discuss today: the concept of the strain gage and consequently the term which is called as Strain Rosette. Many a times what we need to do is that experimentally we need to measure the strain at a point in a stressed body and that can be done using a device which we call as Strain Gage.

Electrical resistance strain gage is one such device using which we can evaluate strain at a point in a stressed body. The mechanism of this particular strain gage works with a wire which is pasted on a paper base and this can be fixed onto the stressed body as the body undergoes strain or deformation the gage also along with the body undergoes deformation and thereby there is a change in the resistance of that particular wire which is evaluated in terms of the strain and that is the basic principal. The strain gages can be used for measuring strain at a point or specifically the normal strain at a point in a particular direction.

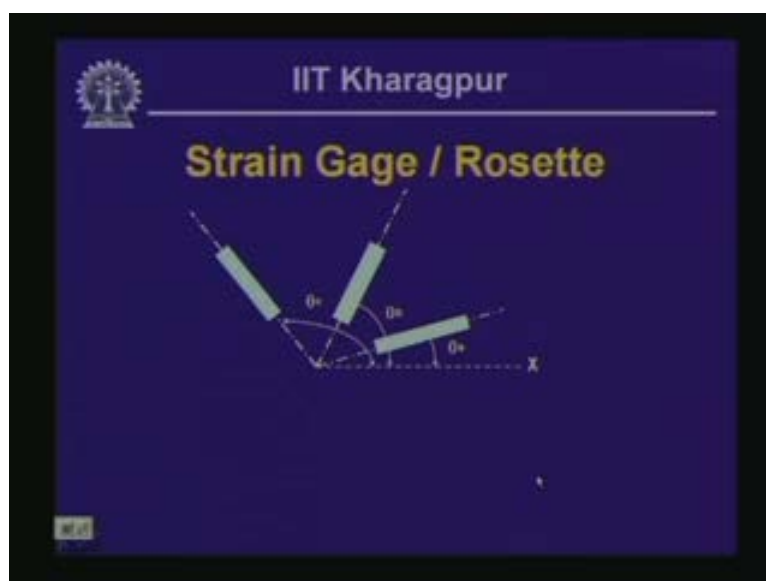

(Refer Slide Time: 10:21)

This is the configuration of the strain gage as shown here where this particular area is the backing strip over which the wire is placed and this is the gage length of the strain gage. Various sizes of the strain gages are available, they range between 2 mm to even 40 mm to 50 mm size.

Depending on the usage depending on the type of strain we are looking for or the accuracy in the strain we are looking for we use such gages to measure the strain at a particular point. From this particular strain values we need the normal strain  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  and if we have those information then we can compute the value of principal strains  $\epsilon_1$ ,  $\epsilon_2$ ; we can evaluate the stresses from those strains. So if measurement of strain at a point using such strain gages is a useful aspect in Strength of Materials.

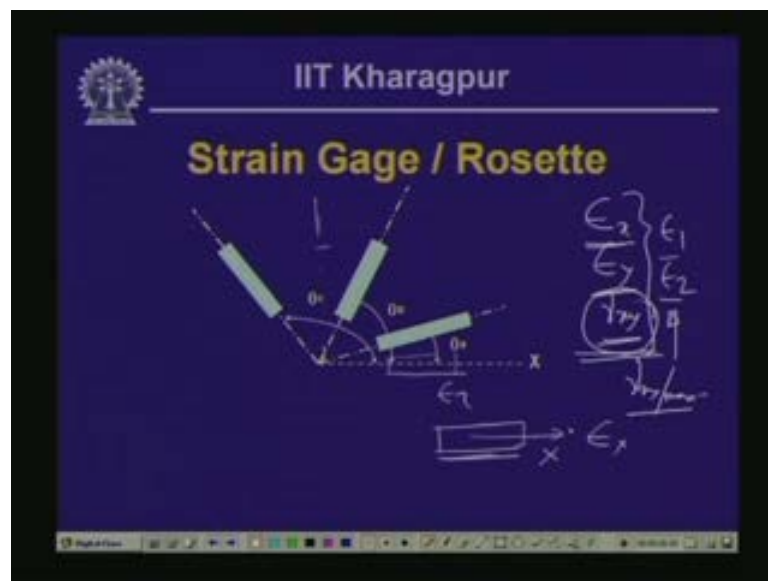

(Refer Slide Time: 11:32)

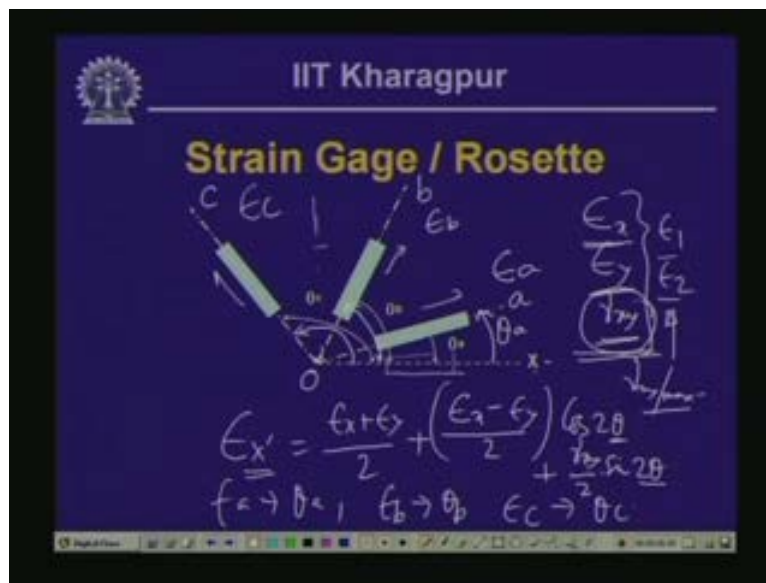

In a plane strain we need to have three quantities. They are:  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$ . And if we can have these quantities then we can compute the strain values which are  $\epsilon_1$ ,  $\epsilon_2$ , the principal strains, they are directions, the maximum shearing strain which is  $\gamma_{xy\max}$ , and once we have the values of the principal strains we can compute the values of principal stresses as well which are related between the strains and the stress. Therefore we can evaluate the stress at that particular point. But the point is the strain gage which we use can be used for measuring the normal strain. If we place the strain gage along the x-direction we can get the value of  $\epsilon_x$  and if we place them in the y-direction we can get the value of  $\epsilon_y$  but the problem is with the  $\gamma_{xy}$ .

(Refer Slide Time: 12:47)

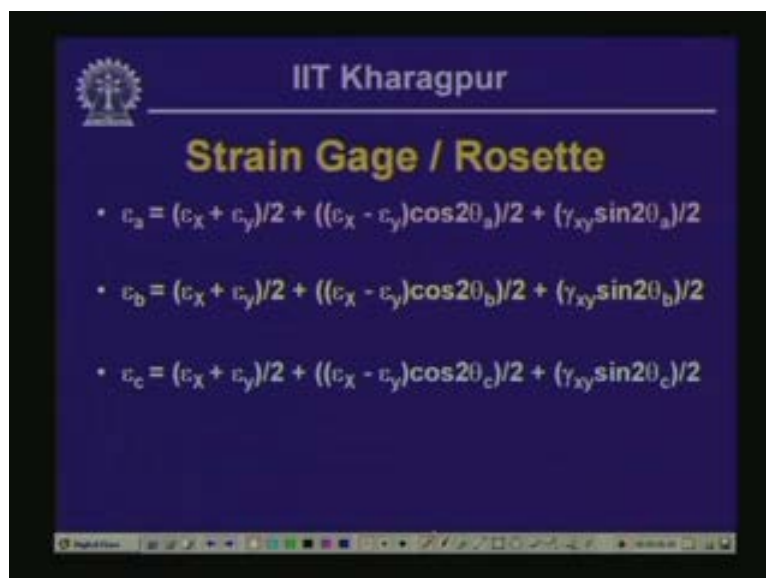

We cannot measure the shearing strain  $\gamma_{xy}$  directly as we can measure the normal strain  $\epsilon_x$  and  $\epsilon_y$  using the strain gages oriented in that particular direction because strain gage gives us the normal strain at that particular point so we can evaluate  $\epsilon_x$  and  $\epsilon_y$  but measurement of  $\gamma_{xy}$  is difficult. Therefore we take an indirect path to evaluate  $\gamma_{xy}$  so that we can utilize this information for evaluating principal strains and thereby the stresses. The indirect path is like this, what we do is that if we install strain gages along three directions, let us call this is direction a, this is direction b, and this is direction c.

(Refer Slide Time: 15:12)

Now if we place strain gage along Oa, Ob, and Oc then we can get the normal strains  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  in three directions. Let us assume that the direction Oa is oriented at an angle of  $\theta_a$  with reference x-axis and likewise Ob is oriented at an angle of  $\theta_b$  with reference x-axis, and Oc is oriented at an angle of  $\theta_c$  with reference x-axis. If we have these information, if you remember, we calculated the transformation equations as  $\epsilon_{x'}$  is equal to  $(\epsilon_x + \epsilon_y) / 2 + (\epsilon_x - \epsilon_y) / 2 \cos 2\theta + \gamma_{xy} / 2 \sin 2\theta$ . In this particular case x prime direction with theta the  $\epsilon_a$  is corresponding to  $\theta_a$ ,  $\epsilon_b$  is corresponding to  $\theta_b$  and  $\epsilon_c$  is corresponding to  $\theta_c$ . If we substitute for  $\theta_a$ ,  $\theta_b$ ,  $\theta_c$  correspondingly we can get the values of  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  and this is what is done over here.

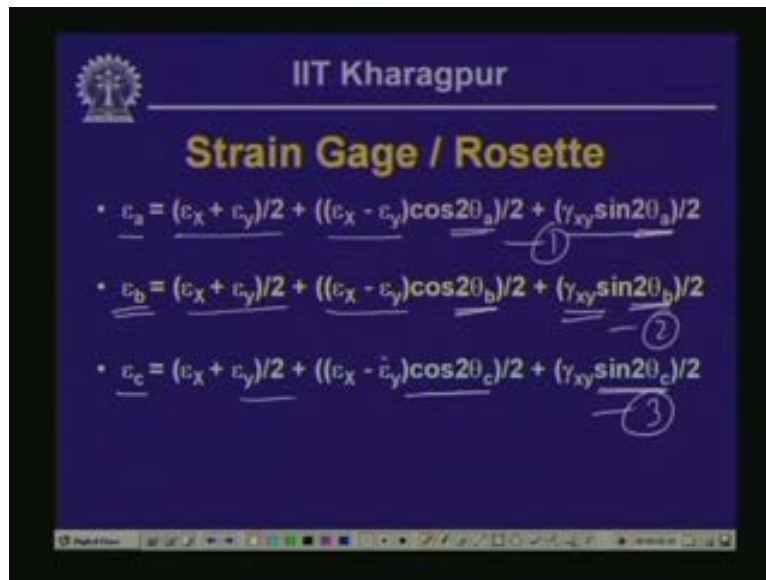

(Refer Slide Time 15:19)

The  $\epsilon_a$  is equal to  $(\epsilon_x + \epsilon_y) / 2 + (\epsilon_x - \epsilon_y) \cos 2\theta_a / 2 + \gamma_{xy} \sin 2\theta_a / 2$  likewise  $\epsilon_b$  is equal to  $(\epsilon_x + \epsilon_y) / 2 + (\epsilon_x - \epsilon_y) \cos 2\theta_b / 2 + \gamma_{xy} \sin 2\theta_b / 2$  and  $\epsilon_c$  is equal to  $(\epsilon_x + \epsilon_y) / 2 + (\epsilon_x - \epsilon_y) \cos 2\theta_c / 2 + \gamma_{xy} \sin 2\theta_c / 2$ .

$2\epsilon_x - \epsilon_y) \cos 2\theta_a$  by 2 plus  $(\gamma_{xy} \sin 2\theta_a)$  by 2 and  $\epsilon_c$  is equal to  $(\epsilon_x + \epsilon_y)$  by 2 plus  $(\epsilon_x - \epsilon_y) \cos 2\theta_c$  by 2 plus  $(\gamma_{xy} \sin 2\theta_c)$  by 2. We have three equations: equation 1, equation 2, and equation 3 and out of these three equations we know the value of  $\epsilon_a$ , we know the value of  $\epsilon_b$ , and we know the value of  $\epsilon_c$ .

(Refer Slide Time: 15:59)

Also, we know the orientation angles  $\theta_a$ ,  $\theta_b$  and  $\theta_c$ . Since these three parameters or six parameters are known  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  are known; consequently  $\theta_a$ ,  $\theta_b$ ,  $\theta_c$  are known. The unknown parameters  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$  can be evaluated from these three equations. Therefore we can compute  $\epsilon_x$  we can compute  $\epsilon_y$ , and we can compute  $\gamma_{xy}$  from these equations. Once we know  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$  then using these three quantities we can evaluate strain at any orientation as we desire as we have seen either using transformation equations or using Mohr circle or we can evaluate even the principal strains and consequently evaluate principal stresses from the material properties.

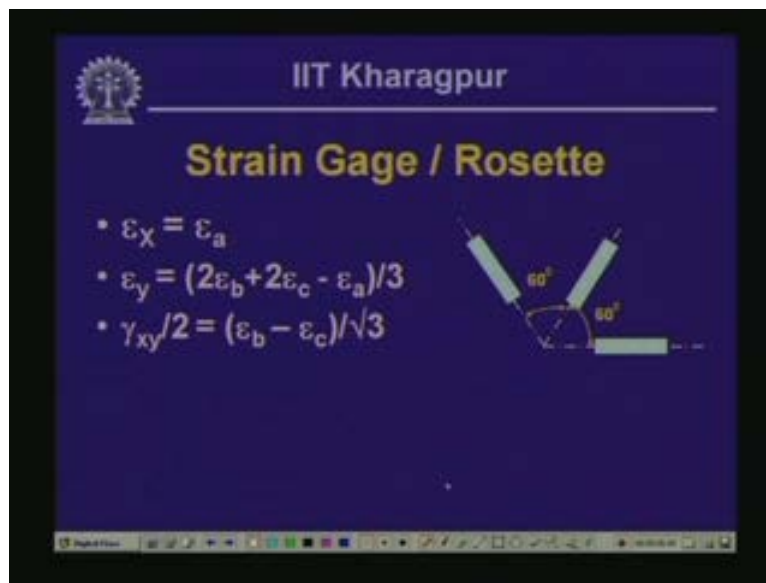

(Refer Slide Time: 19:55)

When we use the strain gages together to measure the strain at a particular point we call that assembly as the strain rosette; the formation of three gages together is termed as strain rosette. These angles shown as  $\theta_a$ ,  $\theta_b$  and  $\theta_c$  can be chosen according to our own convenience and normally the angles used are the 45 degrees or 60 degrees and now this is called as a 45 degrees strain rosette. Here two angles used are;  $\theta_a$  is 45 degrees and  $\theta_b$  is 45 degrees. Now along the x-direction we have oriented a, along 45 degrees we have b, along 90 degrees we have c.

Since  $\epsilon_a$  are the strain along a is coinciding with the x axis so  $\epsilon_x$  is  $\epsilon_a$  directly. Likewise since this particular gage c is oriented in the direction of y the  $\epsilon_y$  is equal to  $\epsilon_c$ ; so directly we can get the values of  $\epsilon_x$  and  $\epsilon_y$  from the measured strain value of  $\epsilon_a$  and  $\epsilon_b$ . What we need to do is evaluation of  $\gamma_{xy}$ . Again if we go back to the transformation equation which is  $\epsilon_{x'}$  is equal to  $(\epsilon_x + \epsilon_y) \cos^2\theta + (\epsilon_x - \epsilon_y) \sin^2\theta + \gamma_{xy} \sin 2\theta$ . Now  $\theta$  here is 45 degrees so  $\sin 90$  is 1,  $\cos^2 45$  is equal to 0.5, so this term goes off and this is  $\gamma_{xy} \sin 90$  by 2 and this is in direction of 45 degrees which is  $\epsilon_b$  so  $\epsilon_b$  is equal to  $\epsilon_x + \epsilon_y$  plus  $\gamma_{xy}$  by 2. From this it gives  $\gamma_{xy}$  by 2 is equal to  $\epsilon_b - \epsilon_x - \epsilon_y$  so we get the value of  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$  from the measurement of this particular type of strain rosette which can be utilized for evaluating the strain or the principal strain at that particular point and those principal strains can be utilized for evaluating stresses at that particular point.

(Refer Slide Time: 22:57)

The slide features the IIT Kharagpur logo and title at the top. Below the title, three equations are listed on the left, and a diagram of a 60-degree strain rosette is on the right. The diagram shows three strain gages: one horizontal (labeled 'a'), and two others at 60-degree angles from the horizontal (labeled 'b' and 'c').

IIT Kharagpur

### Strain Gage / Rosette

- $\epsilon_x = \epsilon_a$
- $\epsilon_y = (2\epsilon_b + 2\epsilon_c - \epsilon_a)/3$
- $\gamma_{xy}/2 = (\epsilon_b - \epsilon_c)/\sqrt{3}$

Another kind of strain rosette is oriented at an angle of 60 degrees, again the whole assembly the three strain gages fixed in this particular form can be fixed on the surface where we like to measure the strain, and at that particular point we are measuring strains in three different directions which are oriented at an angle of 60 degrees with reference to the different x axis.

This is reference x-axis and now the y-axis here is in this direction; so let us call this as direction a, this as b, and this as c. So as usual since the strain in the gage a is in the x-direction, so  $\epsilon_x$  will directly give us  $\epsilon_a$ . Now here neither the gage is oriented in the direction y so  $\epsilon_y$  we cannot get directly and we cannot evaluate the value of  $\gamma_{xy}$  directly as we have seen earlier so we have to find the values of  $\epsilon_y$  and  $\gamma_{xy}$  from the measure strain in the direction of b and c.

To evaluate the strain value at  $\epsilon_y$  and  $\gamma_{xy}$  we make use of the transformation equation which is again  $\epsilon_{x'}$  is equal to  $\epsilon_x \cos^2 \theta + \epsilon_y \sin^2 \theta + \gamma_{xy} \sin 2\theta$ . When we substitute for b that is  $\epsilon_b$  is equal to  $\epsilon_x \cos^2 60^\circ + \epsilon_y \sin^2 60^\circ + \gamma_{xy} \sin 120^\circ$ , now  $\epsilon_x$  is already  $\epsilon_a$  by  $2\epsilon_a \cos^2 60^\circ + \epsilon_y \sin^2 60^\circ + \gamma_{xy} \sin 120^\circ$  where theta being 60 degrees this is  $\epsilon_a \cos^2 120^\circ + \epsilon_y \sin^2 120^\circ + \gamma_{xy} \sin 240^\circ$ .

Likewise we evaluate the strain in the c direction  $\epsilon_c$  is equal to  $\epsilon_x \cos^2 120^\circ + \epsilon_y \sin^2 120^\circ + \gamma_{xy} \sin 240^\circ$  and once we substitute the values of that then we get two equations in  $\epsilon_b$  and  $\epsilon_c$  and we have two unknown parameters  $\epsilon_y$  and  $\gamma_{xy}$  and these two can be solved and if we solve that we will get the values of  $\epsilon_y$  and  $\gamma_{xy}$  in terms of  $\epsilon_b$  and  $\epsilon_c$ .

We have again three quantities  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$  in terms of  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  and that was our objective as to find the values of  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$  in terms of  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  and that was what our objective: to find out the values of  $\epsilon_x$ ,  $\epsilon_y$  and  $\tau_{xy}$  in terms of  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  and these are the three normal strains which we have measured at a point based on which we can compute other quantities as we desire.

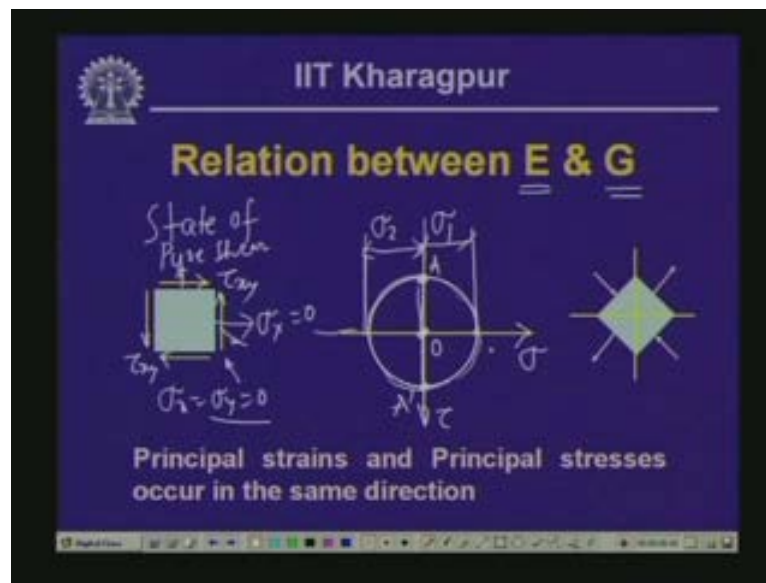

(Refer Slide Time: 26:25)

This is another important aspect wherein we need to relate the quantity which is  $E$  which we call as modulus of elasticity to the quantity  $G$  which we call as the modulus of the rigidity. We have already seen the definition of  $E$  and  $G$  earlier and now we like to relate these two quantities  $E$  and  $G$ . Let us look into state of stress at a point where the stresses are all shearing, stresses acting at that particular point in this element. Here the normal stresses  $\sigma_x$  and  $\sigma_y$  is equal to 0 and the shearing stresses are  $\tau_{xy}$ . If you remember, this kind of stress distribution is called as the state of pure shear. This is a state of pure shear.

Now if we try to plot this stress in the Mohr circle, and as we have seen, this is our  $\sigma$ -axis and this is our  $\tau$ -axis and now on this particular plane  $\sigma$  the normal stress is equal to 0 when we have only positive  $\tau_{xy}$  which is causing anticlockwise moment and correspondingly if you place  $\sigma$  this is  $\sigma$  axis,  $\sigma_x$  is 0 and we have positive  $\tau$  so this is a point which can be represented by this particular stress value and in the perpendicular direction again  $\sigma_y$  is 0 so we have normal stress 0 and negative of  $\tau$  which is this particular point. So, considering this as the center let us call this  $o$  as center and  $oA$  or  $oA'$  as the radius and now if we draw the circle this gives us the Mohr circular stress corresponding to the pure state of shear at a particular point.

(Refer slide time: 25:47)

In this diagram this is the maximum normal stress which we call as  $\sigma_1$  and this is the minimum normal stress which we call as  $\sigma_2$ . Please observe that the maximum stress point  $oo$  prime or the minimum stress point  $oo$  double prime are of the same magnitude which is equal to the radius of the circle. The radius of the circle is  $\tau_{xy}$  so  $\sigma_1$  is equal to  $\tau_{xy}$  and  $\sigma_2$  is equal to minus  $\tau_{xy}$  and this is the element where the principal stresses  $\sigma_1$  and  $\sigma_2$  are acting. Now this aspect must be noted, we have seen consequently when we were evaluating the direction for the principal strain. We have seen that the direction of the principal stress at a point and direction of the principal strain match. In fact they are oriented at an angle of 45 degrees with reference to the reference x-axis.

Hence the principal strains and principal stresses occur in the same direction. This is quite important. We know that in this particular point if we would like to find out the strain  $\epsilon_1$  we can compute that  $\epsilon_1$  is equal to  $\sigma_1$  by  $(E)$  minus  $\mu$  [ $\sigma_2$  by  $E$ ]. This is the plane state of stress that is acting in this  $\sigma_1$  and  $\sigma_2$ . And if we like to evaluate the strain  $\sigma_1$  by  $E$  is the direct because of the Poisson effect so  $\epsilon_1$  is equal to  $\sigma_1$  by  $(E)$  minus  $\mu$   $\sigma_2$  by  $(E)$ . Now if we substitute for the value of  $\sigma_1$  and  $\sigma_2$ , we have  $\epsilon_1$  is equal to  $\sigma_1$  by  $E$  minus  $\mu$   $\sigma_2$  by  $E$  and as we have seen that  $\sigma_1$  is equal to  $\tau_{xy}$  and  $\sigma_2$  is equal to minus  $\tau_{xy}$  hence  $\epsilon_1$  is equal to  $\tau_{xy}$  by  $E$  minus  $\mu$  (minus  $\tau_{xy}$ ) by  $E$  is equal to  $1$  plus  $\mu$   $\tau_{xy}$  by  $E$ . Let us call this as equation 1.

(Refer Slide Time: 29:27)

The image shows a whiteboard with handwritten mathematical derivations. The equations are as follows:

$$\epsilon_1 = \frac{\sigma_1}{E} - \frac{\nu\sigma_2}{E} \quad \begin{matrix} \sigma_x = \sigma_y = 0 \\ \epsilon_x = 0 \\ \sigma_1 = \tau_{xy}, \sigma_2 = -\tau_{xy} \\ \epsilon_y = 0 \end{matrix}$$

$$\epsilon_1 = \frac{\tau_{xy}}{E} - \frac{\nu(-\tau_{xy})}{E}$$

$$= (1 + \nu) \frac{\tau_{xy}}{E} \quad \text{--- (1)}$$

$$\epsilon_{x'} = \frac{\epsilon_x + \epsilon_y}{2} + \left( \frac{\epsilon_x - \epsilon_y}{2} \right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$$

$\theta = 45^\circ$

$$\epsilon_1 = \frac{\gamma_{xy}}{2}$$

We have seen that the strain at any direction  $\epsilon_{x'}$  is equal to  $\epsilon_x$  plus  $\epsilon_y$  by 2 plus  $(\epsilon_x$  minus  $\epsilon_y$  by 2)  $\cos 2\theta$  plus  $\gamma_{xy}$  by 2  $\sin 2\theta$ . Since the direction of principal stress coincides with the direction of the principal strain then also that we have noted that  $\sigma_x$  is equal to  $\sigma_y$  is equal to 0 so since normal stresses are 0 and the corresponding normal strains are also 0;  $\epsilon_x$  is equal to 0 and  $\epsilon_y$  is equal to 0 hence the first term is 0.

Now since the direction of the principal strain is also  $\theta$  is equal to 45 degrees then  $\cos 90$  is 0 and thereby  $\sin 90$  is 1 so  $\epsilon_1$  the strain in the principal direction is equal to  $\gamma_{xy}$  by 2. Now the relation between the shearing stress and the shearing strain can be related through the shear modulus using the Hooke's law. So  $\tau_{xy}$  is equal to  $G(\gamma_{xy})$  where  $\tau_{xy}$  is the shearing stress and  $G$  is the shear modulus. Now  $\gamma_{xy}$  you can substitute in terms of  $\tau_{xy}$  is equal to  $\tau_{xy}$  by  $2G$  so this is the second equation.

(Refer Slide Time: 29:58)

$$\epsilon_1 = \frac{\sigma_1}{E} - \frac{\mu\sigma_2}{E} \quad \begin{matrix} \sigma_x = \sigma_y = 0 \\ \epsilon_x = 0 \\ \sigma_1 = \tau_{xy}, \sigma_2 = -\tau_{xy} \\ \epsilon_y = 0 \end{matrix}$$

$$\epsilon_1 = \frac{\tau_{xy}}{E} - \frac{\mu(-\tau_{xy})}{E}$$

$$= \frac{(1+\mu)\tau_{xy}}{E} \quad \text{--- (1)}$$

$$\epsilon_x = \frac{\epsilon_x + \epsilon_y}{2} + \left(\frac{\epsilon_x - \epsilon_y}{2}\right) \cos 2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$$

$$\theta = 45^\circ \quad \tau_{xy} = G \cdot \gamma_{xy}$$

$$\epsilon_1 = \frac{\gamma_{xy}}{2} = \frac{\tau_{xy}}{2G} \quad \text{--- (2)}$$

So, in the first equation we have  $\epsilon_1$  is equal to  $(1 + \mu)\tau_{xy}$  by  $E$  and the second equation which we have is  $\epsilon_1$  is equal to  $\tau_{xy}$  by  $2G$ . If we equate these two, in the first place we have  $(1 + \mu)\tau_{xy}$  by  $E$  is equal to  $\tau_{xy}$  by  $2G$ . Hence the  $\tau_{xy}$  and  $\tau_{xy}$  gets cancelled so  $G$  is equal to  $E$  by  $2$  into  $1 + \mu$ .

(Refer Slide Time: 31:00)

$$(1+\mu) \frac{\tau_{xy}}{E} = \frac{\tau_{xy}}{2G}$$

$$\boxed{G = \frac{E}{2(1+\mu)}}$$

This is the relationship between the shear modulus  $G$  and the elastic modulus  $E$  through the term Poisson's ratio. This is the relationship between  $E$ ,  $G$ , and  $\mu$ . Now please note that these are the three quantities  $E$ ,  $G$ , and  $\mu$  these three elastic constants are necessary for evaluating deformation at a particular point but out of these three quantities two are independent and one can be evaluated in terms of the other two.

(Refer Slide Time: 31:23)

IIT Kharagpur

## Relation between E & G

- $\epsilon_1 = (\sigma_1 - \mu \cdot \sigma_2)/E = (\tau_{xy} - \mu (-\tau_{xy}))/E$
- $\epsilon_1 = (1 + \mu) \cdot \tau_{xy} / E$
- $\epsilon_x = (\epsilon_x + \epsilon_y)/2 + ((\epsilon_x - \epsilon_y)\cos 2\theta)/2 + (\gamma_{xy}\sin 2\theta)/2$
- For  $\epsilon_x = \epsilon_y = 0$  &  $2\theta = 90^\circ$
- $\epsilon_1 = \gamma_{xy} / 2 = \tau_{xy} / 2G$

$$G = E / (2(1+\mu))$$

These are the expressions which we have just derived. It is written over here epsilon<sub>1</sub> is equal to 1 plus mu tau<sub>xy</sub> by E and then epsilon<sub>xprime</sub> is equal to epsilon<sub>x</sub> plus epsilon<sub>y</sub> by 2 plus epsilon<sub>x</sub> minus epsilon<sub>y</sub> cos 2theta by 2 and for epsilon<sub>xprime</sub> epsilon<sub>y</sub> is equal to 0 and 2theta is equal to 90 degrees if we relate these two we have G is equal to E by (2(1 plus mu)). This is the relationship between E and G through the term Poisson's ratio mu is the Poisson's ratio. Let us look into another quantity which we define as bulk modulus.

IIT Kharagpur

## Bulk Modulus

- Dilatation, change in volume per unit volume for infinitesimal strain is given as:
- $e = \epsilon_x + \epsilon_y + \epsilon_z$
- $e = (1 - 2\mu)(\sigma_x + \sigma_y + \sigma_z)/E$
- $e = -3(1 - 2\mu)p/E$

$$-p/e = K = E / (3(1 - 2\mu))$$

Many a times we need to know the volume change at a particular stressed body and if we try to find out we generally come up with another constant k which we call as bulk modulus which is related to the change in the volume in a stressed body. Now let us look at a point where a small body which is having a dimension dx, dy, and dz.

(Refer Slide Time: 36:13)

$$\begin{aligned}
 & \text{dx} \quad \text{dy} \quad \text{dz} \\
 & V_0 = dx \cdot dy \cdot dz \\
 & V' = (dx + \epsilon_x dx)(dy + \epsilon_y dy)(dz + \epsilon_z dz) \\
 & = \frac{dx \cdot dy \cdot dz (1 + \epsilon_x)(1 + \epsilon_y)(1 + \epsilon_z)}{(1 + \epsilon_x)(1 + \epsilon_y)(1 + \epsilon_z)} \\
 & = V_0 (1 + \epsilon_x + \epsilon_y + \epsilon_z + \epsilon_x \epsilon_y + \epsilon_y \epsilon_z + \epsilon_x \epsilon_z + \epsilon_x \epsilon_y \epsilon_z) \\
 & \approx V_0 (1 + \epsilon_x + \epsilon_y + \epsilon_z) \\
 & \frac{\Delta V}{V_0} = \frac{V' - V_0}{V_0} = \epsilon_x + \epsilon_y + \epsilon_z = e
 \end{aligned}$$

This is dx, dy, and dz the elemental length so the  $V_0$  is equal to  $dx(dy(dz))$ . Now after this particular element has undergone strain there will be extension in all three directions and thereby there will be change in the volume. Let us say that the strains in the x, y, and z directions are  $\epsilon_x$ ,  $\epsilon_y$  and  $\epsilon_z$  and thereby the extensions in the x direction will be  $\epsilon_x(dx)$ ; and the extension in the y direction will be  $\epsilon_y(dy)$ ; and the extension in the z direction will be  $\epsilon_z(dz)$ .

The changed volume accordingly will be equal to let us call this V prime as dx plus  $\epsilon_x dx$  is the changed length in the x direction; dy plus  $\epsilon_y dy$  is the changed length in the y direction ( $dz$  plus  $\epsilon_z dz$ ). Or this we can write as dx dy dz, if we take out dx, dy, dz, we have  $1 + \epsilon_x(1 + \epsilon_y)(1 + \epsilon_z)$ . If we expand this, now dx dy dz as we have seen is the initial volume which is  $V_0$  times if we expand this then it is  $1 + \epsilon_x + \epsilon_y + \epsilon_z + \epsilon_x \epsilon_y + \epsilon_y \epsilon_z + \epsilon_x \epsilon_z + \epsilon_x \epsilon_y \epsilon_z$ . This is the expression which we are going to get if we multiply these three quantities.

Since the strain is small  $\epsilon_x$ ,  $\epsilon_y$ ,  $\epsilon_z$  they are small quantities so the product of these quantities  $\epsilon_x \epsilon_y$  and  $\epsilon_x \epsilon_z$  and  $\epsilon_y \epsilon_z$  and  $\epsilon_x \epsilon_y \epsilon_z$  we consider them as 0 or insignificant. Hence this is equal to  $V_0 (1 + \epsilon_x + \epsilon_y + \epsilon_z)$  and this V prime minus  $V_0$  by  $V_0$  is equal to  $\epsilon_x + \epsilon_y + \epsilon_z$ .

Now V prime minus  $V_0$  is the change in the volume  $\Delta V$ . Now  $\Delta V$  by  $V_0$  is equal to  $\epsilon_x + \epsilon_y + \epsilon_z$  and this we denote by quantity e. And in fact this is known as dilatation that the change in volume per unit  $V_0$  is unit then change in volume  $\Delta V$  gives e. So, dilatation is the quantity which is called as the change in volume per unit volume represented in terms of strain as  $\epsilon_x + \epsilon_y + \epsilon_z$ . Now we know the relationship between the strain and stress which is  $\epsilon_x$  is equal to  $\sigma_x$  by E minus  $\mu(\sigma_y + \sigma_z)$  by E.

(Refer Slide Time: 39:44)

$$\epsilon_x = \frac{\sigma_x}{E} - \frac{\mu(\sigma_y + \sigma_z)}{E}$$

$$\epsilon_y = \frac{\sigma_y}{E} - \frac{\mu(\sigma_x + \sigma_z)}{E}$$

$$\epsilon_z = \frac{\sigma_z}{E} - \frac{\mu(\sigma_x + \sigma_y)}{E}$$

$$e = \epsilon_x + \epsilon_y + \epsilon_z = \frac{\sigma_x + \sigma_y + \sigma_z}{E} - \frac{2\mu(\sigma_x + \sigma_y + \sigma_z)}{E}$$

$$e = \frac{(1-2\mu)}{E} (\sigma_x + \sigma_y + \sigma_z)$$

$$e = \frac{3p}{E(1-2\mu)}$$

Likewise  $\epsilon_y$  is equal to  $\frac{\sigma_y}{E} - \mu(\frac{\sigma_x + \sigma_z}{E})$  by E. This we have seen while discussing the generalized Hooke's law and  $\epsilon_z$  is equal to  $\frac{\sigma_z}{E} - \mu(\frac{\sigma_x + \sigma_y}{E})$  by E. Now if we add together  $e$  is equal to  $\epsilon_x + \epsilon_y + \epsilon_z$  as we have seen and this equal to in terms of stresses as  $\frac{\sigma_x + \sigma_y + \sigma_z}{E} - 2\mu(\frac{\sigma_x + \sigma_y + \sigma_z}{E})$  by E is equal to  $(1 - 2\mu) \frac{\sigma_x + \sigma_y + \sigma_z}{E}$ . So  $e$  is related to the stress as  $(1 - 2\mu) \frac{\sigma_x + \sigma_y + \sigma_z}{E}$ .

Now, if we take that small body from which we evaluated this quantity, and if we say that the stresses acting on this particular body  $\sigma_x$ ,  $\sigma_y$  and  $\sigma_z$  are all of magnitude  $p$  acting in the compressive direction on all sides then it is called as the state of hydrostatic pressure. That means a body is subjected to pressure from all directions. Thereby the  $\sigma_x$ ,  $\sigma_y$  and  $\sigma_z$  are of equal value and they are of magnitude  $p$  and this particular state of stress in a body we call as state of hydrostatic pressure.

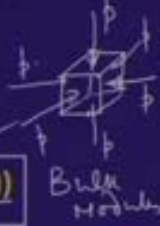

If we replace the value of  $\sigma_x$ ,  $\sigma_y$  and  $\sigma_z$  in terms of  $p$  then since it is acting in the compressive direction they are minus so  $\sigma_x$  is equal to minus  $p$ ;  $\sigma_y$  is equal to minus  $p$  and  $\sigma_z$  is equal to minus  $p$  and minus  $e$  is equal to minus  $\frac{3p}{E(1-2\mu)}$  and this is the quantity minus  $p$  by  $e$  is equal to  $\frac{E}{3(1-2\mu)}$  and this particular quantity minus  $p$  by  $e$  is normally designated as the bulk modulus  $k$ . So  $k$  is related to this elastic modulus  $E$  and Poisson's ratio  $\mu$  as  $k$  is equal to  $\frac{E}{3(1-2\mu)}$  and this is what has been discussed here.

IIT Kharagpur

## Bulk Modulus

- Dilatation, change in volume per unit volume for infinitesimal strain is given as:
- $e = \epsilon_x + \epsilon_y + \epsilon_z$
- $e = \frac{(1 - 2\mu)(\sigma_x + \sigma_y + \sigma_z)}{E}$
- $e = -\frac{3(1 - 2\mu)p}{E}$
- $\boxed{-p/e = K = E / (3(1 - 2\mu))}$  Bulk Modulus

These are the expressions as we have derived right now that epsilon is equal to epsilon<sub>x</sub> plus epsilon<sub>y</sub> plus epsilon<sub>z</sub> and e is equal to 1 - 2 mu (sigma<sub>x</sub> plus sigma<sub>y</sub> plus sigma<sub>z</sub> by E and e is equal to minus 3(1 minus 2mu) p by E when the element is subjected to the state of hydrostatic pressure that in all directions it is subjected to p and because of this the state of stress sigma<sub>x</sub> plus sigma<sub>y</sub> plus sigma<sub>z</sub> is minus 3p this gives us the expression e equal to this and thereby the quantity minus p by e we call as the bulk modulus and bulk modulus value is equal to E by 3(1 minus 2mu). This term is defined as dilatation which is the change in volume per unit volume for a small infinitesimal strain which is given by this expression e.

IIT Kharagpur

## Example Problem - 1

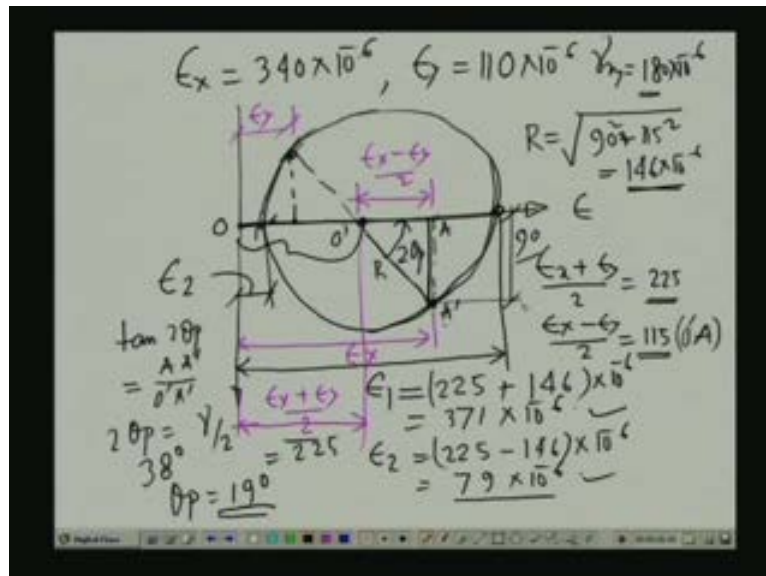

- The state of plane strain at a point in a body is given by  $\epsilon_x = 340 \times 10^{-6}$ ;  $\epsilon_y = 110 \times 10^{-6}$  and  $\gamma_{xy} = 180 \times 10^{-6}$ . Determine the strain components if the axes are oriented at an angle of  $30^\circ$  with reference axes in anticlockwise direction. Determine the Principal strains. Use Mohr's circle. Also, compute Principal strain direction and maximum shear strain.

Example problem:

After looking into the aspects of strains as discussed through transformation equations, through Mohr circle, and also we have seen usage of strain gages and the strain rosettes from

which we can find out the values of normal strains in different directions which can be utilized for the evaluation of the principal strain at a particular point from which we can compute the values of principal stresses. Last time I solved one example using the Mohr circle of strain. Now the values of  $\epsilon_x$  is given as this,  $\epsilon_y$  as this and  $\gamma_{xy}$  as this. What you need to do is to compute the values of the principal strains and their directions and also the maximum shearing strain based on these data using Mohr circle of strain and we will have to find out the strains at a direction which is oriented at 30 degrees in an anticlockwise direction with reference to the x-axis.

(Refer Slide Time: 48:36)

Plotting the Mohr circle:

Now given values are  $\epsilon_x$  is equal to 340 into 10 to the power minus 6,  $\epsilon_y$  is equal to 110 into 10 to the power minus 6 and  $\gamma_{xy}$  is equal to 180 into 10 to the power minus 6. If we plot this in the Mohr circle this is the gamma by 2 direction and this is epsilon direction. Here we have  $\epsilon_x$  is equal to 340 and gamma by 2 is equal to 90 so this is the point which we choose here; we have another point  $\epsilon_y$  which is 110 and gamma by 2 is minus 90 so we place the point here and as per the norm of the Mohr circle we join these two points and thereby this gives us the center of the Mohr circle. And if we plot the circle considering this as center and this as radius we get the circle. This particular point gives us the point of maximum normal strain which we define as  $\epsilon_1$  and this is the minimum normal strain which we define as  $\epsilon_2$ .

In this figure this is  $\epsilon_x$  and  $\epsilon_y$  hence this is  $\epsilon_x$  minus  $\epsilon_y$  by 2 and thereby this distance is  $\epsilon_x$  plus  $\epsilon_y$  by 2. The values of this if we calculate  $\epsilon_x$  plus  $\epsilon_y$  by 2 is equal to 340 plus 110 is equal to 450 hence 225 into 10 to the power minus 6 then  $\epsilon_x$  minus  $\epsilon_y$  by 2 is equal to 230 by 2 is equal to 115. Now the normal strain  $\epsilon_1$  will be the distance from o to o prime plus the radius. The radius can be computed from this triangular configuration where let us call this as a and this as A prime now AA prime is equal to tau by 2 is equal to 90(10 to the power minus 6) and this distance is  $\epsilon_x$  minus  $\epsilon_y$  by 2 is equal to 115 so the radius R is equal to square root of 90(10 to the power 6) square plus 115 square and this gives us a value of 146(10 to the power 6). Now this quantity is with 10 to the power minus 6 which I am keeping silent here, so R is

equal to  $146(10 \text{ to the power minus } 6)$ . So the value of maximum normal strain  $\epsilon_1$  is equal to  $oo \text{ prime plus } o \text{ prime plus } R$  and  $oo \text{ prime}$  is equal to  $\epsilon_x \text{ plus } \epsilon_y \text{ by } 2$  which is equal to 225. So 225 plus 146, this gives us the value of the normal strain maximum which is 371;  $371(10 \text{ to the power minus } 6)$  is the maximum normal strain.

The minimum normal strain  $\epsilon_2$  is equal to this particular distance again is the distance from  $o$  to  $o \text{ prime}$  minus the radius so  $oo \text{ prime}$  is again 225 minus radius is 146 ( $10 \text{ to the power minus } 6$ ) this gives us the value of 79 ( $10 \text{ to the power minus } 6$ ). So these are the values of the maximum normal and the minimum normal, the principal strains. We need to know the orientation of the principal strains and this is the reference  $x$  axis where the normal

$\epsilon_x$  and  $\frac{\gamma_{xy}}{2}$  two positive occurs now from here. If you rotate by angle  $2\theta_p$ , this gives

us the position of the maximum normal strain and from this particular triangle  $o \text{ prime AA prime}$  we can get  $\tan 2\theta_p$   $\tan 2\theta_p$  is equal to  $AA \text{ by } o \text{ prime A prime}$  and that gives us the value of which is  $AA \text{ prime}$  is 90 and  $o \text{ prime A}$  is equal to 115. So  $19 \text{ by } 115 \tan \text{ inverse}$  gives us the value of 38;  $2\theta_p$  is equal to 38 degrees and thereby  $\theta_p$  is equal to 19 degrees. So this is the orientation along which the maximum principal strain occurs. Now what we need to do is to evaluate the strains at a direction which is oriented at an angle of 30 degrees with reference to the reference  $x$ -axis. So if it is oriented at an angle of 30 degrees in the Mohr's plane, it is twice the  $\theta$  so it is 60 degrees.

Now with reference to the positive  $\epsilon_x$  and  $\frac{\gamma_{xy}}{2}$  if we orient by 60 degrees so this is the

60 degrees point and if we join the line from center to this we get this particular point which is the direction where we need the strain and this will give us the value of this is the normal strain, and this is the value of the shearing strain  $\gamma_{x \text{ prime } y \text{ prime}}$  by 2. Now this particular angle is 38 degrees and this total angle is 60 degrees; so 60 minus 38 this is if we call this as  $\alpha$  is equal to 22 degrees. Now if we can compute the value of  $a$ , and this distance  $b$ , then

we can find out the normal stress which is  $oo \text{ prime plus } b$  and shearing strain is  $\frac{\gamma_{xy}}{2}$ ;  $x \text{ prime}$

$y \text{ prime}$  by 2 is equal to  $a$  or which is minus  $a$  that is negative in the Mohr's plane. So if we compute those two values now this is the radius  $R \cos \alpha$  will give us this particular distance and our  $\sin \alpha$  will gives us value  $a$ . So once we know the value of  $a$  and  $b$  we can compute  $\epsilon_x$  and  $\gamma_{x \text{ prime } y \text{ prime}}$ . Now let us compute the values of  $a$  and  $b$ .

(Refer Slide Time: 52:11)

Handwritten calculations on a whiteboard:

$$a = R \sin 22^\circ$$

$$= 146 \times 10^{-6} \sin 22^\circ = -54.7 \times 10^{-6}$$

$$\gamma_{xy}' = -109.4 \times 10^{-6}$$

$$b = R \cos 22^\circ$$

$$= 146 \times 10^{-6} \cos 22^\circ = 135.37 \times 10^{-6}$$

$$\epsilon_{x'} = (225 + 135.37) \times 10^{-6} = \dots$$

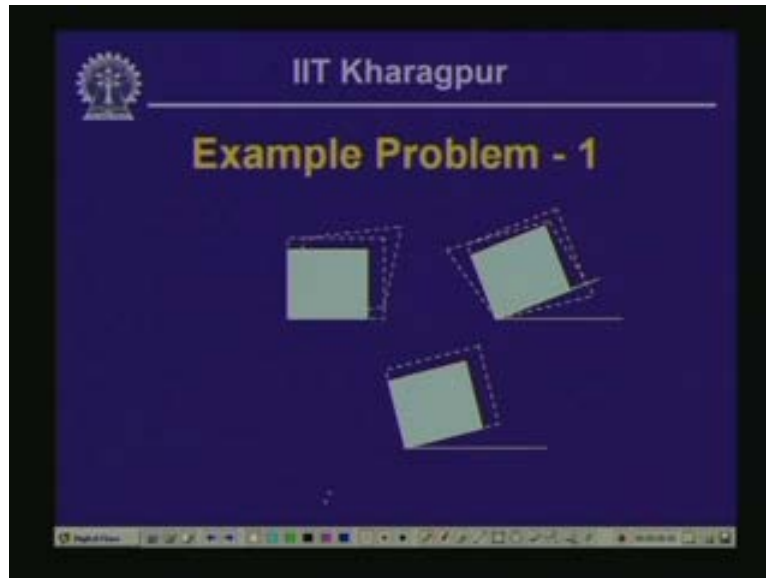

$$\epsilon_{y'} = 89.65 \times 10^{-6}$$

$$\text{Max Shear Strain} = 2 \times 146 \times 10^{-6}$$

Now  $a$  is equal to  $R \sin 22$  degrees is equal to  $146$  ( $10$  to the power minus  $6$ ) ( $\sin 22$  degrees) is equal to minus  $54.7$   $10$  to the power minus  $6$  and writing this as a minus because it is in the negative direction. So  $\gamma_{xy}'$  in fact the shearing strain is twice of this so minus  $109.4$  ( $10$  to the power minus  $6$ ) is the shearing strain. Now the distance  $b$  is equal to  $R \cos 22$  degrees is equal to  $146$  ( $10$  to the power minus  $6$ )  $\cos 22$  degrees is equal to  $135.37$  ( $10$  to the power minus  $6$ ). So  $\epsilon_{x'}$  is equal to  $225$  plus  $135.37$  ( $10$  to the power minus  $6$ ) the normal strain and  $\epsilon_{y'}$  consequently will be the minus of this which is diametrically opposite is equal to  $89.65$  ( $10$  to the power minus  $6$ ) and  $\gamma_{xy}$  is equal to this. So these are the values of the strain and maximum shear strain is equal to the radius of the Mohr circle is equal to  $2(146)$ ;  $\frac{\gamma}{2}$  is the radius so  $2(146)$  ( $10$  to the power minus  $6$ ) is equal to  $292$  ( $10$  to the power minus  $6$ ). These are the values of the strain quantities.

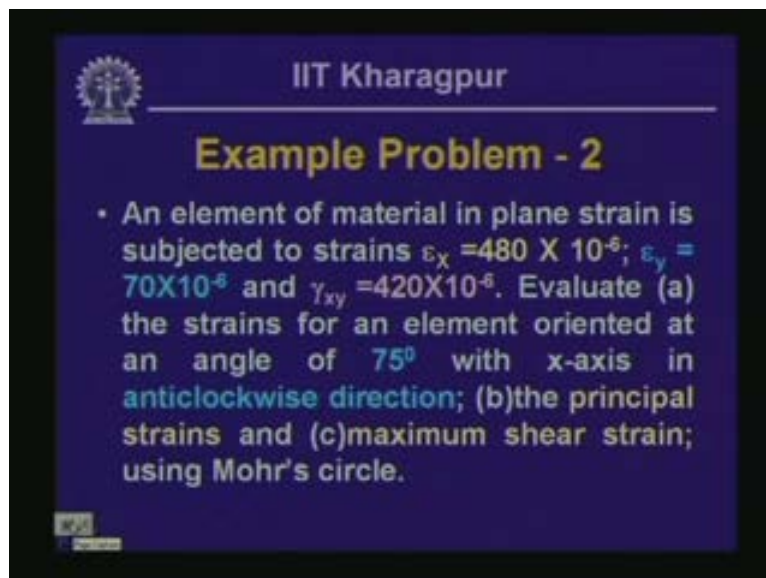

(Refer Slide Time: 53:29)

Once this particular element undergoes strains now this is the configuration which we expect. In the initial stages we have  $\epsilon_x$  as 340 and  $\epsilon_y$  as 110 and we had the positive shear which is denoted by this as 180 and we had the orientation of the element as the initial strain. Finally when it is rotated at an angle of 30 degrees, it has  $\epsilon_{x'}$ ,  $\epsilon_{y'}$  and  $\gamma_{x'y'}$  is negative so the angle here increases and this is the form which it takes. This is the final shape of the body after it has undergone the strain. And when it undergoes the principal strain, the principal strain direction is 19 degrees. This is the direction of  $\epsilon_1$  and this is the direction of  $\epsilon_2$  and both are positive and here there is no shearing strain.

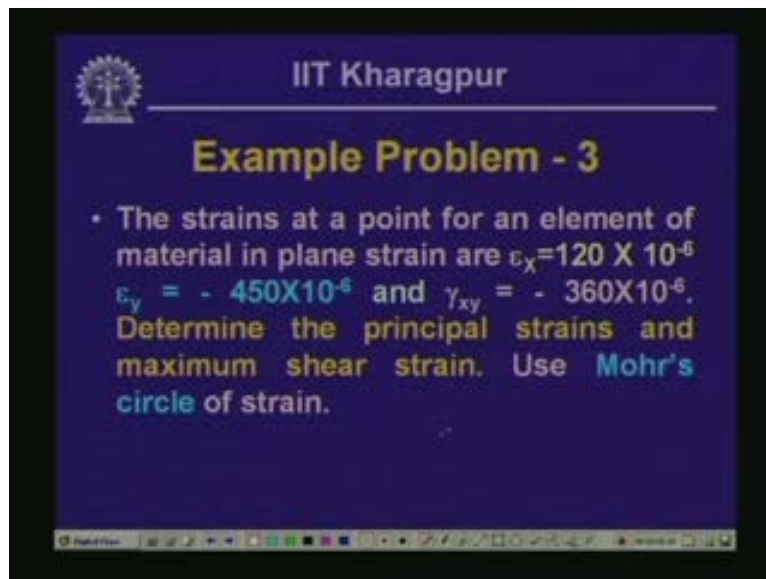

(Refer Slide Time: 53:37)

Hence this would be the shape. We have another example which is similar type that any element a material in plane strain is subjected to strains  $\epsilon_x$  is 48 (10 to the power minus 6);  $\epsilon_y$  is 70 (10 to the power minus 6);  $\gamma_{xy}$  is 420 (10 to the power minus 6). Let us evaluate the strain at an element which is oriented at an angle of 75 degrees with x -axis in

anticlockwise direction and the principal strains and the maximum shear strain using Mohr's circle.

(Refer Slide Time: 54:24)

The slide features the IIT Kharagpur logo in the top left corner. The title "IIT Kharagpur" is centered at the top. Below it, "Example Problem - 3" is written in a large, bold, yellow font. The main text, in white, describes a plane strain problem with given values for  $\epsilon_x$ ,  $\epsilon_y$ , and  $\gamma_{xy}$ . The text concludes with the instruction to use Mohr's circle of strain.

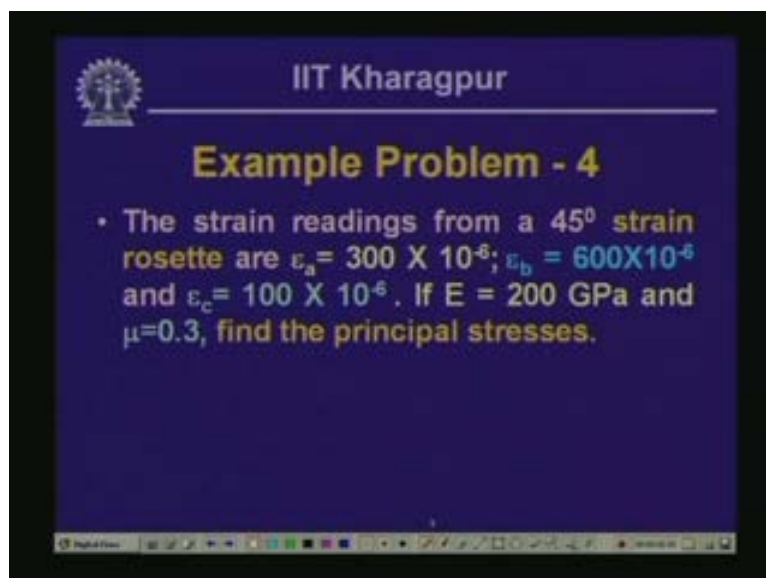

IIT Kharagpur

### Example Problem - 3

- The strains at a point for an element of material in plane strain are  $\epsilon_x = 120 \times 10^{-6}$ ,  $\epsilon_y = -450 \times 10^{-6}$  and  $\gamma_{xy} = -360 \times 10^{-6}$ . Determine the principal strains and maximum shear strain. Use Mohr's circle of strain.

Here is another example wherein this is also identical. We have  $\epsilon_x$ ,  $\epsilon_y$  and  $\gamma_{xy}$ . The strains at a point for an element of material in plane strain are of this form where  $\epsilon_x$  is 120 (10 to the power minus 6) which is positive  $\epsilon_y$  is negative is minus 450 (10 to the power minus 6) and the shearing strain also negative minus 360 (10 to the power minus 6). We will have to determine the principal strains and the maximum shear strain using Mohr circular strain. This is also being similar to the previous problem. Now let us look into this particular problem.

(Refer Slide Time: 55:11)

The slide features the IIT Kharagpur logo in the top left corner. The title "IIT Kharagpur" is centered at the top. Below it, "Example Problem - 4" is written in a large, bold, yellow font. The main text, in white, describes a problem involving a 45-degree strain rosette with given strain readings  $\epsilon_a$ ,  $\epsilon_b$ , and  $\epsilon_c$ , and material properties  $E$  and  $\mu$ . The text concludes with the instruction to find the principal stresses.

IIT Kharagpur

### Example Problem - 4

- The strain readings from a  $45^\circ$  strain rosette are  $\epsilon_a = 300 \times 10^{-6}$ ;  $\epsilon_b = 600 \times 10^{-6}$  and  $\epsilon_c = 100 \times 10^{-6}$ . If  $E = 200$  GPa and  $\mu = 0.3$ , find the principal stresses.

It is based on the aspects we have discussed where the strain readings from a 45 degrees strain rosette are  $\epsilon_a$  is this much,  $\epsilon_b$  is this much, and  $\epsilon_c$  is this much, so if  $E$  is equal to 200 GPa and  $\mu$  is equal to 0.3 what will be the values of the principal stresses.

(Refer Slide Time: 59:34)

The image shows two handwritten equations on a whiteboard. The first equation is  $\epsilon_1 = \frac{\sigma_1}{E} - \frac{\mu\sigma_2}{E}$  and the second equation is  $\epsilon_2 = \frac{\sigma_2}{E} - \frac{\mu\sigma_1}{E}$ . Both equations are marked with checkmarks.

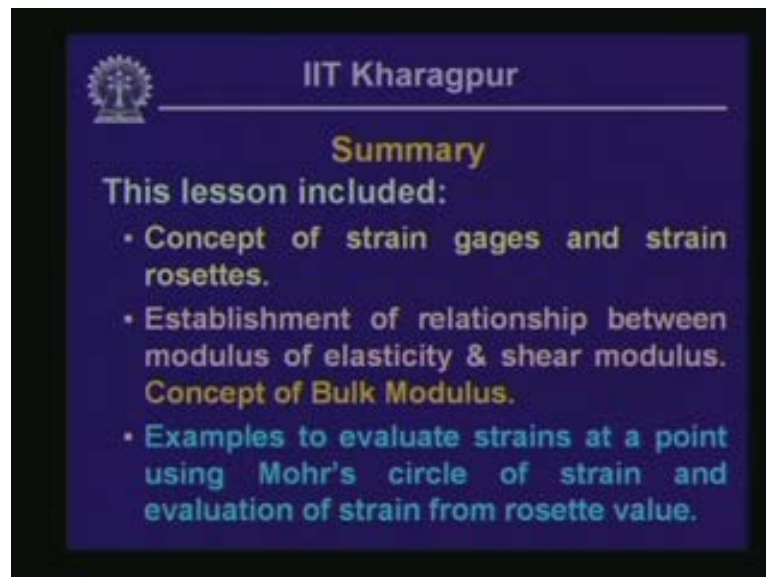

Now as we have seen that we have rosettes which are oriented in three different directions this is  $\epsilon_a$ , this is  $\epsilon_b$ , and this is  $\epsilon_c$ ; and as you have seen that  $\epsilon_x$  is equal to  $\epsilon_a$  and  $\epsilon_y$  is equal to  $\epsilon_c$  and  $\frac{\gamma_{xy}}{2}$  is equal to  $\epsilon_b$  minus  $\epsilon_a$  plus  $\epsilon_c$  by 2. Now from this we can get the values of  $\epsilon_x$ ,  $\epsilon_y$ , and  $\gamma_{xy}$  and we can compute the values of the stresses.

The values of  $\epsilon_a$  is equal to 300 (10 to the power minus 6),  $\epsilon_b$  is equal to 600 (10 to the power minus 6), and  $\epsilon_c$  is 100 (10 to the power minus 6)  $\frac{\gamma_{xy}}{2}$  is equal to 600 minus 300 plus 100 by 2 (10 to the power minus 6) is equal to 400 (10 to the power minus 6). If we plot these in a Mohr circle with the values of  $\epsilon_a$  is  $\epsilon_x$  and  $\epsilon_c$  is  $\epsilon_y$  this is  $\epsilon$  axis and this is the  $\gamma_{xy}$  axis.

We have  $\epsilon_x$  as 300 and  $\frac{\gamma_{xy}}{2}$  is equal to 400. We have  $\epsilon_y$  as 100 and  $\gamma$  by 2 is 400 and if we join this together we get the center and if we plot the circle we get the Mohr circle of strain and this is the value which is  $\epsilon_1$  and this is the value which is  $\epsilon_2$ . Now this distance is equal to  $\epsilon_x$  plus  $\epsilon_y$  by 2 300 plus 100 is equal to 400 by 2 is equal to 200 and this distance  $\epsilon_x$  minus  $\epsilon_y$  by 2 which is 300 minus 100 is equal to 200 by 2 is equal to 100 and this distance is 400. So  $R$  is equal to  $\sqrt{(100^2) + 400^2} (10^{-6})$ . We have and this is equal to 412.3 (10 to the power minus 6). Hence the value of  $\epsilon_1$  is equal to this distance plus the radius and this distance is equal to 200 so 200 plus 412 is equal to 612.

Consequently  $\epsilon_2$  is this distance minus the radius so this is negative which is  $200 - 412$  ( $10$  to the power minus  $6$ ) is equal to minus  $212$  ( $10$  to the power minus  $6$ ) so that is the value of  $\epsilon_2$ . Hence once we have the value of  $\epsilon_1$  and  $\epsilon_2$ , as you know the value of  $\epsilon_1$  is equal to  $\sigma_1$  by  $E$  minus  $\mu \sigma_2$  by  $E$  and consequently  $\epsilon_2$  is equal to  $\sigma_2$  by  $E$  minus  $\mu \sigma_1$  by  $E$ . Now from this if we substitute the value of  $\epsilon_1$  and  $\epsilon_2$  we can get the value of  $\sigma_1$  and  $\sigma_2$ .

IIT Kharagpur

**Summary**

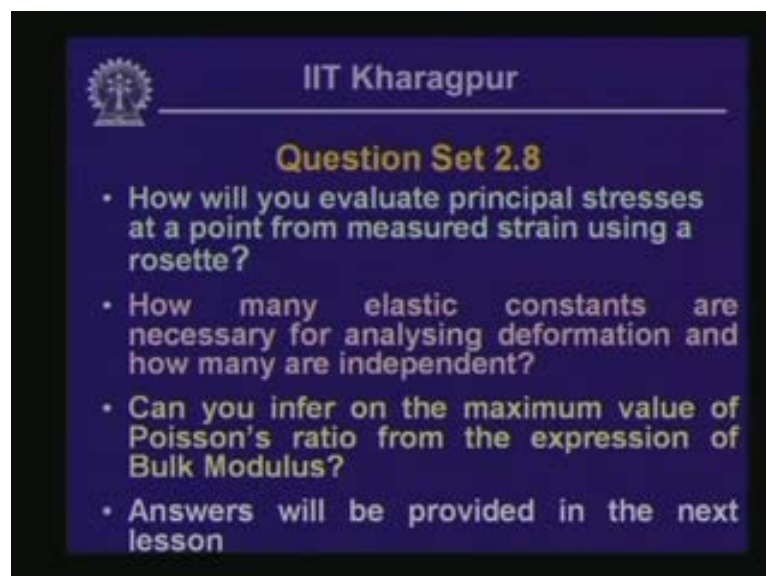

This lesson included:

- Concept of strain gages and strain rosettes.
- Establishment of relationship between modulus of elasticity & shear modulus. **Concept of Bulk Modulus.**
- Examples to evaluate strains at a point using Mohr's circle of strain and evaluation of strain from rosette value.

Summary:

In this particular lesson we have included the concept of strain gages and strain rosettes, and some of the relationships between the elastic **modulae**.

(Refer Slide Time: 59:47)

The slide features the IIT Kharagpur logo in the top left corner. The text is centered and includes a title and a bulleted list of questions.

IIT Kharagpur

**Question Set 2.8**

- How will you evaluate principal stresses at a point from measured strain using a rosette?
- How many elastic constants are necessary for analysing deformation and how many are independent?
- Can you infer on the maximum value of Poisson's ratio from the expression of Bulk Modulus?
- Answers will be provided in the next lesson
