**Application of Stress by Strain**  
**Thin-walled Pressure Vessels - I**

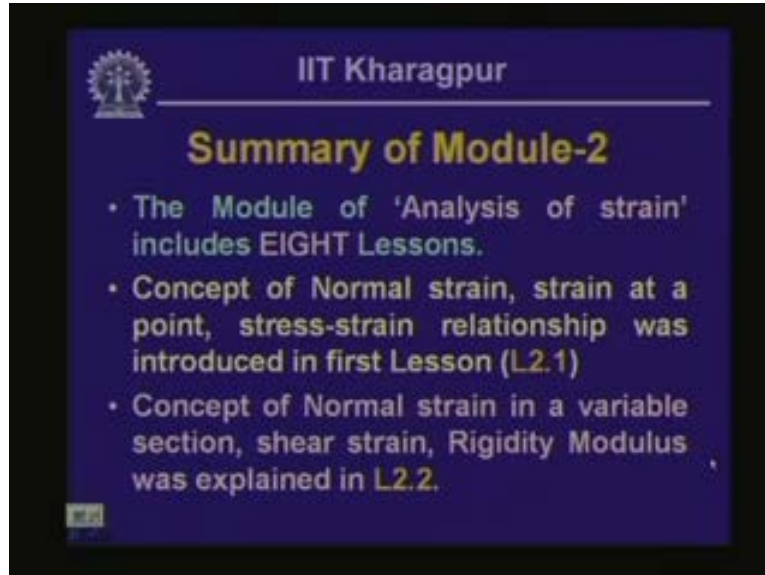

Welcome to the first lesson of third module which is on thin-walled pressure vessels part one which is on the application of stress and strain.

(Refer Slide Time: 00:45)

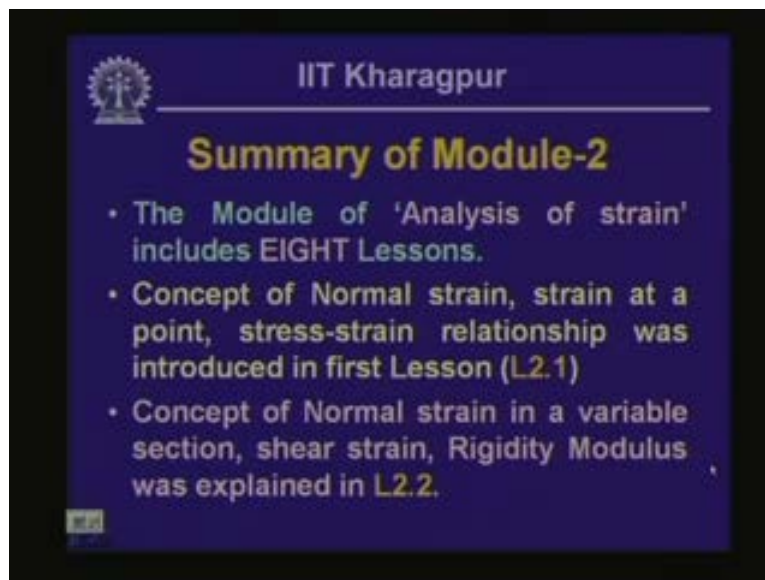

In the last two modules 1 and 2 we had looked into the aspects of analysis of stress and analysis of strain at a point in a stress body as to how we compute the stresses and strain? Now we will look into the applications of this stress and strains at a point in thin-walled pressure vessels. The pressure vessel has wide industrial applications. In many industries we use this kind of vessel where the pressurized air or water is used. It is necessary to evaluate the strains and the stresses at any point on the surface of pressure vessels. We will also look into how to compute the strains and stresses on the body of such pressure vessels.

(Refer Slide Time: 1:30)

Before we go into the analysis of pressure vessels let us look into aspects which we discussed in the last module. Module-2 was devoted to on analysis of strain and we had 8 lessons, so let us quickly look into those lessons which we covered in Module-2.

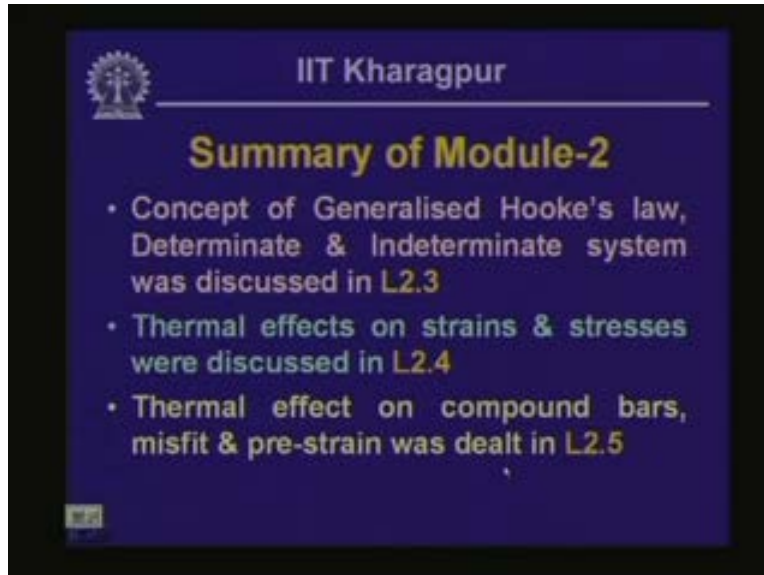

(Refer Slide Time: 2:10)

The module of analysis of strain includes 8 lessons. The 1st lesson was on the concept of normal strain, the strain at a point and stress strain relationship. The 2nd lesson was devoted to the aspect of normal strain in a variable section. In the first lesson we discussed the normal strain in a uniform body. If the body is having a variable section then what will be the strain in that and

correspondingly the shearing strain in that. We also discussed the concept of rigidity modulus in the second lesson.

(Refer Slide Time: 2:45)

The slide features the IIT Kharagpur logo in the top left corner and the text "IIT Kharagpur" at the top center. Below this is the title "Summary of Module-2" in a large, bold, yellow font. The main content is a bulleted list of three items, each followed by a lesson number in yellow. The background is a solid blue color.

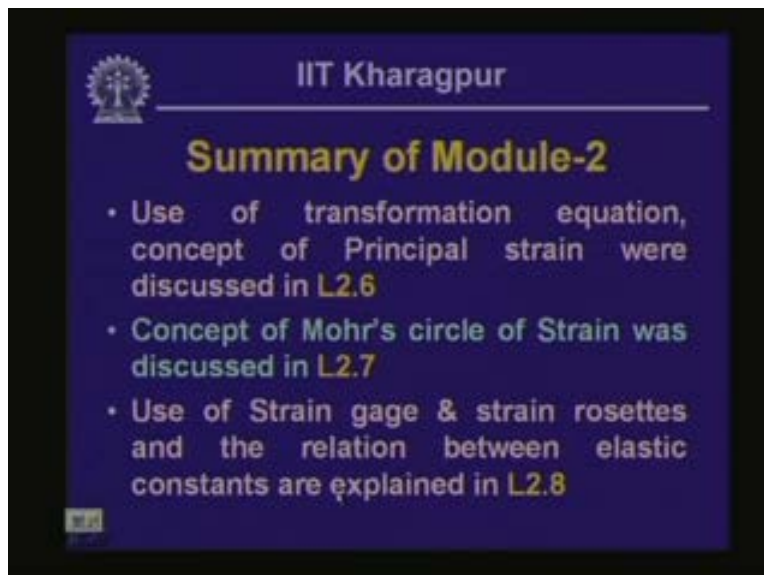

IIT Kharagpur

### Summary of Module-2

- Concept of Generalised Hooke's law, Determinate & Indeterminate system was discussed in L2.3
- Thermal effects on strains & stresses were discussed in L2.4
- Thermal effect on compound bars, misfit & pre-strain was dealt in L2.5

In the 3rd lesson we had introduced the concept of generalized Hooke's law and the determinate and indeterminate system were discussed. Thermal effects on strains and stresses were discussed in Module-2 and the fourth lesson. Thermal effect on compound bars and the misfit and correspondingly the pre-strain and pre-stresses was dealt with in the 5th lesson of Module-2.

### Summary of Module-2

- Use of transformation equation, concept of Principal strain were discussed in L2.6
- Concept of Mohr's circle of Strain was discussed in L2.7
- Use of Strain gage & strain rosettes and the relation between elastic constants are explained in L2.8

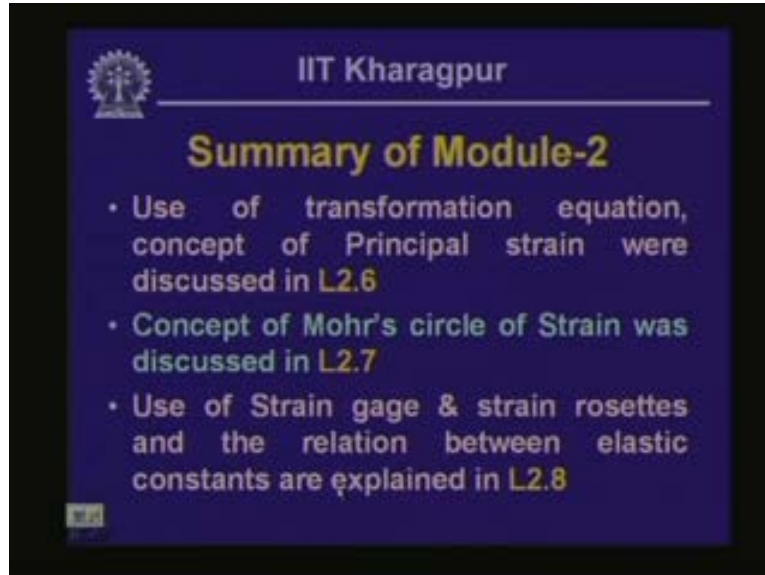

In the 6th lesson we discussed the transformation equation and we had discussed this aspect in the first module of stress as well wherein we say, at a particular point if you are interested to compute the values of stress and thereby the strains then we need to use the transformation equation if we orient the axes system from the rectangular axes system.

(Refer Slide Time: 3:40)

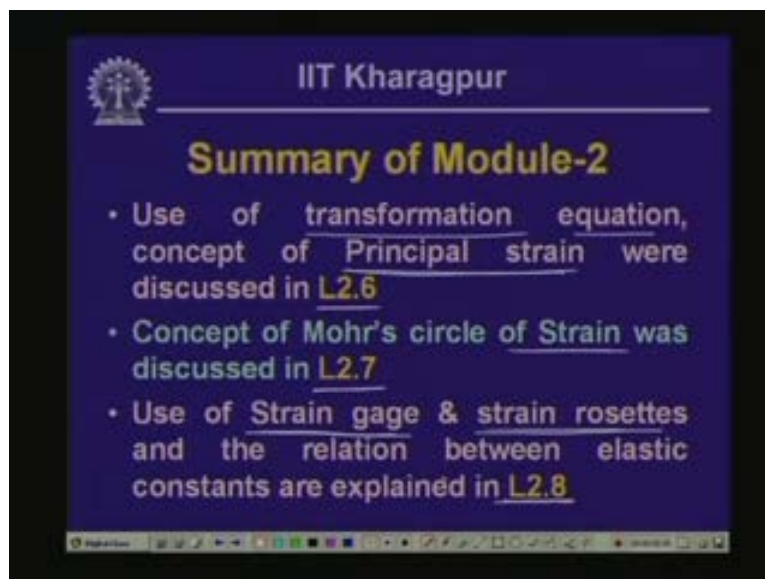

That is what was discussed in Module-2 lesson 6 in 2.6 where we had introduced the concept of transformation equation and thereby how to evaluate the principal strain. Then we saw the concept of Mohr's circle of strain, how to compute the strain at different orientations at that particular point where we know the rectangular strain components  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  how to compute the values of principal strain and strain at that particular point at different orientations. If you like to compute we can do it through the use of Mohr's circle of strain and that is what was discussed in lesson 7.

(Refer Slide Time: 4:15)

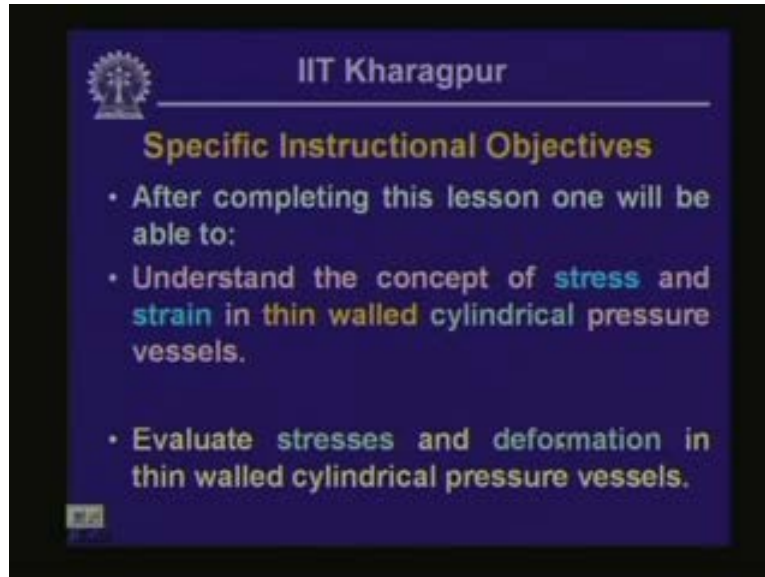

In the 8th lesson we introduced the concept of strain gage and strain rosettes. Thereby at any point it is easier to measure the strain and it is difficult to measure the stresses at any point when we talk about a stress body. We can measure the strains and thereby from those measures of strains we compute the stresses but as we have seen we measure the strains in the normal direction as the normal strain. Therefore out of three strain components  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  it is very difficult to measure  $\gamma_{xy}$  the shearing strain. Hence we take an indirect way to measure  $\gamma_{xy}$  by using strain gages in three directions which we have called as strain rosettes. From the measured data of strain rosettes, we can compute the strains of  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$ . Using these strain components we can compute the principal strains and thereby the principal stresses.

(Refer Slide Time: 6:30)

This is what was discussed in lesson 8 Module-2. Also, we looked into the relationship between the elastic constants which were  $E$ ,  $G$  and  $\mu$ .

(Refer Slide Time: 6:50)

This is the summarization of the Module-2. It is expected that once this particular lesson is completed, one should be able to understand the concept of stress and strain in thin-walled cylindrical pressure vessels. Here we are concerned with two aspects, one is the vessel is subjected to internal pressure and this internal pressure is over and above the external pressure by overcoming the external pressure on the vessel the internal pressure is working and thereby there will be the stresses generated in the vessel and we are interested in evaluating those stresses.

Secondly, this is a thin-walled structure and this means that the thickness of the wall is very small so that the stress variation across the thickness is significantly small or we neglect that. Hence the thin-walled pressure vessel is of importance and we will look into how to compute the stresses in such vessels.

(Refer Slide Time: 7:22)

IIT Kharagpur

### Specific Instructional Objectives

- After completing this lesson one will be able to:
- Understand the concept of **stress** and **strain** in **thin walled** cylindrical pressure vessels.
- Evaluate **stresses** and **deformation** in **thin walled** cylindrical pressure vessels.

7:22

Thereby we will evaluate stresses and deformation in the thin-walled cylindrical pressure vessels subjected to internal pressure because of the content in the container.

(Refer Slide Time: 7:37)

IIT Kharagpur

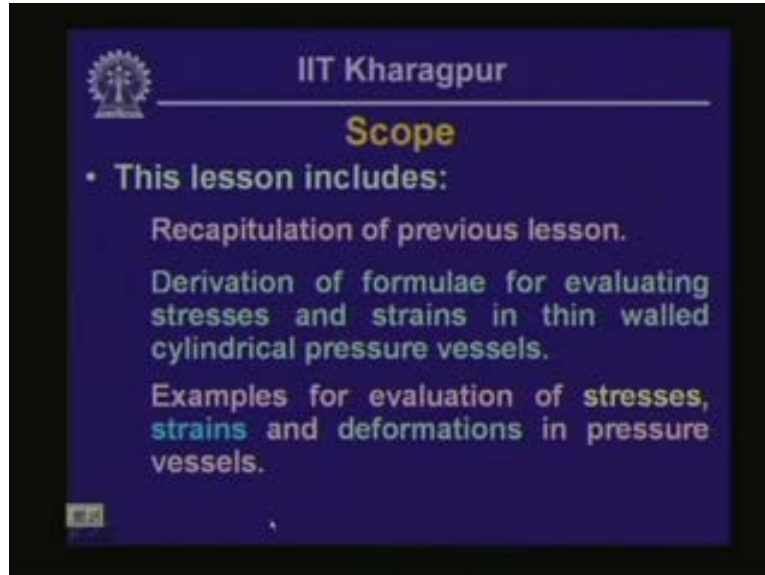

### Scope

- This lesson includes:
  - Recapitulation of previous lesson.
  - Derivation of formulae for evaluating **stresses** and **strains** in **thin walled** cylindrical pressure vessels.
  - Examples for evaluation of **stresses**, **strains** and **deformations** in pressure vessels.

7:37

As we keep going through we will be looking into the aspects of previous lessons or recapitulation of previous lessons which we will be doing through the question answer session. We will look into the answers for those questions which I had posed for you in the last lesson and thereby will be scanning through the aspects which we had discussed in the previous lesson.

(Refer Slide Time: 8:04)

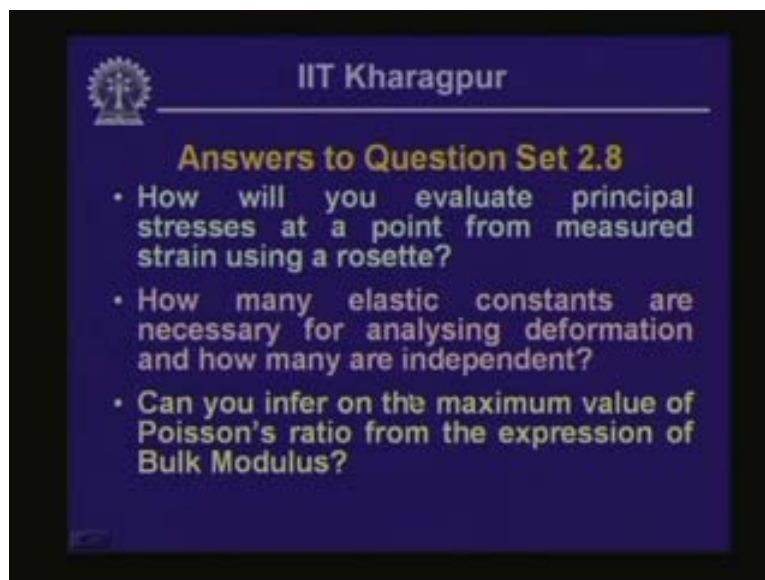

IIT Kharagpur

### Scope

- This lesson includes:
  - Recapitulation of previous lesson.
  - Derivation of formulae for evaluating stresses and strains in thin walled cylindrical pressure vessels.
  - Examples for evaluation of stresses, strains and deformations in pressure vessels.

Also, we are going to derive the formulae for evaluating stresses and strains in thin-walled cylindrical pressure vessels. In this particular lesson we will be concentrating on the cylindrical type of pressure vessels and subsequently we look into different categories of pressure vessels. We will also look through a few examples for evaluation of stresses, strains and deformations in such pressure vessels. These are the two main aspects that we will be doing in this particular lesson.

(Refer Slide Time: 8:38)

IIT Kharagpur

### Answers to Question Set 2.8

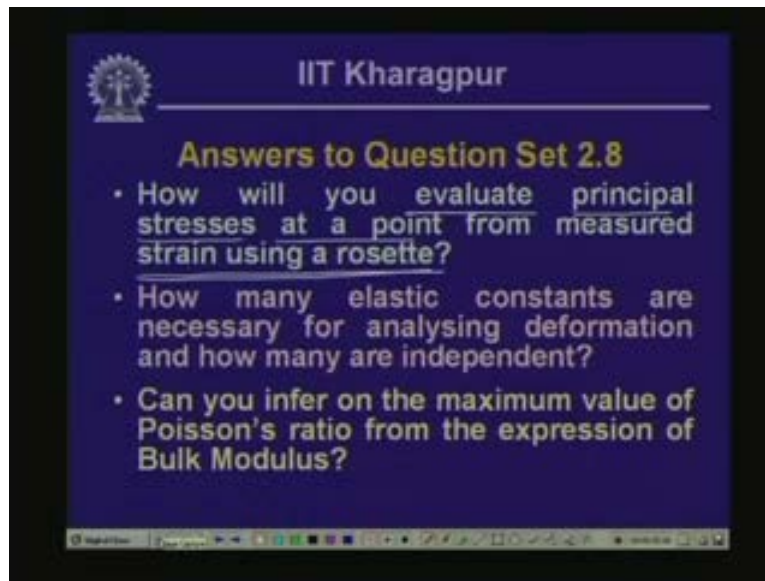

- How will you evaluate principal stresses at a point from measured strain using a rosette?
- How many elastic constants are necessary for analysing deformation and how many are independent?
- Can you infer on the maximum value of Poisson's ratio from the expression of Bulk Modulus?

Let us look into the answers to this questions which I posed last time. The first question is how you will evaluate principal stresses at a point from measured strain using a rosette. When we try

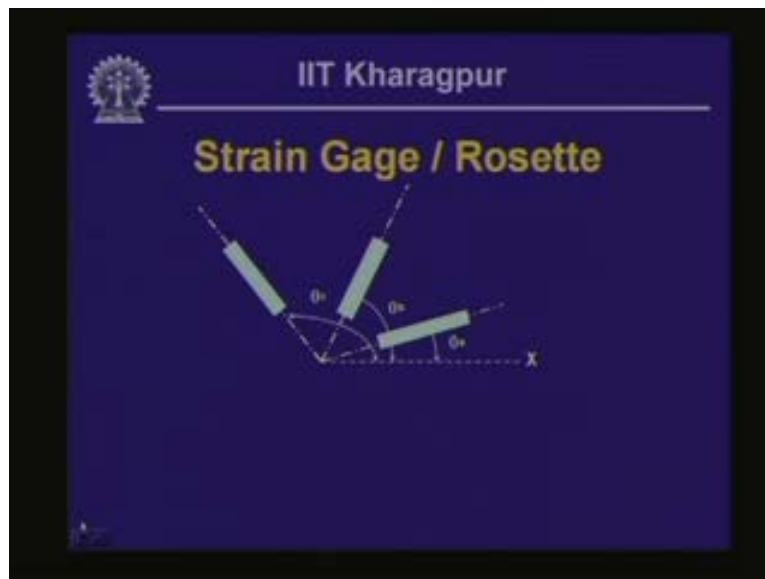

to measure stress at a point we cannot directly measure the stress. Hence we measure strain at that particular point and thereby we compute the values of stresses. The strain component as we have  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  under a plane strain situation we cannot measure  $\gamma_{xy}$  directly, instead we measure indirectly and from there we compute the values of principal strains. Now let us look into how that is done.

(Refer Slide Time: 9:31)

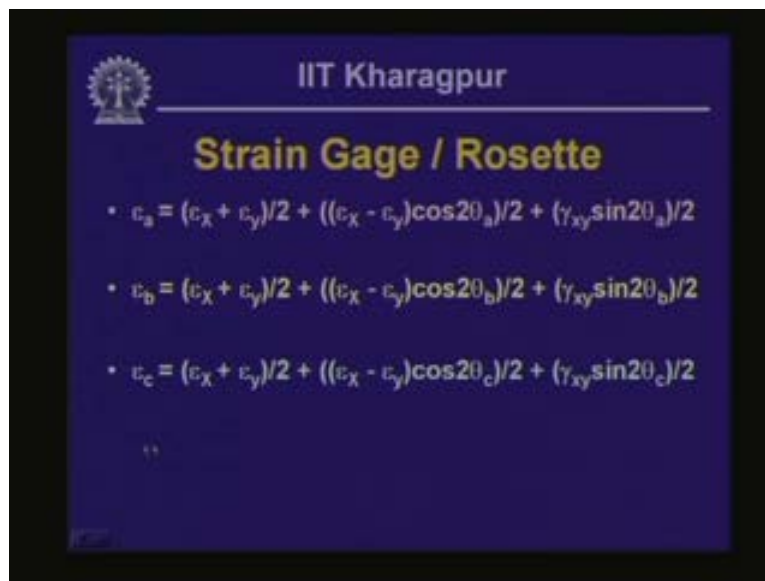

(Refer Slide Time: 9:34)

In the previous lesson we had discussed that this is the x direction and this is the y direction. We can use these kinds of strain gages which can measure the normal strain. If we place these types of gages in the x direction and y direction we can measure the strain  $\epsilon_x$ ,  $\epsilon_y$ , but we need three

quantities  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  for evaluating the principal strains. Since we cannot measure  $\gamma_{xy}$  directly what we do is that we place three strain gages in three different orientations. Let us call this direction as a, this as b and this as c. All three are oriented at three different angles; this particular angle is  $\theta_a$ , this angle in the second gage which is along the b is at an angle of  $\theta_b$  and the third gage which is along c is oriented at an angle of  $\theta_c$ . And thereby employing the transformation equation which is:  $\epsilon_{x'}$  is equal to  $\epsilon_x \cos^2\theta + \epsilon_y \sin^2\theta + \frac{\gamma_{xy}}{2} \sin 2\theta$  is the transformation equation. We can employ this equation to evaluate strain along a, b and c which are  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$ . Keeping in mind that  $\epsilon_x$  is acting along x which is at an orientation with reference to x axis at an angle of  $\theta_a$  hence in the place of  $\theta$  we will substitute  $\theta_a$  and for  $\epsilon_b$  the orientation is along  $\theta_b$  and for  $\epsilon_c$  the orientation is along  $\theta_c$ .

(Refer Slide Time: 12:20)

So, if we substitute that we can get the equations in this particular form where we have three equations  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  and they are oriented at an angle of  $\theta_a$ ,  $\theta_b$  and  $\theta_c$ . In these three equations if we look we know  $\epsilon_a$ ,  $\epsilon_b$ , we know  $\epsilon_c$ . Also, we know  $\theta_a$ ,  $\theta_b$ ,  $\theta_c$  as these are predetermined orientations that gages along which it will be placed  $\theta_a$ ,  $\theta_b$ ,  $\theta_c$  are predetermined hence  $\theta_a$ ,  $\theta_b$ ,  $\theta_c$  are known. And since we are measuring strain along a, b and c so  $\epsilon_a$ ,  $\epsilon_b$  and  $\epsilon_c$  are known.

(Refer Slide Time: 12:45)

IIT Kharagpur

### Strain Gage / Rosette

- $\epsilon_a = (\epsilon_x + \epsilon_y)/2 + ((\epsilon_x - \epsilon_y)\cos 2\theta_a)/2 + (\gamma_{xy}\sin 2\theta_a)/2$
- $\epsilon_b = (\epsilon_x + \epsilon_y)/2 + ((\epsilon_x - \epsilon_y)\cos 2\theta_b)/2 + (\gamma_{xy}\sin 2\theta_b)/2$
- $\epsilon_c = (\epsilon_x + \epsilon_y)/2 + ((\epsilon_x - \epsilon_y)\cos 2\theta_c)/2 + (\gamma_{xy}\sin 2\theta_c)/2$

So in these three equations six quantities are known so the only unknown quantities are  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  which we can evaluate from these three equations. Once we know  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  now we can compute the values of  $\epsilon_1$  and  $\epsilon_2$ . We can compute as a function of  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$  which is  $(\epsilon_x, \epsilon_y)$  whole square plus  $\sqrt{(\epsilon_x - \epsilon_y)^2 + (\gamma_{xy})^2}$  plus  $(\epsilon_x + \epsilon_y)$  whole square. So this is the value of maximum principal strength and same quantity with minus will give the quantity of  $\epsilon_2$ . So we can evaluate the value of  $\epsilon_1$  and  $\epsilon_2$  from  $\epsilon_x$ ,  $\epsilon_y$ ,  $\gamma_{xy}$ . We computed the values of strain in terms of stresses and there  $E\epsilon_1$  is equal to  $\sigma_1$  by  $E$  -  $\mu\sigma_2$  by  $E$  where  $\sigma_1$  and  $\sigma_2$  are the principal stresses and  $\epsilon_1$  and  $\epsilon_2$  are the principal strain and  $\sigma_1$  and  $\sigma_2$  are the principal stresses. And as we know the direction of principal stresses and direction of principal strain coincides.

(Refer Slide Time: 14:06)

The image shows handwritten mathematical derivations on a whiteboard. The equations are as follows:

$$\underline{\underline{\epsilon_1}} = \frac{\epsilon_x + \epsilon_y}{2} + \sqrt{\left(\frac{\epsilon_x - \epsilon_y}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2}$$

$$\underline{\underline{\epsilon_2}} = \frac{\epsilon_x + \epsilon_y}{2} - \sqrt{\left(\frac{\epsilon_x - \epsilon_y}{2}\right)^2 + \left(\frac{\gamma_{xy}}{2}\right)^2}$$

$$\epsilon_1 = \frac{\sigma_1}{E} - \frac{\mu \sigma_2}{E} \quad \text{--- (1)}$$

$$\epsilon_2 = \frac{\sigma_2}{E} - \frac{\mu \sigma_1}{E} \quad \text{--- (2)}$$

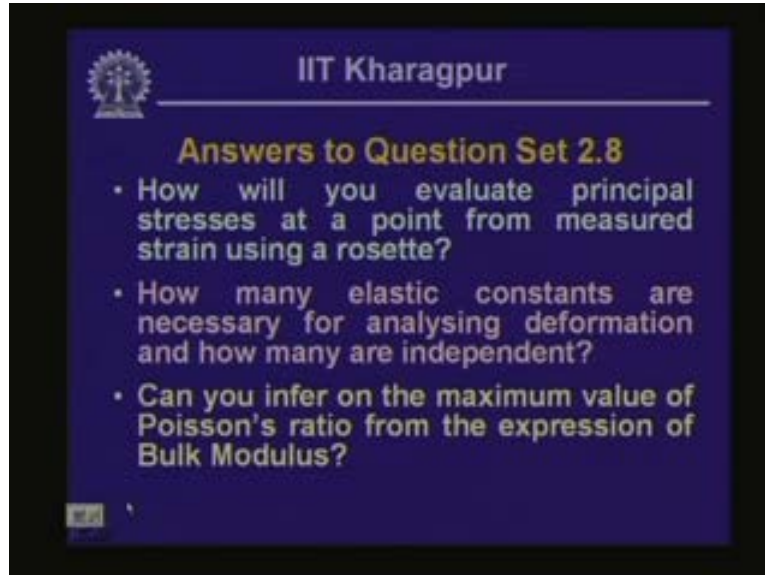

$$\epsilon_1 + \mu \epsilon_2 = \frac{\sigma_1}{E} - \frac{\mu^2 \sigma_1}{E}$$

$$\underline{\underline{\sigma_1}} = \frac{E}{(1 - \mu^2)} (\epsilon_1 + \mu \epsilon_2)$$

So we can compute the values of principal strain from the principal stresses in this form and likewise  $\epsilon_2$  the strain in the minimum strain direction is equal to  $\sigma_2$  by  $E$  minus  $\mu \sigma_1$  by  $E$ . If we multiply the second part of this equation with  $\mu$  and add of with the first one we get  $\epsilon_1$  plus  $\mu \star \epsilon_2$  is equal to  $\sigma_1$  by  $E$ .

Now this minus  $\mu \sigma$  by  $E$  and this is  $\sigma_2$  by  $E$  and when it is multiplied with  $\mu$  this gets cancelled so we have minus  $\mu$  square  $\sigma_1$  star  $e$  or this is equal to  $1$  minus  $\mu$  square star  $e$  star  $\sigma_1$ . From this we get the value of  $\sigma_1$  is equal to  $E$  by  $(1 - \mu)$  whole square  $(\epsilon_1$  plus  $\mu \epsilon_2)$ . So this is the value of  $\sigma_1$  in terms of  $\epsilon_1$  and  $\epsilon_2$  and  $\epsilon_1, \epsilon_2$  we have obtained in terms of  $\epsilon_x, \epsilon_y, \gamma_{xy}$ . So once we measure strains along three directions we can compute  $\epsilon_x, \epsilon_y, \gamma_{xy}$  and from those measured values of  $\epsilon_x$  or evaluated values of  $\epsilon_x, \epsilon_y, \gamma_{xy}$  we can compute  $\epsilon_1$  and  $\epsilon_2$  and once we know  $\epsilon_1, \epsilon_2$ . We can find out stress  $\sigma_1$  likewise stress  $\sigma_2$  stress is equal to  $E$  by  $(1 - \mu)$  whole square  $(\epsilon_2$  plus  $\mu \epsilon_1)$ . So these are the values of the principal stresses  $\sigma_1$  and  $\sigma_2$ .

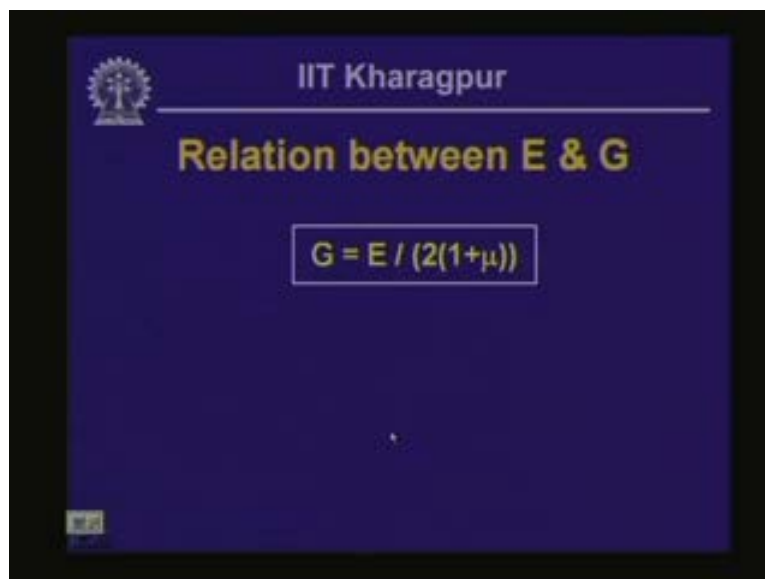

(Refer Slide Time: 16:23)

How will you evaluate principal stresses at a point from measured strain using a rosette?

This is how from the measured strain data we can compute the values of principal stresses which is  $\sigma_1$  and  $\sigma_2$ . Let us look into the second question. How many elastic constants are necessary for analyzing deformation and how many are independent?

(Refer Slide Time: 16:48)

Now we have seen that when we are trying to compute the stresses and the strains we are requiring three constants which are E, G and  $\mu$ . The modulus of elasticity is E and G is the shear modulus and  $\mu$  is the Poisson's ratio. As we have seen last time when we were relating to shear modulus with elastic modulus out of these three constants; E, G and  $\mu$  which are

necessary for analyzing deformation in a stress body two are independent and in fact G can be evaluated once we know the value of e and mu. So, out of these three elastic constants two are independent and one is dependent on the other two. This is what is demonstrated here that G is equal to E by 2(1 plus mu) as we derived last time. Once we know the value of E and mu we can get the value of G. Though we need these three constants the two are independent.

(Refer Slide Time: 17:57)

### Answers to Question Set 2.8

- How will you evaluate principal stresses at a point from measured strain using a rosette?
- How many elastic constants are necessary for analysing deformation and how many are independent?
- Can you infer on the maximum value of Poisson's ratio from the expression of Bulk Modulus?

The third question is can you infer on the maximum value of Poisson's ratio from the expression of bulk modulus?

(Refer Slide Time: 18:14)

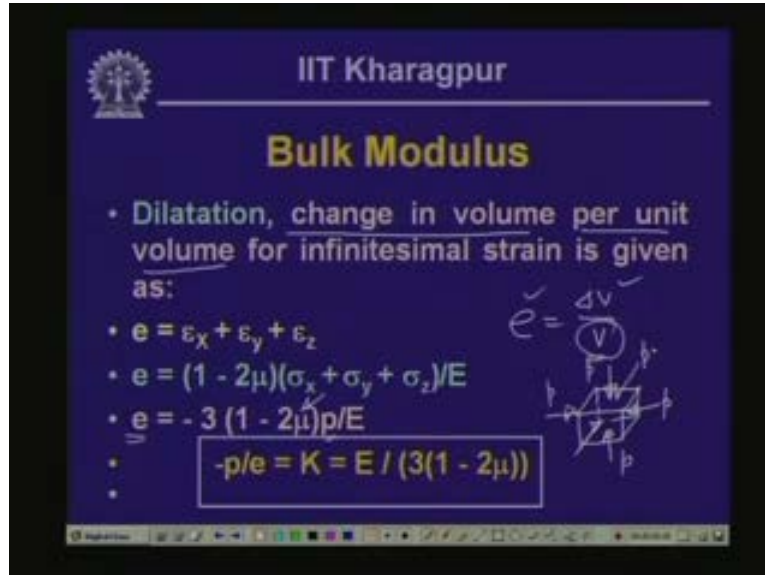

IIT Kharagpur

## Bulk Modulus

- Dilatation, change in volume per unit volume for infinitesimal strain is given as:
- $e = \epsilon_x + \epsilon_y + \epsilon_z$
- $e = (1 - 2\mu)(\sigma_x + \sigma_y + \sigma_z)/E$
- $e = -3(1 - 2\mu)p/E$
- $-p/e = K = E / (3(1 - 2\mu))$

Let us look into the bulk modulus. Dilatation which we have denoted as  $e$  is defined as  $\Delta_v$  by  $v$  where  $\Delta_v$  is the change in the volume and  $V$  is the original volume and that is how we say that the dilatation is the change in volume per unit volume. If this is equal to 1 then  $E$  is equal to  $\Delta v$ . Now in the expression for the change in volume or the dilatation we have the Poisson's ratio  $\mu$ . There is another term here which is  $p$ , and  $e$  you are already acquainted with which is elastic modulus and  $p$  is the term which is the hydrostatic pressure acting at that particular point in the small element. Now  $p$  is the stress quantity which is acting in all directions in place of  $\sigma_x$ ,  $\sigma_y$  and  $\sigma_z$ . These are the values of  $p$  which are called as the state of hydrostatic pressure. That means that element is subjected to a compressive stress from all sides and it is under the state of a compressive force.

(Refer Slide Time: 19:35)

The slide is from IIT Kharagpur and is titled "Bulk Modulus". It contains the following text and equations:

- Dilatation, change in volume per unit volume for infinitesimal strain is given as:
- $e = \epsilon_x + \epsilon_y + \epsilon_z$
- $e = (1 - 2\mu)(\sigma_x + \sigma_y + \sigma_z)/E$
- $e = -3(1 - 2\mu)p/E$
- $-p/e = K = E / (3(1 - 2\mu))$

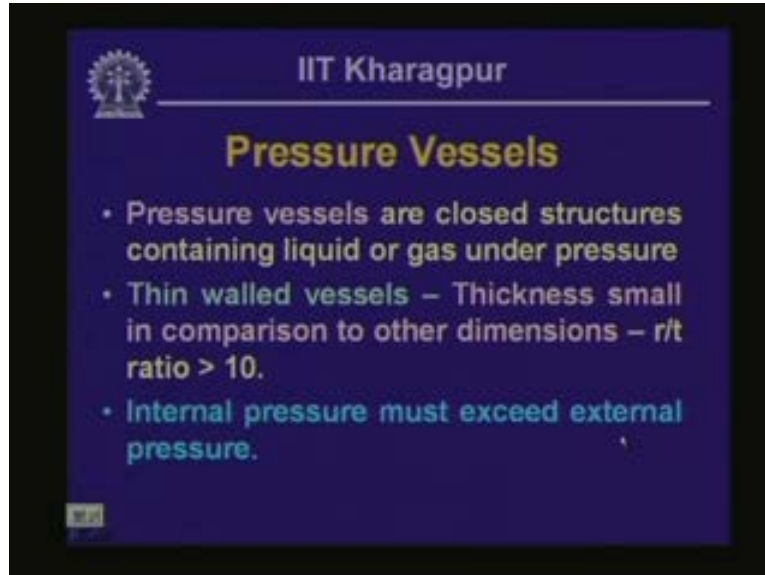

There is a diagram on the right side of the slide showing a cube of side length 'a' under hydrostatic pressure 'p'. The forces are shown as arrows pointing inward on all faces. The volume is labeled 'V', and the change in volume is labeled 'ΔV'. The equation  $e = \frac{\Delta V}{V}$  is written next to the diagram.

So if you look into this particular expression where  $e$  is equal to minus  $3(1 - 2\mu)$ , the minus indicates that it is under compression. Now if we have the value of  $\mu \geq 0.5$  then  $1 - 2\mu$  this particular quantity becomes negative. And once this becomes negative means the minus and minus becomes positive which indicates that  $\Delta_v$  is increasing that means the volume is increasing. That means if the value of  $\mu$  is greater than  $\frac{1}{2}$  then it states that there is an increase in the volume which is contradictory to the physical strain.

In the physical strain it has to see to that particular element is subjected to hydrostatic pressure from all directions. Thereby  $\sigma_x$ ,  $\sigma_y$  and  $\sigma_z$  are all minus  $p$  and now this is trying to compress the body. If we have the higher value of  $\mu \geq 0.5$  then it shows that it is expanding which is contradictory to the physical strain. So the maximum value of  $\mu$  that you can have is  $\frac{1}{2}$ . So as we had stated earlier also the maximum value of  $\mu$  is equal to  $0.5$ . These are the three questions that we had. And in fact these are the aspects which we had discussed in the previous lesson and if you go through the previous lesson you should be in a position to answer these questions.

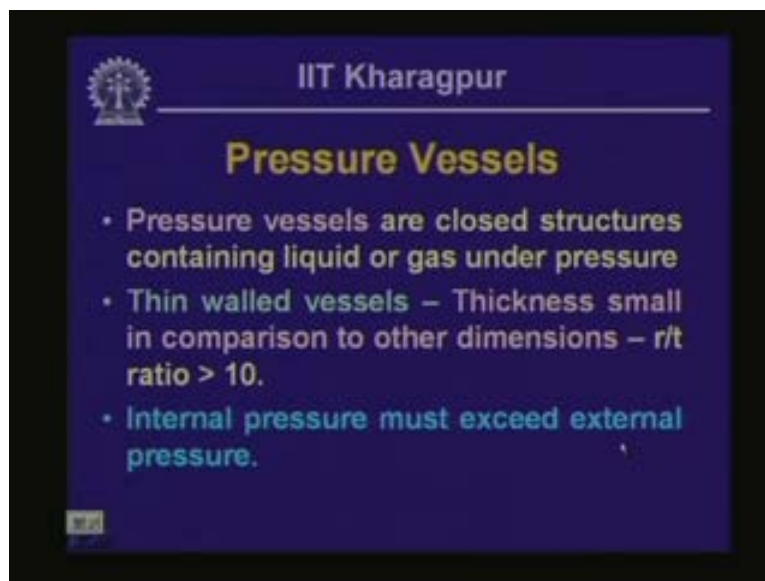

(Refer Slide Time: 21:13)

Pressure vessels are the containers in which the gas or liquid is put under pressurized condition and thereby it exerts pressure in the internal surface of the container and if that internal pressure is higher than the external pressure the body will be experiencing stresses and basically there will be tensile stress in the body. Our objective here is to evaluate those stresses in such pressurized containers. We use compressed air in most applications and another example of this type of pressure vessel is the water flowing through a thin-walled pipe.

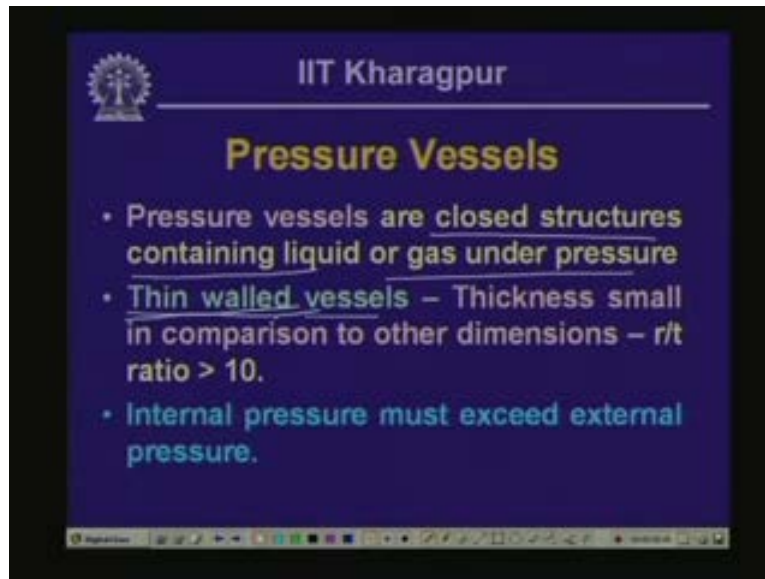

(Refer Slide Time: 22:29)

What is stated here is that the pressure vessels are closed structures containing liquid or gas under pressure. And we have qualified the terms pressure vessels with thin-walled because the

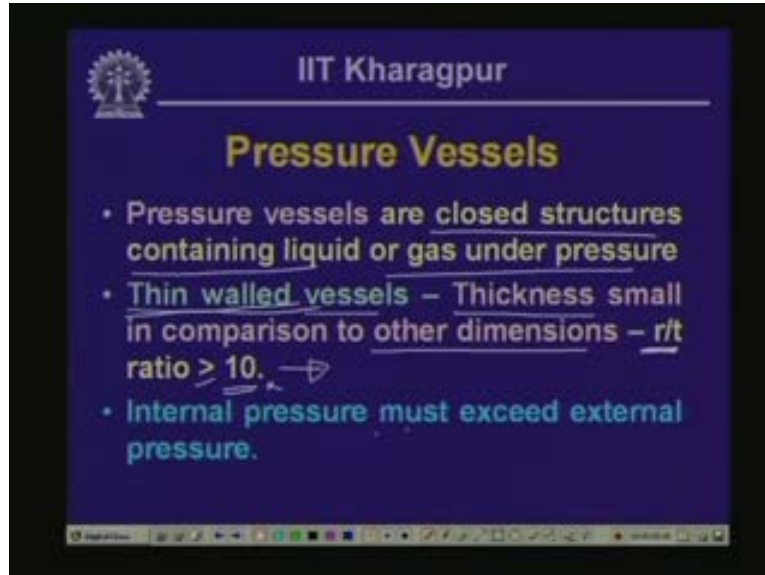

thickness of the wall or the thickness of the container wall is sufficiently small. It is so small that the variation of the stress across the thickness is insignificant and thereby we consider that there is a state of stress which is on the surface in two directions and the third direction stress is 0.

(Refer Slide Time: 23:26)

For those vessels for which the thickness is so small that in comparison to the other dimension that the ratio of  $r$  by  $t$  where  $r$  is the radius of the cylindrical tank and  $t$  is the thickness so if  $r$  by  $t$  ratio is  $\geq 10$  then we call those kinds of vessels as thin-walled vessel. The term ten or number 10 here actually is considered that it has been observed if  $r$  by  $t$  ratio exceeds value of 10 then the error in the stress level is the minimum and thus it is the limiting value considered for thin-walled vessels.

(Refer Slide Time: 23:50)

The slide features the IIT Kharagpur logo in the top left corner. The title "IIT Kharagpur" is centered at the top, followed by the main title "Pressure Vessels" in a larger font. Below the title, there are three bullet points: "Pressure vessels are closed structures containing liquid or gas under pressure", "Thin walled vessels – Thickness small in comparison to other dimensions –  $r/t$  ratio  $> 10$ .", and "Internal pressure must exceed external pressure." A small arrow points to the  $> 10$  part of the second bullet point. At the bottom, there is a standard presentation navigation bar.

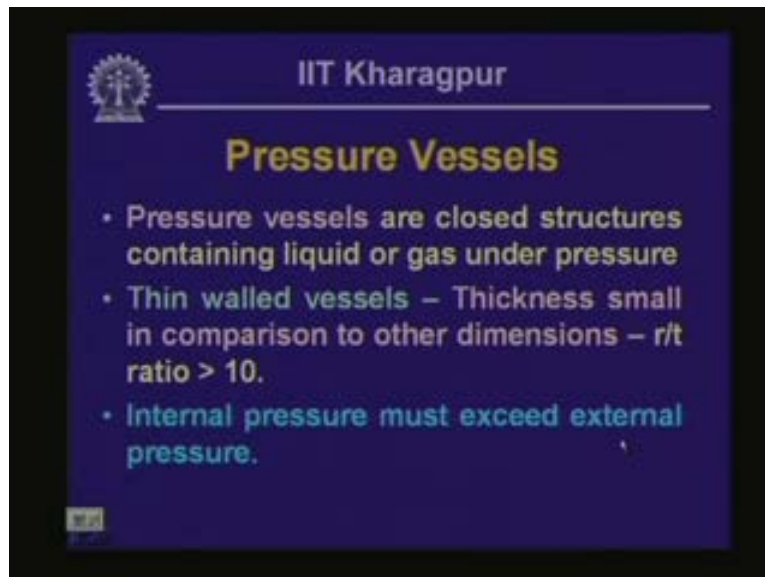

IIT Kharagpur

## Pressure Vessels

- Pressure vessels are closed structures containing liquid or gas under pressure
- Thin walled vessels – Thickness small in comparison to other dimensions –  $r/t$  ratio  $> 10$ .
- Internal pressure must exceed external pressure.

Actually the internal pressure must exceed the external pressure otherwise there will be other kinds of problems.

(Refer Slide Time: 23:51)

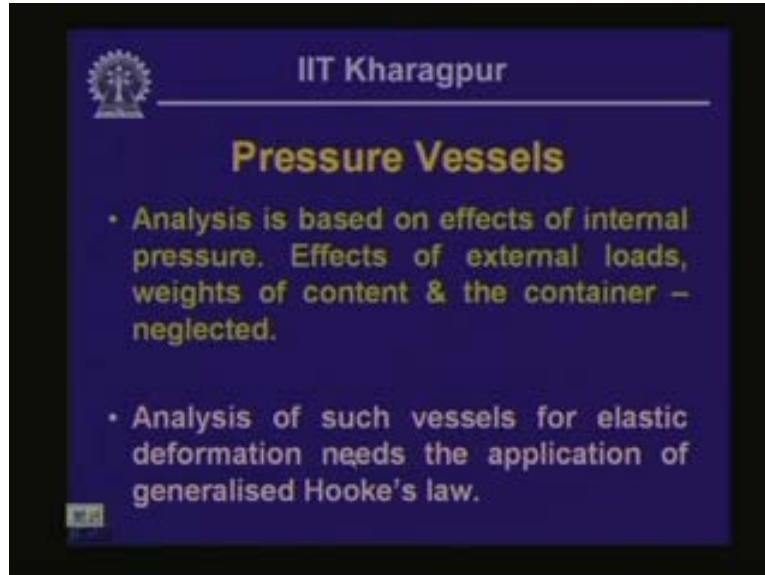

This slide is identical to the one above, showing the IIT Kharagpur logo, the title "IIT Kharagpur", the main title "Pressure Vessels", and the same three bullet points: "Pressure vessels are closed structures containing liquid or gas under pressure", "Thin walled vessels – Thickness small in comparison to other dimensions –  $r/t$  ratio  $> 10$ ", and "Internal pressure must exceed external pressure." The navigation bar at the bottom is also present.

IIT Kharagpur

## Pressure Vessels

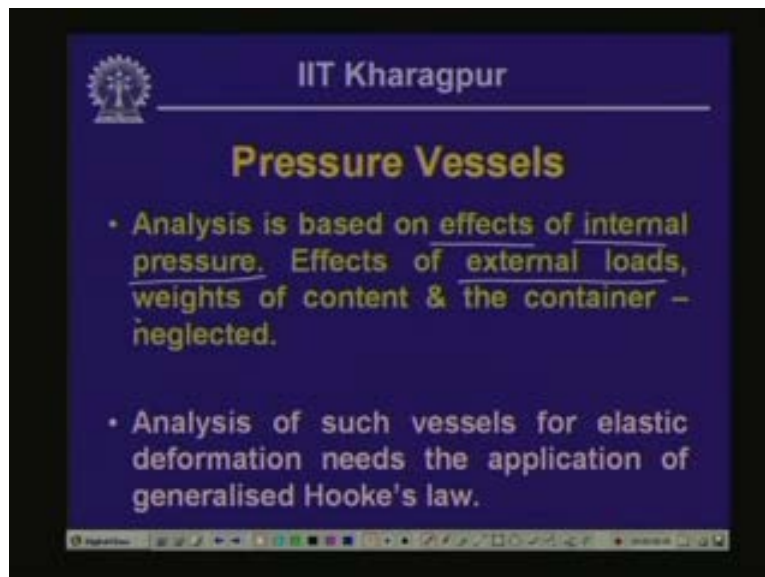

- Pressure vessels are closed structures containing liquid or gas under pressure
- Thin walled vessels – Thickness small in comparison to other dimensions –  $r/t$  ratio  $> 10$ .
- Internal pressure must exceed external pressure.

(Refer Slide Time: 24:10)

Basically in pressure vessels when we try to analyze we try to go for a simplified analysis and this analysis is based on the effect that the internal pressure exerts pressure or the forces on the body and thereby the body is subjected to stress. That is why we try to analyze how much stress the body undergoes when the container is subjected to pressure but we neglect other effects such as effects of the external loads, the weights of content and the weight of the container.

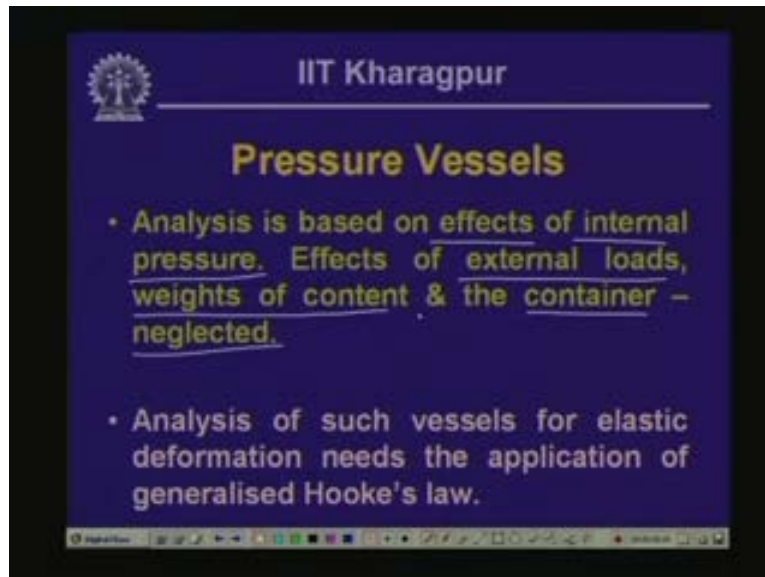

(Refer Slide Time: 24:35)

These aspects are neglected in this analysis. So when we try to analyze these kinds of pressure vessels we analyze the container for only stresses because of the pressure which is being exerted by the content from inside. We do not take the weight of the content, we neglect the weight of

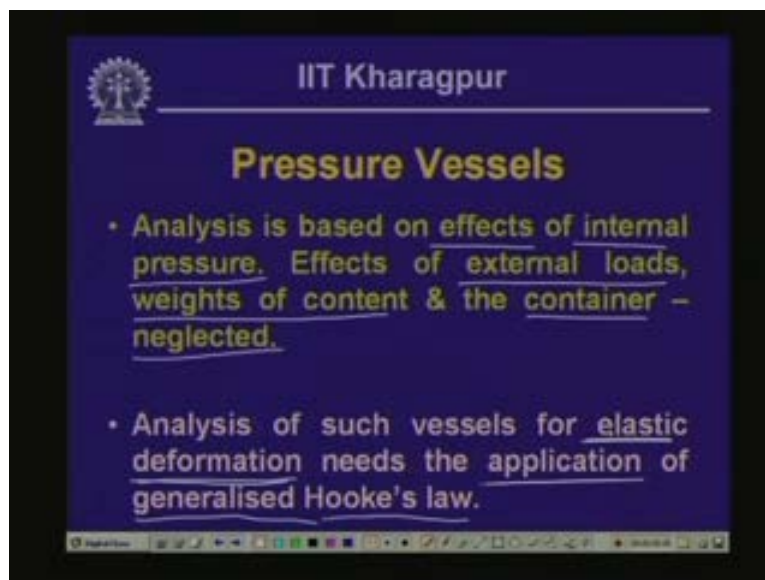

the container and we do not take the effect of any external loads that are acting on that particular container.

(Refer Slide Time: 25:12)

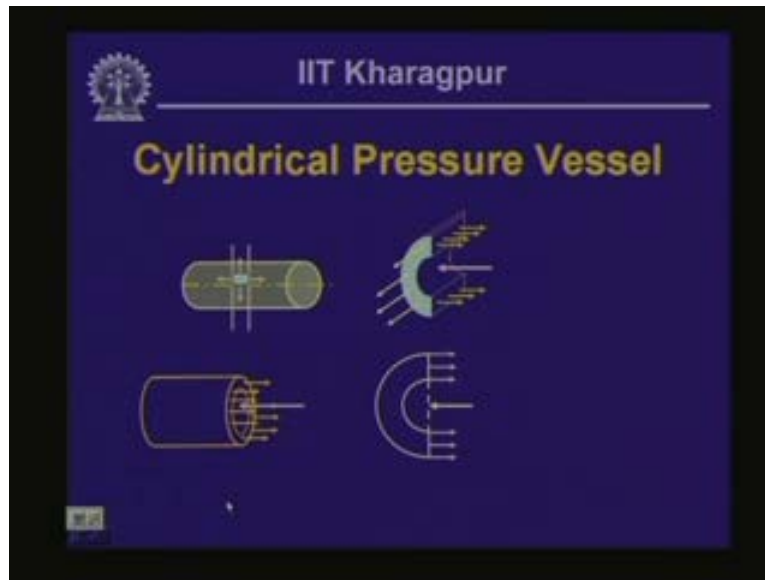

Also the analysis of such vessels for elastic deformation, when we try to compute the elastic deformation of such a container this needs the application of generalized Hooke's law. We have seen this where we compute the strain in terms of stresses in a generalized Hooke's law form where  $\epsilon_x$  is equal to  $\frac{\sigma_x}{E} - \mu \frac{\sigma_y}{E} - \mu \frac{\sigma_z}{E}$  and so on.

(Refer time slide: 25:37)

These are the generalized Hooke's law application and we take the applications of these for analyzing strains and thereby the deformation in the pressure vessels.

(Refer Slide Time: 25:53)

We can have different forms of pressure vessels but in this particular lesson we are concentrating on pressure vessels which are of cylindrical form. If we have a cylindrical pressure vessel which is exerted by pressure inside which is more than the external pressure then what will be the state of stress that will be acting on such containers?

(Refer Slide Time: 33:56)

Let us look into one such configuration that this is the cylinder, if we cut this cylinder and take a free body let us say this is a cut AA and BB these are the two planes by which we are cutting this cylinder and also we are cutting this cylinder along this center half then we get a configuration which is something like this. Here this is the thickness and this thickness is sufficiently small and this thickness is  $r$  by  $t$  where  $r$  is the radius of this cylindrical structure,  $r$  by  $t$  is equal to  $\geq 10$  and we call this kind of cylindrical form as thin-walled cylinder.

If we cut there are forces which will be acting and there will be internal pressure which will be exerted by the content. If we like to write down the equilibrium now this configuration can be written down in this form that this is the half cross section of the cylindrical container whereas this is the cylindrical part and this is the thickness of the cylinder and this is the center and this is the radius of the cylinder. This is internal radius and this is external radius so we can call this as  $r$  internal and this as  $r$  outer. And the stresses that will be acting, if we take an element on this cylindrical surface we have stresses acting in this form and stresses acting in the circumferential direction.

Let us call this as  $\sigma_1$  and this one acting in the longitudinal direction as  $\sigma_2$ . So, in the circumferential direction the stress acting is  $\sigma_1$  and the resulting force which is acting here is  $p$ , this also is  $p$  and the content is exerting pressure on this side. If we try to evaluate the value of stresses, here this  $p$  is equal to stress time area. The  $\sigma_1$  is the stress which is acting on the circumferential direction so  $\sigma_1$  into  $t$ , now if we take the distance between these two cuts as  $l$  which is this length of the segment and if we are computing stress for this particular length so  $\sigma_1$  into  $t$  into  $l$  where  $t$  into  $l$  is the area,  $\sigma_1$  is the stress so  $p$  is the force that is acting over here.

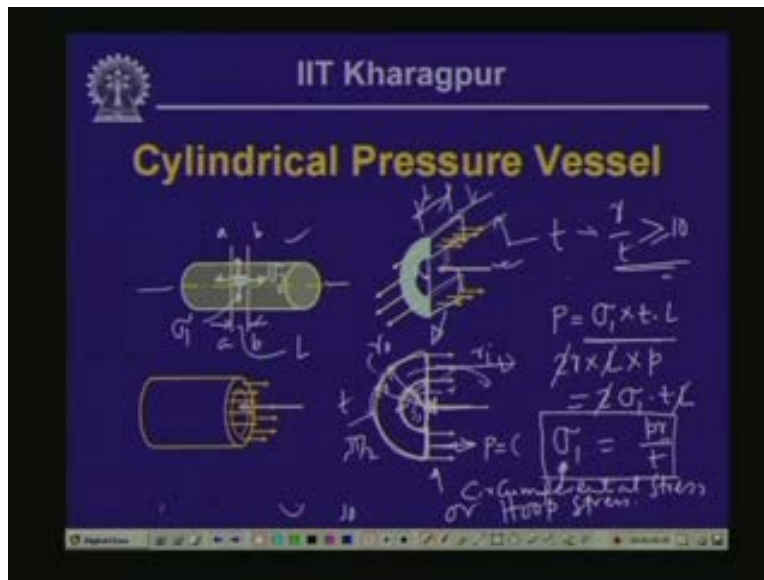

We can compute the values of  $\sigma_1$  in two ways. One is, supposing if we take this thin wall part and we say that this is subjected to the pressure from inside and here we have  $p$ , here we have  $p$  is equal to  $\sigma_1$  into  $t$  into  $l$ . Now if we consider a small element which is at an angle of  $\theta$  making an angle  $d\theta$  here so this is  $\theta$  and this is  $d\theta$ . Then the force which will be exerted here is equal to the internal pressure  $p$  star  $r$  star  $d\theta$  that is  $p(r(d\theta))$  and this is over the length  $l$ . If we take the component of this force in the horizontal direction which is  $\theta$  then this is this times star  $\cos \theta$  so the force which is acting is  $p r l d\theta \cos \theta$  and this is acting over the whole of this segment so this side we have  $p$  and this side also we have  $p$  so  $2p$  is equal to integral.

Now, if we integrate from 0 to 90 degrees for the two halves so  $2$  of  $0$   $2\pi$  by  $2$  into  $p r l \cos \theta d\theta$ . This gives us the value of  $\cos \theta d\theta$  is equal to  $\sin \theta$  is equal to  $1$  so this is  $2p r l$  and  $p$  is equal to  $\sigma_1 t l$ . So in place of we can substitute these as  $2\sigma_1$  into  $t$  into  $l$  is equal to  $2 p r l$ , if we equate this  $2$ , this  $2$  this  $2$  gets cancelled so we have  $\sigma_1$  is equal to  $p$  into  $r$  by  $t$  now this is called as  $\sigma_1$  which is called as a circumferential stress as it is acting along the circumference of the cylinder or sometimes we call this as Hoops stress. So, circumferential stress or the Hoop stress is equal to  $pr$  by  $2t$  Hoop stress. So this stress  $\sigma_1$  since it is acting around the circumferential direction we call that as a circumferential stress or Hoop stress, which is given as  $p$  is the internal pressure,  $r$  is the radius of the of the cylindrical vessel and  $t$  is the thickness of the wall.

We can compute this directly as well. We can compute the values of circumferential stress or Hoop stress from this particular figure. Now here again  $p$  is equal to (the stress into the thickness of the wall) into segment of length over which we are concentrating, and this is equal to  $p$ . And since the content is applying the pressure along with the liquid inside so this is the projected length over which this force is acting which is  $2r$  into  $l$ , this is  $2r$  into  $l$  into the internal pressure  $p$  is equal to  $2\sigma_1 l t$  into  $l$ . If we equate these two then from this we get the value of  $\sigma_1$  is equal to  $p r$  by  $t$ . So we can see that the value of the circumferential stress in a pressurized cylindrical vessel is equal to  $p r$  by  $t$  where  $\sigma_1$  is called the circumferential stress or hoop stress.

The point to be noted here is that I am using the value here as  $r$  though initially I stated two values of  $r$  where one is  $r$  internal and another one is  $r$  outer or the external. Since the thickness of the vessel is very small we consider that there is little variation between the internal radius and the external radius and we consider the radius as internal radius and compute stresses for all as we have assumed in the beginning that since the thickness is small the variation of stress across that thickness is negligibly small and hence we consider only one  $r$  which is the internal radius  $r$ . That is why here this is always written as  $r$ .

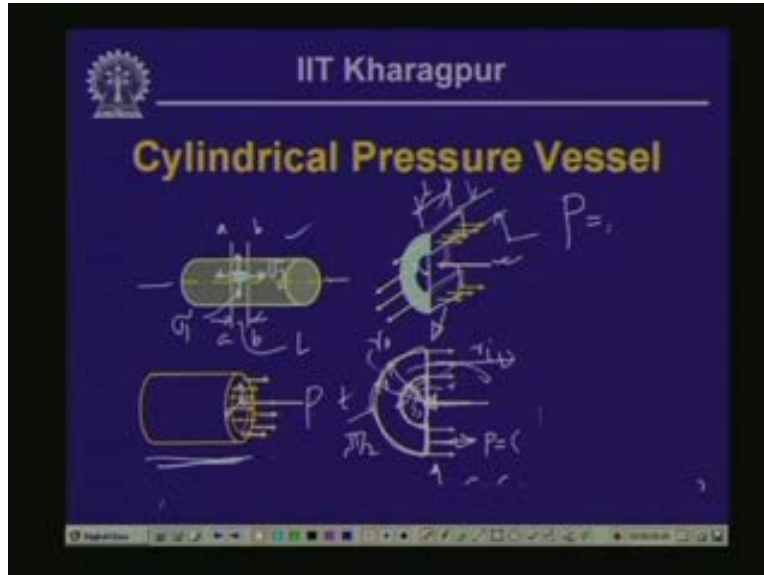

(Refer Slide Time: 35:30)

Now if we would like to compute the value of the other stress which is  $\sigma_2$  acting in the longitudinal direction then let us take the section here shown in this particular figure. Here you see that we have internal pressure which is acting on this particular surface and the thin wall which is subjected to the forces in this form resisting this internal one. Let us write in terms of internal and external radius over here, this is internal  $r$  and this is external radius. The pressure which is exerted by the content inside the pressure vessel is equal to the area which is  $\pi r^2$  multiplied by the intensity of the pressure.

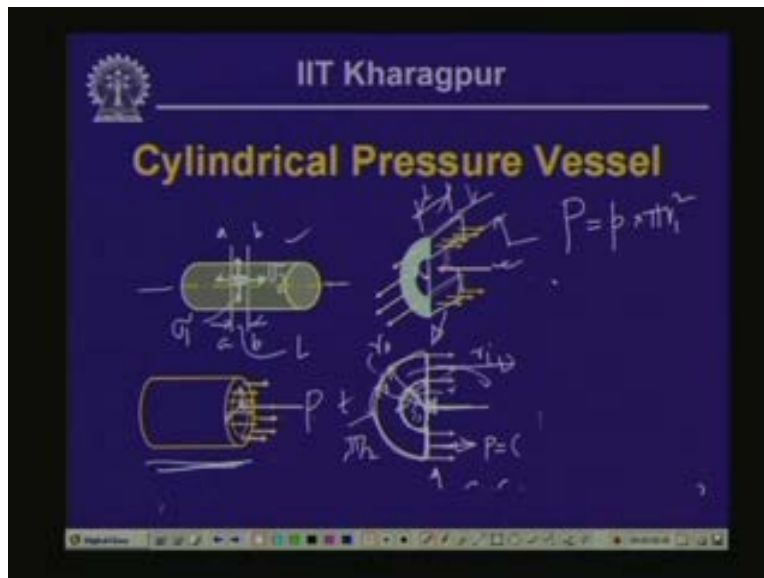

(Refer Slide Time: 35:50)

We can write this as pressure  $p$  into  $\pi r$  internal square. Now on the outer periphery on the thin wall which is between  $r$  internal and  $r$  external this is subjected to a force which is resisting this pressure from within.

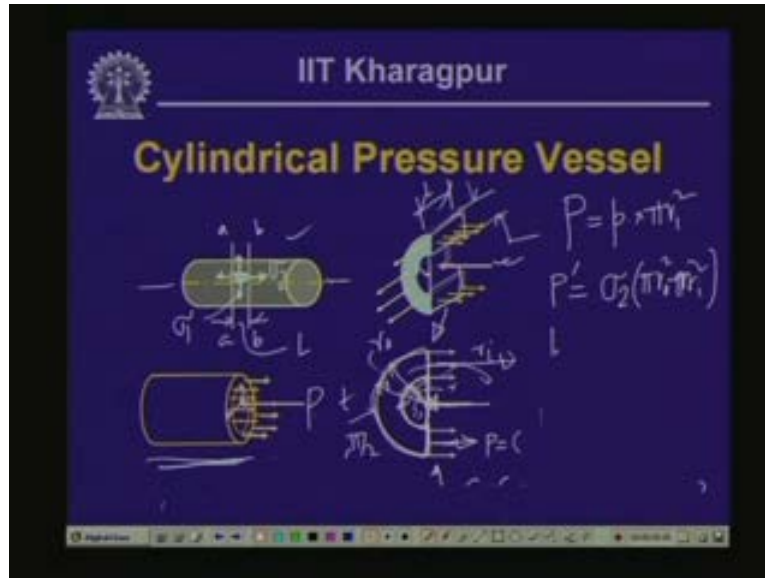

(Refer Slide Time: 36:28)

If we write down that as  $p$  prime is equal to  $\sigma_2$  the stress so now  $\sigma_2$  multiplied by the area will give us the force and the area is  $\pi r$  outer square minus  $r$   $\pi r$  internal square. So, from the whole of the cylindrical surface with external or outer radius  $r$  if we subtract the internal part with the  $r$  internal then the force given by the walls is equal to  $\pi r$  outer square minus  $\pi r$  internal

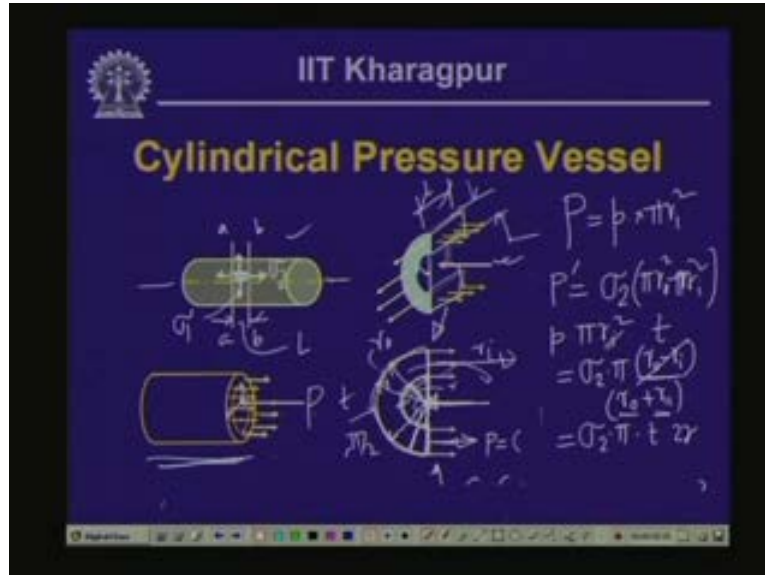

square multiplied by the stress. Thus the force that is going to resist this internal pressure is exerted by the content.

(Refer Slide Time: 37:43)

If we equate these two we can write  $p \pi r_i^2$  is equal to  $\sigma_2 \pi (r_o^2 - r_i^2)$ . Now  $r_o^2 - r_i^2$  we can write this as  $(r_o - r_i)(r_o + r_i)$ . It is  $r_o - r_i$  into  $r_o + r_i$  now  $r_o - r_i$  basically gives the thickness;  $r_o$  is this and  $r_i$  is this. Now the difference between these two is nothing but the thickness. So these we can replace as  $t$ , so this is equal to  $\sigma_2 \pi t (r_o + r_i)$ , here you see we have two quantities  $r_o$  and  $r_i$ . Since the thickness is very small and as I am telling you constantly that there is little variation between  $r_o$ ,  $r_i$  and  $r$  because the thickness is significantly small hence we consider  $r_o$  is equal to  $r_i$  is equal to  $r$ .

(Refer Slide Time: 39:02)

If you do that then this is basically  $2r$  and we have on the left hand side  $r$  square which is also  $r$  so we have now from this  $\pi$  gets cancelled  $r$  square and  $r$  gets cancelled so we have  $\sigma_2$  is equal to  $pr$  by  $2t$ . Now here we have obtain the expression for the longitudinal stress which is  $\sigma_2$  which is equal to  $pr$  by  $2t$ . Earlier we have seen that we have circumferential stress or the hoop stress  $\sigma_1$  as is equal to  $pr$  by  $t$  and now we have obtained the longitudinal stress which is  $\sigma_2$  which is in fact that half of this circumferential stress which  $pr$  by  $2t$ . So if we know the internal pressure, if we know the radius of the cylindrical vessel, if we know the thickness of the wall, we can compute the stresses; the circumferential stress and the longitudinal stress and both the stresses  $\sigma_1$  and  $\sigma_2$ . The circumferential stress or the Hoop stress and the longitudinal stress are basically tensile in nature.

### Cylindrical Pressure Vessel

The slide contains four diagrams illustrating the stress analysis of a cylindrical pressure vessel. The top-left diagram shows a cylinder with internal pressure  $p$  and a cross-section of length  $L$ . The top-right diagram shows a semi-circular cross-section of the cylinder wall with internal pressure  $p$  acting on the inner surface. The bottom-left diagram shows a full cylindrical cross-section with internal pressure  $p$  and wall thickness  $t$ . The bottom-right diagram shows a semi-circular cross-section of the cylinder wall with internal pressure  $p$  acting on the inner surface, and the resulting hoop stress  $\sigma_2$  acting on the wall.

$$P = p \times \pi r_i^2$$
$$P = \sigma_2 (\pi r_i t)$$
$$p \times \pi r_i^2 = \sigma_2 \pi r_i t$$
$$= \sigma_2 \pi r_i t$$
$$\sigma_2 = \frac{p r_i}{t}$$
$$\sigma_1 = \frac{p r_i}{t}$$

### Example Problem - 1

- An element of material in plane strain is subjected to strains  $\epsilon_x = 480 \times 10^{-6}$ ;  $\epsilon_y = 70 \times 10^{-6}$  and  $\gamma_{xy} = 420 \times 10^{-6}$ . Evaluate (a) the strains for an element oriented at an angle of  $75^\circ$  with x-axis in anticlockwise direction; (b) the principal strains and (c) maximum shear strain; using Mohr's circle.

Having looked into the concept of the stresses in the cylindrical vessels, let us look into some of the problems. Here are some problems with reference to the stress system or with reference to the Mohr circle of strain and the transformation equation. Let us also look into the examples of the pressure vessels.

(Refer Slide Time: 41:00)

IIT Kharagpur

### Example Problem - 1

- An element of material in plane strain is subjected to strains  $\epsilon_x = 480 \times 10^{-6}$ ;  $\epsilon_y = 70 \times 10^{-6}$  and  $\gamma_{xy} = 420 \times 10^{-6}$ . Evaluate (a) the strains for an element oriented at an angle of  $75^\circ$  with x-axis in anticlockwise direction; (b) the principal strains and (c) maximum shear strain; using Mohr's circle.

Here is the first example. What is stated here is that an element of material in a plane strain condition is subjected to  $\epsilon_x$  so much  $\epsilon_y$  is equal to  $70 \times 10^{-6}$   $\gamma_{xy}$  is equal to  $420 \times 10^{-6}$ . What you will have to do is to evaluate the strains for an element which is oriented at an angle of 75 degrees x -axis in anticlockwise direction and secondly the

principal strains and thirdly a maximum shear strain using Mohr circle. Now let's us look into how you compute the values of the principal strains such as the maximum shear strains and the strains which are at orientation which is oriented at an angle of 75 degrees with reference to the x axis.

(Refer Slide Time: 51:57)

Now, let me draw the Mohr circle corresponding to the state of stress which is given  $\epsilon_x$  is equal to 480 [10 to the power minus 6]  $\epsilon_y$  is equal to 70 [10 to the power minus 6]  $\gamma_{xy}$  is equal to 420 [10 to the power minus 6]. If we try to plot the Mohr's circle based on these values of strains then we have, let us say this is  $\epsilon$  axis and this is positive  $\gamma_{xy}$  by [2] or  $\gamma$  [2] axis. Now here we have the point which is the positive  $\epsilon_x$  and  $\gamma_{xy}$  by [2] and correspondingly we have  $\epsilon_y$  and  $\gamma_{xy}$  by [2]. If we join these two points together the line which crosses the  $\epsilon$  axis we get as the centre of Mohr's circle and this if we call as O, O prime or O A. If we take this as the radius then we can compute or we can draw the Mohr circle in this form.

Here this particular point indicates the value of maximum strain which is the principal strain equal to  $\epsilon_1$ . This strain is the minimum normal strain which we call as  $\epsilon_2$  and as you have seen the distance of the center from the origin is equal to  $(\epsilon_x + \epsilon_y)$  by [2] and the distance between these two points A A prime is  $(\epsilon_x - \epsilon_y)$  by [2].

If we designate them, let us say this is B prime and this as O prime and this as X and this as Y. So the distance O O prime is equal to  $(\epsilon_x + \epsilon_y)$  by [2] is equal to 480 plus 70 is equal to 550 by 2 is equal to 275 [10 to the power minus 6]  $\epsilon_x - \epsilon_y$  is equal to 410 [2] is equal to 205 [10 to the power minus 6]. Now this distance is  $\epsilon_x - \epsilon_y$  and from here to here is  $\epsilon_x - \epsilon_y$  by [2] and this distance is  $\gamma_{xy}$  by [2] is equal to 210 [10 to the power minus 6]. Thereby from this particular triangular configuration, this is 210 and this is 205 and this is the radius of the circle which is O A where O A is equal to R is equal to  $\sqrt{210^2 + 205^2}$  is equal to 293.5 [10 to the power minus 6]. Hence let me first compute the

principal strains  $\epsilon_1$  where  $\epsilon_1$  is equal to  $OO'$  or  $O' - O + r$  so  $O' - O + r$  and  $O'$  is equal to  $(\epsilon_x + \epsilon_y) / 2$  is equal to 275. So  $275 + 293.5 \times 10^{-6}$  is the strain and this gives us the value of  $568.5 \times 10^{-6}$ .

Now  $\epsilon_2$  which is the minimum principal strain or minimum normal strain is given by this distance and that is equal to  $r - O' - O$  and eventually that will become negative. Now  $O' - O$  is equal to 275 and minus  $293.5 \times 10^{-6}$  gives us a negative value and that is why the end of the circle has gone below the  $OO'$  point and this is equal to minus  $18.5 \times 10^{-6}$ . So it is  $\epsilon_2$  is equal to  $(275 - 293.5) \times 10^{-6}$  is equal to minus  $18.5 \times 10^{-6}$ . So this is the maximum principal strain and this is the minimum normal strain or the principal strain. The maximum shearing strain is the maximum value of the  $r$  is equal to  $\gamma / 2$  so  $r$  is equal to 293.5 so  $\gamma_{max}$  is equal to  $2r$  is equal to  $587 \times 10^{-6}$ . This is the maximum value of the shearing strain. These are the three quantities; maximum value of the principal strain  $\epsilon_1$ ,  $\epsilon_2$  and  $\gamma_{max}$  is this.

Now let us look into the angle. Since this is the point of the maximum principal strain the angle from the reference point is this which is  $2\theta_p$ , now this angle  $2\theta_p$ . So let us see the value of  $2\theta_p$ . Now  $\tan$  of  $2\theta_p$  is equal to 210 by 205 and thereby  $\theta_p$  or  $2\theta_p$  is equal to 45.7 degrees and  $\theta_p$  thereby comes as 22.85 degrees. This is the orientation along which the principal strain acts. Now we will have to compute the value of strain with reference to axis. We have the reference axis  $x$  and  $y$  so now we have to find out the state of strain at an orientation of the axis which is 75 degrees in an anticlockwise form with reference to  $x$ . We will have to find out the strain along  $x_1$  and  $y_1$ , now when we take 75 degrees in the reference plane in the Mohr plane then that becomes  $2\theta$  is equal to 150 degrees. From this particular reference point if we go to 150 degrees somewhere here so this is the point which will give us the state of stress which is oriented at an angle of  $75^\circ$  with reference to  $x$  axis.

From here to here this is 150 and  $2\theta_p$  we have obtained 45.7, this is 90 so this angle if we call this as  $\alpha$  then  $\alpha$  is equal to  $150 - 45.7 - 90$ . So this gives us an angle of 14.3 degrees so  $\alpha$  is equal to 14.3. Now from here if we draw a perpendicular then this distance is going to give us the value of the normal strain which we call as  $\epsilon$  is equal to 75 and if we take diametrically opposite this point we will get  $\epsilon_y$  and this value will give us the value of  $\gamma$  by  $2$ . If we know that this angle is 14.3 degrees and this is  $r$  then we can compute these distances and let us call this distance  $a$  and the vertical distance which is  $b$ . So  $\cos 14.3$  is equal to  $b$  or  $\sin 14.3$  is equal to  $a$ .

Now let us calculate the value of  $a$  and  $b$ . So  $a$  is equal to  $r(\sin 14.3)$  is equal to  $293.5 \times 10^{-6} [\sin 14.3 \text{ degrees}]$  is equal to  $72.5 \times 10^{-6}$  and the vertical distance  $b$  is equal to  $293.5 \times 10^{-6} [\cos 14.5 \text{ degrees}]$  is equal to  $284.4 \times 10^{-6}$ . Once we know  $a$  and  $b$  then the  $\epsilon_x$  or  $\epsilon_{x_1}$  is equal to  $OO'$  minus  $a$  the distance. Now distance  $OO'$  is equal to  $275 - 72.5$  which will give us the value of  $\epsilon_{x_1}$ . And  $\epsilon_{y_1}$  will be likewise  $275 + 72.5 \times 10^{-6}$  and  $\gamma_{x_1 y_1}$  by  $2$  rather  $x_1 y_1$  by  $2$  is equal to  $284.4$  the distance  $b$  and  $\gamma_{x_1 y_1}$  is equal to  $568.8 \times 10^{-6}$ . These are the values of strain  $\epsilon_{x_1}$ ,  $\epsilon_{y_1}$  and  $\gamma_{x_1 y_1}$  with

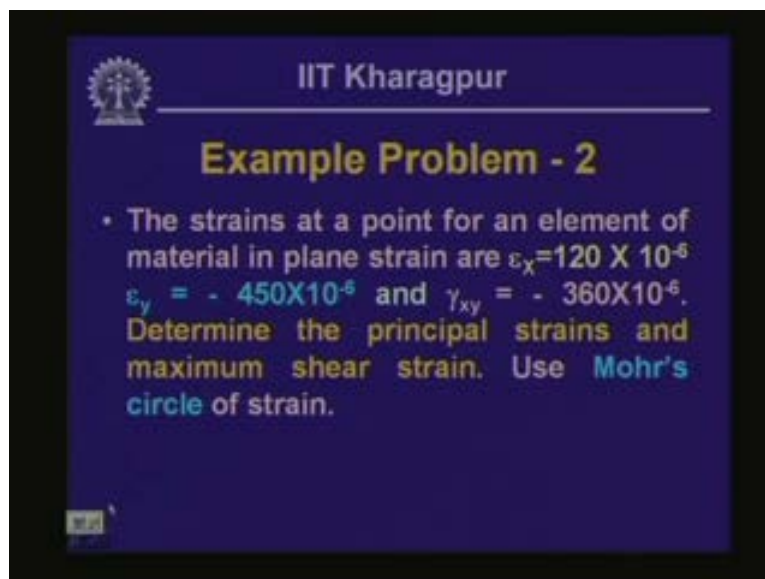

reference to the axis which is oriented at an angle of 75 degrees with reference to the reference x and y plane. So those are the values of the strains and the principal strains and the maximum shearing strength we have seen how to compute it.

(Refer Slide Time: 52:45)

Now this is the orientation, the final form of the reference plane. If this is the x direction and this is the y direction now when we have the orientation for the principal plane which is  $\theta_p$  is equal to 14.3 degrees. So this is the direction along which the principal strain acts, so this is  $\epsilon_1$  and in this direction we have  $\epsilon_2$ . Now  $\epsilon_2$  was negative and that is why it is compressed and this is elongated. Therefore this is the form of the principal strain.

(Refer Slide Time: 53:14)

Now let us look into the second problem which was stated as that the strain  $\epsilon_x$  is equal to  $120 \times 10^{-6}$ ,  $\epsilon_y$  is equal to  $-450 \times 10^{-6}$ ,  $\gamma_{xy}$  is also negative  $360 \times 10^{-6}$  you will have to find the principal strains and the maximum shear strain using Mohr's circle of strain.

(Refer Slide Time: 55:16)

Now if we plot the values of the Mohr's circle or if we plot the Mohr's circle based on the values given here, note that here we have the values of  $\epsilon_x$  is equal to  $120 \times 10^{-6}$ ,  $\epsilon_y$  is equal to  $-450 \times 10^{-6}$ ,  $\gamma_{xy}$  is equal to  $-360 \times 10^{-6}$ . Now if we plot this that  $\epsilon_x$  is equal to  $120$  and  $\gamma_{xy}$  is  $-180$ . Again this is positive  $\epsilon_x$  axis, this is equal to  $-\gamma_{xy}$  axis. So we have this as  $120$  and this as  $180$  so this is  $180$  because  $\gamma_{xy}$  is  $-360$  and this distance is equal to  $180$  which is  $\epsilon_x$  and likewise we have this point which is  $\epsilon_y$  is equal to  $-450$  is equal to  $180$ . With these if we join them and plot the circle then this is going to give us  $\epsilon_1$  and this is  $\epsilon_2$ . So we can compute the value of principal strain because  $r$  is equal to root of this square and this square and the principal strain is equal to the distance from centre to this plus  $r$  is equal to  $\epsilon_1$  and  $\epsilon_2$ . And  $\epsilon_1$  comes out to be  $172 \times 10^{-6}$  and  $\epsilon_2$  which is negative comes out to be  $-502 \times 10^{-6}$  and  $\gamma_{max}$  the shearing strain comes as  $674 \times 10^{-6}$ .

(Refer Slide Time: 55:54)

IIT Kharagpur

### Example Problem - 3

- A cylindrical steel pressure vessel is subjected to an internal pressure of 1.0 MPa. The radius of the cylinder is 1500 mm and thickness of wall is 10mm. (a) Determine the hoop and the longitudinal stresses in the cylindrical wall; (b) Calculate the change in diameter of the cylinder caused by the internal pressure.  $E=200$  GPa;  $\mu=0.3$

Here is the third problem which is related to the example as discussed today. Now here the cylindrical steel pressure vessel is subjected to an internal pressure of 1 MPa and the radius of the cylinder is 1500 mm and thickness of wall is 10 mm. We will have to determine the Hoop stress which is the circumferential stress and the longitudinal stresses in the cylindrical wall. Also, we will have to calculate the change in diameter of the cylinder which is caused by this internal pressure. Let us look into the values of the stresses as we compute.

As we have seen the circumferential stress  $\sigma_1$  is equal to  $pr/t$  and the longitudinal stress  $\sigma_2$  is equal to  $pr/2t$ . Now here  $p$  is given as 1 MPa,  $r$  is given as 1500 mm and  $t$  is equal to 10 mm. Hence  $\sigma_1$  the circumferential stress or the hoop stress is equal to  $1[1500 \text{ by } 10]$  is equal to 150 MPa and thereby  $\sigma_2$  the longitudinal stress the longitudinal stress is equal to  $pr/2t$  is equal to  $\sigma_1/2$  is equal to 75 MPa. The  $\sigma_2$  acts in the longitudinal direction of the vessel which is longitudinal stress and  $\sigma_1$  acts in the circumferential direction. Now if we like to find out the increase in the diameter then it means you must know how much strain it is undergoing in the circumferential direction. So we are interested to evaluate the strain in the circumferential direction which we call as  $\epsilon_1$ .

(Refer Slide Time: 58:49)

The image shows handwritten calculations and a stress element diagram. At the top, the formulas for hoop stress  $\sigma_1 = \frac{pr}{t}$  and longitudinal stress  $\sigma_2 = \frac{pr}{2t}$  are written. Below these, the given values are listed:  $p = 1.0 \text{ MPa}$ ,  $r = 1500 \text{ mm}$ , and  $t = 10 \text{ mm}$ . The hoop stress is then calculated as  $\sigma_1 = \text{hoop stress} = \frac{1.0 \times 1500}{10} = 150 \text{ MPa}$ . The longitudinal stress is calculated as  $\sigma_2 = \text{Longitudinal stress} = \frac{pr}{2t} = \frac{\sigma_1}{2} = 75 \text{ MPa}$ . To the left of these calculations is a square stress element with four arrows pointing outwards, labeled  $\sigma_1$  on the vertical sides and  $\sigma_2$  on the horizontal sides. Below the element, the strain  $\epsilon_1 =$  is indicated.

Now  $\epsilon_1$  is equal to  $\frac{\sigma_1}{E} - \mu \left[ \frac{\sigma_2}{E} \right]$ . Now if we substitute the values of  $\sigma_1$  and  $\sigma_2$  we will find that the value of strain which we are getting from here is equal to  $0.6375 \times 10^{-6}$  whole power cube. So this is the value of strain it is undergoing. Now we can write this strain in the circumferential direction as  $\frac{\Delta L}{L} = \epsilon_1$ . This is the extension by the original length which is equal to  $\Delta L$  by  $r$ . So the extension in the radius is equal to  $\epsilon_1 r$  is equal to  $0.6375 \text{ mm}$ . Hence the increase in the diameter  $2\Delta L$  is equal to  $2(0.6375) \text{ mm}$ . This  $r$  is equal to  $0.6375 \times 1500$  and this is  $0.6375 \times 1500$ . So this comes out as  $1.912 \text{ mm}$ .

**Question Set 3.1**

- What is Hoop stress and how is it related to longitudinal stress in cylindrical pressure vessels?
- What is the value of in plane shear stress?
- Are the stresses same in spherical vessels as observed in cylindrical vessels?
- Answers will be provided in the next lesson

The question set for you is:

What Hoop stress is and how is it related to longitudinal stress in cylindrical pressure vessels?

What is the value of in plane shear stress and are the stresses same in spherical vessels as well as we seen in cylindrical vessels?
