Discriminating Biological Protein Interfaces from Crystal Artifacts (Contd.)
(Refer Slide Time: 00:15)

CONCEPTS COVERED

- Protein crystal structure
- Biological interfaces

Inferring Biological Assembly from Crystal.

Pralay Mitra

KEYWORDS

- Protein crystal structure
- Biological interfaces

Pralay Mitra

Welcome back. So, we are continuing with discriminating biological protein interfaces from crystal artifacts. And also, I would like to add that in this lecture, I will be covering protein crystal structure, biological interfaces along with that one inferring biological assembly from crystal structure that I will be covering in today's class lecture. So, keywords are same.

(Refer Slide Time: 00:59)

Features at protein-protein interface

1. interface area (I_A),
2. normalized interface packing (NIP),
3. normalized surface complementarity (NSc),
4. normalized surface complementarity and interface packing paired metric (NSP),
5. accessible surface area variation ($asaV$),

$$asaV = (IA_{2,0} - IA_{1,8}) / IA_{1,4}$$
6. interface packing gradient (IP_g),
7. patch ratio (P_r),
8. normalized solvation energy capacity (NSE),

$$NSE = \frac{\sum \Delta \sigma(\text{Atom Type}) \times \Delta ASA}{\text{Interface area}}$$
9. hydrophobicity at interface (HPO_i),
10. hydrophobicity at the surface (HPO_s).

Symmetry in Protein Structure

State	Symmetry				
Monomer	C1				
Dimer	C2				
Trimer	C3	$C_{2,1,1}$			
Tetramer	C2, C2	D2	C_4		
Pentamer	C5	C_4, C_1	C_3, C_2	$D_{2,1,1}$	
Hexamer	C2, C2, C2	C3, C3	D3	C_4, C_2	
Heptamer	C_7				
Octamer	C2, C2, C2, C2	C4, C4	D2, D2	D4	
Nonamer	C3, C3, C3				
Decamer	C2, C2, C2, C2, C2	C5, C5			
Dodecamer	C2, C2, C2, C2, C2, C2	C3, C3, C3, C3	C4, C4, C4	D2, D2, D2	D3, D3

Pralay Mitra

So, these are the features using which we have designed one binary classifier. And I promise that this binary classification will be combined with the symmetry information in protein structure in order to generate the biologically functional forms. Now, just to give you one a recap of the symmetry in protein structure.

So, we mostly mentioned that when there is a symmetry the symmetry will be between the homomeric chains, not with the heteromer, but there is a possibility that there can be heteromer starting from dimer. So, in dimer there may be two different chains. If it is, then we will not find any symmetry there. If say, it is trimer then maybe two chains are same another is different, then, we are suggesting that the symmetry will be C2 between the known chains and C1 with the hetero chain.

Now, the C_1 actually for the monomer is basically no symmetry exists. Because as per the cyclic symmetry definition it is $360 \div 260$, which gives you one. Which means, if I give 360 rotation then you will get 1. So, it is easy to get or identify one symmetric axis about which if you give 360-degree rotation then you will get the same structure. So, that is trivial. So, that is why that C_1 I am not discussing much.

Now, the dimer if it is say homodimer then only I will get C_2 symmetry. If it is a trimer then I will get C_3 symmetry if it is homotrimer. If it is a heterotrimer then there are three possibilities So, heterotrimer two possibilities sorry. One is that all three chains are different then there is no symmetry at all, other is two chains are homo one is hetero. So, in that case actually I will have C_2 between the homo, and C_1 with the hetero that is written here C_2 and C_1 .

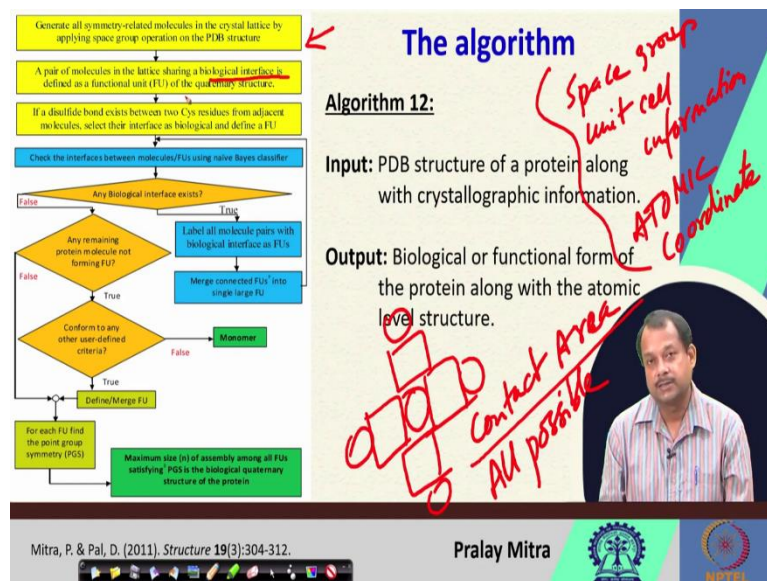

If it is tetramer and again so if it is hetero all chains are different, no question of any symmetry operation. But if say, it is consisting of all four same chains then there can be D_2 or C_4 . And if it is say consisting of two chains which are homomer, two another chains which are homomer but these two and these two are different like hemoglobin 2 alpha, 2 beta, so alpha and beta is not same.

So, between 2 alpha there will be C_2 , between 2 beta there will be C_2 so, that is C_2, C_2 . Therefore, pentamer it is C_5 or based upon, if it is a heteromer then based upon how many homo structures are there, so, it can be C_4 and C_1 , it can be C_3, C_2 . So, possibilities are C_4, C_1, C_3, C_2 . It can be D_2, C_1 so these many possibilities are there.

So, if it is a hexamer then all $C_2, C_2, C_2, C_3, C_3, D_3$ or can be C_4, C_2 , so that can be possible. If it is heptamer ideally, C_7 can be one symmetry, rarely, we will find any C_7 . So, the reason I mentioned also during their symmetry discussion, so even number of symmetry, I mean, the even number of biological assembly dimer, hexamer, heptamer, dimer, tetramer, hexamer, octamer, decamer, those are occurring in nature more frequently compared to the odd number of assembly.

But in this odd number of assembly trimer occurs smore, so for trimer we will not consider that one and monomer of course, is not an assembly, so we will exclude. But from pentamer, heptamer, nonamer, so their occurrences are very less.

(Refer Slide Time: 05:16)

Now, let us go to that algorithm for which we waited long. So, here is the total flow diagram of the algorithm, not stepwise but as a flow diagram. Input is, PDB structure of a protein along with crystallographic information output biological or functional form of the protein along with the atomic level structure.

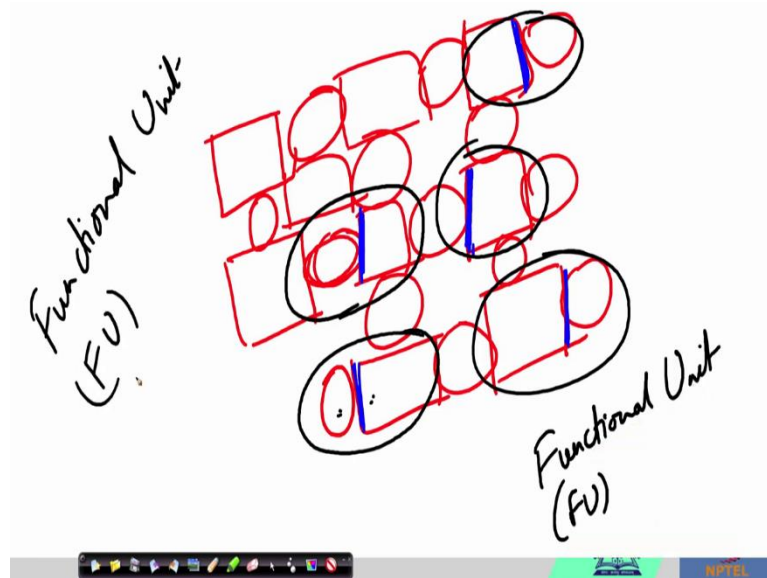

Now, let me go through the algorithm step by step. So, first you need to generate all symmetry-related molecules in the crystal lattice by applying space group operation on that PDB structure. So, it is possible. So, you need to have space group and unit cell information. Along with, of course, the atomic coordinate. If you have all this then definitely you can generate symmetry-related in the crystal lattice by applying the space group operation.

So, in one of the lectures I demonstrated you that using pimol, I generated that one, but it can be generated using program also. Once you will generate then a pair of molecules in the lattice sharing a biological interface is defined as a functional unit of the quaternary structure. So, there is a gap between these two steps. So, read between the lines. So, what do you need to do once you generate the lattice basically, so you need to identify the contact area, which contact area, all possible.

So, all possible contact area you need to identify. Then, on all possible contact area you need to run that binary classifier that we discussed along. 10 features Naive Bayes classifiers, but I also suggested you can increase the number of features, you can redefine the features, recalculate the features and instead of base you can apply some random for rest or other classification technic also, it is fine. So, but the requirement is that you have to go for one binary classification. Once you will have that binary classification then what will happen

among all those contact area few will be identified as the biological interfaces. Now, a pair of molecules in the lattice sharing a biological interface is defined as a functional unit of the quaternary structure.

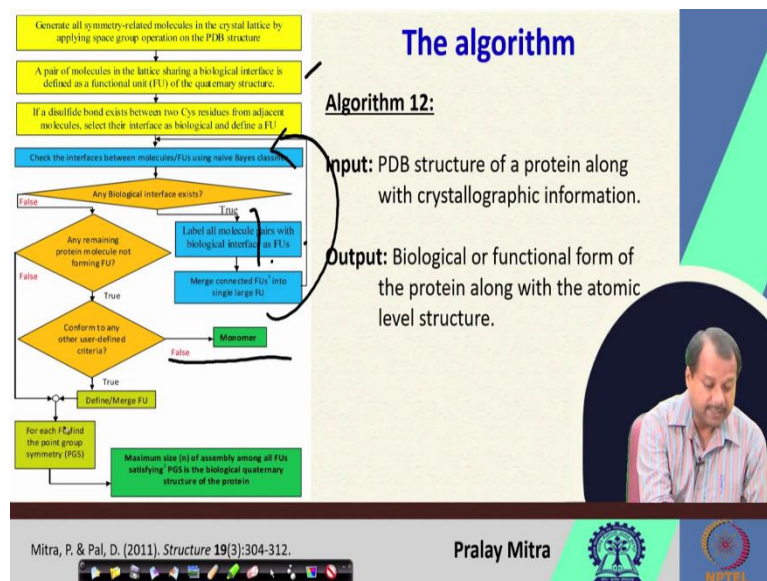

(Refer Slide Time: 08:02)

So, what I am suggesting now or the algorithm says that, if say, let me take a separate structure on this one. So, that one was better actually. In 2D I am drawing, in 3D I believe you will be able to understand. So, the crystal structure is there. Now, let us assume that blue color is indicating the crystal interface, the interface which are biologically relevant.

Then, as per the definition let me pick pink or black. This is one functional unit, this is one functional unit this is one, this is one, and this is one. What I am doing here now, first, I am generating the crystal lattice. After generating the crystal lattices all possible contact area has been identified. I run the binary classifier to check whether they are biologically relevant or not. If yes, then all those interfaces and the corresponding subunits or the chains, which are actually contributing to that interface is explaining me that it is going to be one functional unit. In short FU, it is going to be the functional unit. In short it is FU. So, that FU I am considering.

(Refer Slide Time: 10:37)

Now, this is my FU here. Along with this, if a disulfide bond exists between two cysteine residues from adjacent molecules select their interface as biological and define as FU. So, what it is suggesting that okay you identify the FU using binary classifier it is fine. But if you find that there exists some disulfide bond because of its interaction potential.

And since disulfide bonds are one of the most strong, strongest bond, which determines a non-covalent bond, which determines mostly the fold or the structure then you declare that also even if your binary classifier fails to identify that interface, as a correct biological, but you please define that one also as biological one and consider that as a FU. That way you will have in number of FU.

Now, check the interfaces between molecules are FU Naive Bayes classifier that we did. Then any biological interface exists, yes. If it is true, label all molecule payers with biological interfaces as FUs. So, you combine and grow your FU. Look, these FUs are going to be your biological unit.

So, you started with the binary classification and each interfaces you are identifying as biological relevant. If they are biologically relevant then you are considering these two as a correct one. So, these are dimer, if these two are dimers then what I am going to do is that this is my FU.

After concerning this FU, with this, then it will be one single unit. With this FU anybody else is interacting. Ad whether that interface is biological if, yes, then you consider that one also part of this FU. That way you are growing the FUs. From 1 then 2, 3, 4, 5, 6, that way you are

growing, and that rowing is done in this true part. So, label the biological FU merge connected FUs into single large FU, go back. And keep on iterating as long as you can combine that FUs. Any biological interface exists, when you will not find anyone then any remaining protein molecule not for me FU so then, true, conform to any other user defined criteria.

If you say that like the disulfide bond, I have another criteria to identify that whether it will be forming a FU or not then basically you can add that one, otherwise, you declare that as a monomer. And if it is then define the margin FU for each FU find the point group symmetry. So, before this finding the point group symmetry let me show you here.

(Refer Slide Time: 13:33)

The image is a composite of two parts. The top part shows a hand-drawn diagram illustrating various protein oligomers: Tetramer, Dimer, Tetramer → Dimer, Heterotrimer (labeled Cys4), Heteropentamer (labeled Cys4), and Heterononamer. The bottom part is a screenshot of a presentation slide titled "The algorithm" with a flowchart and handwritten annotations. The flowchart steps are:

- Generate all symmetry-related molecules in the crystal lattice by applying space group operation on the PDB structure.
- A pair of molecules in the lattice sharing a biological interface is defined as a functional unit (FU) of the quaternary structure.
- If a disulfide bond exists between two Cys residues from adjacent molecules, set a flag for interface as biological and define a FU.
- Check the interface between molecules/FUs using naive Bayes classifier.
- Decision: Any biological interface exists?
 - If True: Label all molecule pairs with biological interface as FU.
 - If False: Any remaining protein interface for biological interface?
 - If True: Connect FUs into single large FU.
 - If False: Conform to any other user-defined criteria?
 - If True: Define FU.
 - If False: For each FU find the point group symmetry (PGS).
- Final step: Maximum size (n) of assembly among all FUs satisfying PGS in the biological quaternary structure of the protein.

Handwritten annotations on the slide include "Tetramer", "Dimer", "Tetramer → Dimer", "Heterotrimer", "Heteropentamer", and "Heterononamer" written in blue ink. The slide also includes the text "Algorithm 12:", "Input: PDB structure of a protein along with crystallographic information.", and "Output: Biological or functional form of the protein along with the atomic level structure." The slide footer mentions "Mitra, P. & Pal, D. (2011), Structure 19(3):304-312." and "Pralay Mitra".

So, I combined, say, this is one. And after the communism I have grown. And because of my growth so, I got this one, and this one, say, I got this one. And I can also get, so I am going and I get this one, I can also get this one, I can also get. So, it may possible that from one crystal lattice, I may have one large FU, and small, small FUs, it may possible. If, yes, then you instead of picking the largest one you report everything.

Because it is known that a protein in different environmental condition may behave differently. So, in some situation, it can have a tetramer, in some situations and the same protein may act as a dimer, in some situation or in solution it can exist as a dimer, trimer both. So, where he will see, that trimer is converting to dimer and dimer is converting to tetramer. So, in equilibrium, they exist.

So, my suggestion will be during this prediction process if you come up with a number of FUs whose number of subunits are, it is greater than 1. So, it is 1 that is monomer, so you can erase that one. If that is the only FU then it is fine then you report as a monomer, otherwise, if you have different FUs functional units of which one is with one chain size then you can exclude that one, but do not exclude rest. So, you keep all the FUs. This is one, this is one, this is one, you keep all of them.

After keeping all of them, then what it suggests the theory, for each if you find the point group symmetry. So, for each FU, so this, this, this. What is the point of symmetry in this case? In this case, it is going to be a heterotrimer so there is C₂ and C₁ so heterotrimer. In this case what I am getting, it is heteropentamer, C₄, C₁. In this case, it is 1, 2, 3, 4, 5, 6, 7, 8, 9, nonamer.

Now, this heterononamer, heterotrimer, heteropentamer, among these this heterononamer is unlikely. Because as I mentioned if you go odd number of assembly state then a nonamer etc then it is not much likely. However, if you find that there exist two quaternary states which can make some equilibrium like say tetramer and dimer kind of thing. Say, in that case say trimer and hexamer or say pentamer and decamer then that may perhaps possible.

But in this case say, heterononamer, heterotrimer, heteropentamer, and as such there is no symmetry related information because here what I can see, C₄, C₄, C₁, for heterononamer. For heterotrimer, C₂, C₁, for heteropentamer, C₄, C₁. So, C₂, C₄, C₄, so this with this one and this one there is some similarity, and with this one and this one there is no such similarity.

So, if heterotrimer is possible then, perhaps, hetero pentamer is not possible okay. But if you look at the structure, so C2 and C1. Here C2 and C1 here C2 and C1, here C2 and C1 so that way perhaps hetero nonamer maybe a solution. So, this kind of fine tuning you have to do after you identify the symmetry in formation.

So, maximum size of assembly among all FU satisfying PGS point group symmetry is the biological quaternary structure of the protein. So, that is the final output. But there are some scope to improve, say, the way you are identifying the symmetry of information like whether it is cyclic symmetry, dihedral symmetry, so there is a huge scope to improve that one. And as of now, the approach is like growing.

So, where you are starting with one single subunit and then you are appending by using the binary classifier whether it will be connected that way you are growing. Another approach may be shrinking. So, you consider the large size of lattice say I start with say decamer or do decamer that is the functional unit.

Then, you go on excluding that okay this is not going to be as per either symmetry or by using some machine learning or say deep learning information, you exclude some say internal classification information, you exclude some of them, and then, you reduce the steps.

(Refer Slide Time: 19:53)

	Monomer	Dimer	Trimer	Tetramer	Hexamer	Octamer	Nonamer	Dodecamer
Set1	96	76						
Set2	55	88	24	38	13			
Set3*	-	66	24	11	5	2	1	3

*only heteromers

So, for the validation, you can use three different sets, so which are readily available. So, among this third set is consisting of only heteromers. So, these are my used validation data set, but you can come up with your own data set also. For the set 1 so, 96 monomers and 76 dimers are there. As you understand that for this only one binary classifier is enough. You

need not have to go for this computational framework for symmetry-related information etc. Then for set 2, 55 monomer, 88 dimer, 24 trimer, 38 tetramer and 13 hexamer. Look, so as I keep on increasing then this pentamer is missing, and then, nonamer is there, but heptamer is missing. So, which means odd number of mers are usually not very frequent.

In the set 3, there is no monomer but 66 dimer, 24 trimer, 11 tetramer and 5 hexamer, 2 octamer, 1 nonamer and 3 dodecamer so 12 size, dodecamer means 12 size, so 12 sizes are also there. So, that is the validation data sets you can use.

(Refer Slide Time: 21:12)

The slide features a title 'Is IA alone enough for prediction?' in blue text at the top. Below the title are three bullet points: 'The ratio of correct and maximum contact area vary between 36% to 100% with a mode value around 85%', 'There are 66 dimers and 47 multimers.', and 'The success rate of the servers (PQS, PITA) which use IA as a main feature is limited.' To the right of the text is a circular video inset showing a man in a striped shirt. At the bottom of the slide, there is a navigation bar with the name 'Pralay Mitra' and logos for IIT Delhi and NPTEL.

Then, the question is, is IA which means interface area alone enough for prediction? The ratio of correct and maximum contact area vary between 36 percent to 100 percent with a mode value around 85 percent. There are 66 dimer and 47 multimers. The success rate of the servers like PQS, PITA, which use IA as a main feature is limited, and that is perhaps, one of the reason why the support for these PQS and PITA has stopped.

Protein Data Bank in Europe
Bringing Structure to Biology

PDBePISA (Proteins, Interfaces, Structures and Assemblies)

PDBePISA is an interactive tool for the exploration of macromolecular interfaces. With PDBePISA, you can:

- Retrieve pre-calculated results for the whole PDB archive.
- Calculate results interactively for structures uploaded as PDB or mmCIF files.

These calculated results include:

- atomistic and chemical properties of macromolecular surfaces and interfaces
- probable quaternary structures (assemblies), their structural and chemical properties and probable association pattern
- search the PDB archive for particular interfaces formed by structure keywords
- search the PISA database of pre-calculated results using a wide range of values, such as:
 - multimers data,
 - sequence overlap,
 - same group,
 - macromolecular surface area,
 - free energy of dissociation,
 - presence/absence of each bridge and disulfide bonds,
 - monomer type,
 - ligands,
 - residues
- assess the significance (biological risk) of macromolecular interfaces
- download and visualize structures, interfaces and assemblies using [RasMol](#) (Linux/Unix platform), [RasMol](#) (MS Windows platform) and [Jmol](#) (platform independent server-side java viewer)

We welcome your feedback! Please send any questions, comments, suggestions and bug reports using the **FEEDBACK** button from the top of the page.
PISA queries may be searched from any web site by following [these instructions](#).
PISA data may also be downloaded using [small data links](#) ([instructions](#)) here.

PIGS is a community effort that facilitates the investigation and creation of quaternary structures. Given a PIGS identifier or a protein sequence, it displays information about the quaternary structure of homologue proteins on a single webpage. This information allows a quick comparison of the quaternary structure(s) of the members of a protein family. So far, the software has allowed for manual inspection of ~1000 structures of PIGS Biological Data, of which about 15% were found to be likely errors in a galaxy.

NEW Several features have been added in this new release!

- Like in 3D Complex, you can roll over a graph node to search homologues (i) by complex, (ii) by polypeptide chain, or (iii) by domain.
- You can now view or download a structure by clicking on the "3D" link ("3" for Rasmol).
- We started a project that consists of the curators of [UniProt](#) (see [UniProt](#)).
- A **Quality** index reflects the probability for a protein to be "quality", enables one to curate likely errors first.
- You can have a look at the "check of the data", create it, and enter the new [UniProt](#).

Please, **update** and **participate** to the quaternary state annotation of PIGS structures!

If you would like to refer to PIGS, please cite:
Ley E D. PIGS: protein-quaternary structure investigation. Structure 2007 Nov;15(11):1364-7. [PubMed](#)

Pick of the day - is this protein correct?

This protein is likely to have a wrong quaternary structure because: (i) it does not form a dimeric symmetry ([see table for details on symmetry](#)), and (ii) it shows 32% sequence identity with a symmetric dimer. You can contribute to PIGS by looking at the page and annotating the quaternary state.

The screenshot shows the PDBePISA website home page. At the top, it says "Protein Data Bank in Europe" and "Bringing Structure to Biology". The main heading is "PDBePISA (Proteins, Interfaces, Structures and Assemblies)". Below this, there are sections for "PISA links" and "Other links". The "PISA links" section includes: Disclaimer, Tutorials, Installation, Project, Submitting to PISA, Data, Download, Version log, Publications, PISA status, and PISA support. The "Other links" section includes: PDB-EM, CSD, CSDb, PDBsum, Email, Structure, Protein Data Bank, and PISA. The main content area describes PDBePISA as an interactive tool for the exploration of macromolecular interfaces. It lists features such as: Retrieve pre-calculated results for the whole PDB archive, Calculate results interactively for structures uploaded as PDB or mmCIF files, and search the PDB archive for particular interfaces formed by structure homologs. At the bottom, there are navigation tabs for Services, Research, Training, Industry, and About us.

The screenshot shows the "PISA Query" interface. It has tabs for "Submission Form", "Structure Analysis", and "Database Searches". The "Structure Analysis" tab is active, showing a search for "PDB entry: 5YU2". The analysis results show: "Analysis: 1 amino acid chain and 7 ligands in ASU", "Most probable assembly: 1 monomer", "Process ligands: SO4, GOL", and "Processing mode: auto". Below the results, there are buttons for "Statistics", "Monomers", and "Assemblies". The footer contains contact information for EMBL-EBI and copyright information.

The screenshot shows the "view structure" interface. A modal window is open with the following options: "Background" (set to "Blue"), "Zoom" (set to "100%"), "Screen" (set to "100%"), and "Light". There is a "Close" button at the bottom of the modal. The background shows a blurred view of the PDBePISA website.

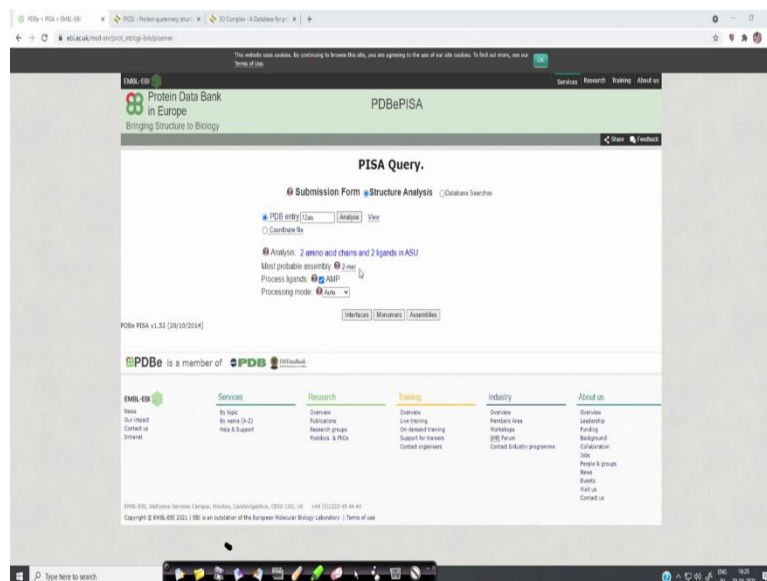

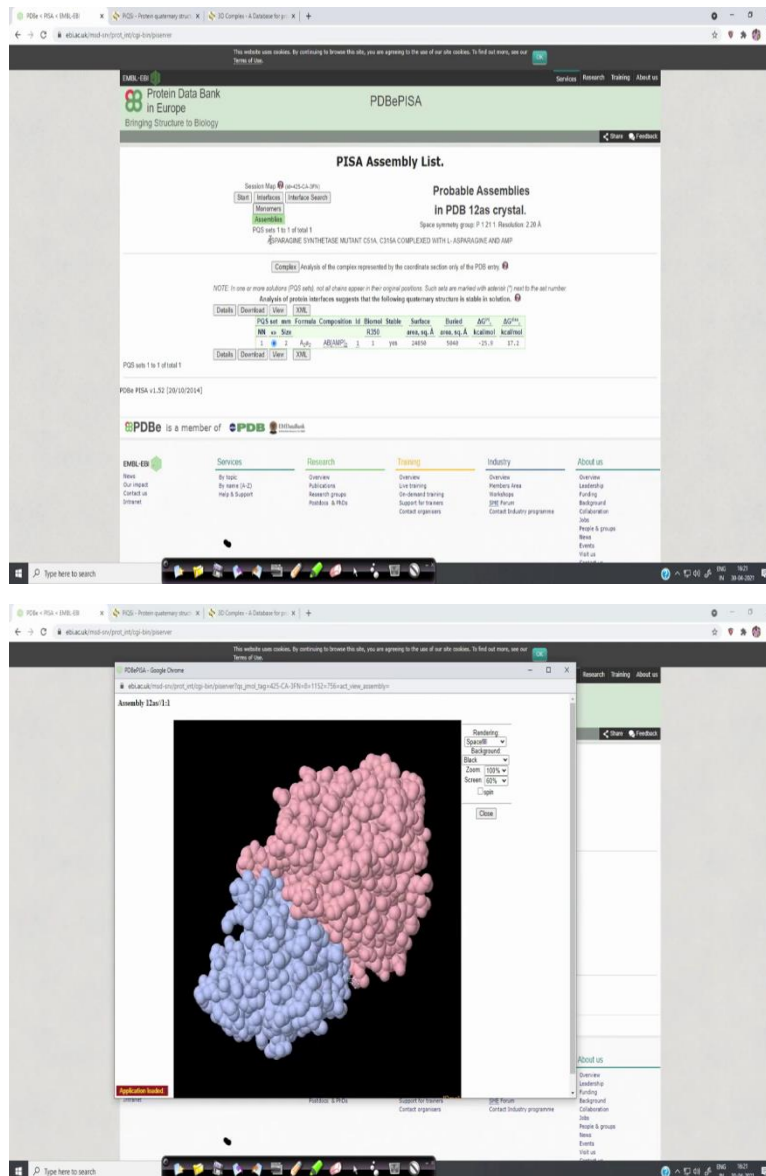

Now, interesting is this PISA. Let me go to this in detail. Launch PDBePISA. So, when you will be here then so you can give one PDB entry. So, one entry could be say 1 2 as. So, automatically when it will give then it will analyze that one. So, after analysis two amino acid chains it is mentioning to me acid chains and two ligands in ASU, asymmetric unit ASU asymmetric unit. Most probable assembly is 2-mar, 2-mar means dimer it suggest.

So, there are some ligands AMP. If you want you can process otherwise you need not have to process. Now, you can analyze usually it analyzed automatically but if you want to analyze that one then you can go for the view. So, this is the structure. So, this is the spacefill structure rendering you can go to the cartoon So, if you go to the cartoon so hetero items are in the spacefill. It is here, you can see that one.

Now, you see that there is a C2. The first thing is that you have to identify what will be my axis of rotation. For C2, mostly it is easy to identify say this can be one axis at this point passing perpendicular to this plane. If I look from here then also here, I can have one axis passing perpendicular to this page like that way. Then, this is one structure.

(Refer Slide Time: 26:01)

Now, if you wish to look at the interface so, then you have to go to assemblies. So, here in the assembly what you are getting, so, the asparagine synthesis mutant C51a, C315a complexed with L asparagine and AMP that is given. What is the space symmetry group P121 1 that is given, it is a crystal structure resolution is 2.20 angstrom.

Complex analyze of the complex represented by the coordinate section only of the PDB entry. Now, analysis or PDB, analysis of protein interfaces suggested that suggests that the following quaternary structure is stable in solution. So, download details, view, XML all are here. So, if you wish to view it is the same link that we opened. So, in JSmol it will be open so, this is the for your view.

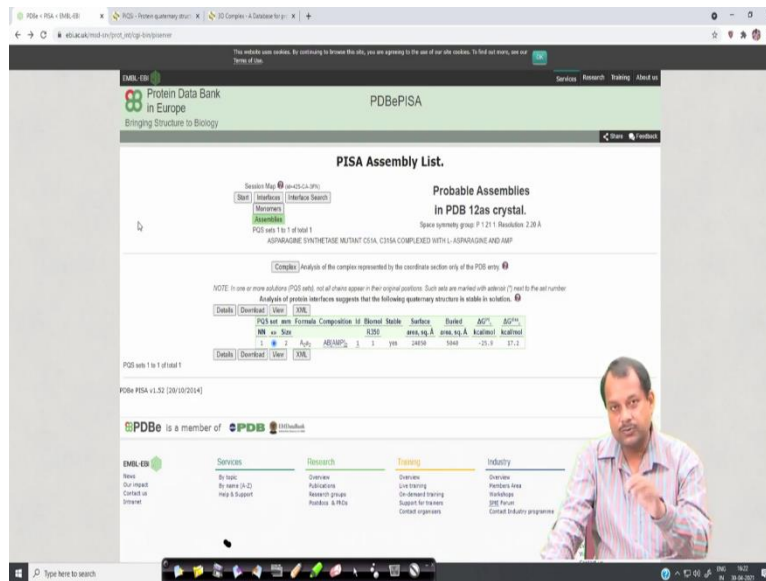

(Refer Slide Time: 26:59)

The screenshot shows the PDBePISA website's 'PISA Query' page. The header includes the Protein Data Bank in Europe logo and navigation links for Services, Research, Training, and About us. The main content area is titled 'PISA Query' and features a 'Submission Form' and 'Structure Analysis' section. Under 'Structure Analysis', there are options for 'PDB entry (2am)' and 'Coordinates file'. The 'Analysis' section is set to '2 amino acid chains and 2 ligands in ASU', with 'Most probable assembly' set to '2mer' and 'Process ligands' set to 'ASP'. The 'Processing mode' is set to 'Auto'. Below the query options, there are buttons for 'Interface', 'Monomers', and 'Assemblies'. The footer contains information about the PDBePISA project, including its location at EMBL EBI, Wellcome Genome Campus, and copyright details.

The screenshot shows the 'PISA Assembly List' page on the PDBePISA website. The page title is 'PISA Assembly List' and it displays 'Probable Assemblies in PDB 12as crystal'. The assembly is identified as 'Space symmetry group P 1 2 1 Resolution 2.39 Å' and is associated with the entry 'ASPARAGINE SYNTHETASE MUTANT C35A COMPLEXED WITH L-ASPARAGINE AND ASP'. The page includes a 'Complex' analysis section and a 'NOTE' regarding the assembly. Below the note, there is a table with columns for 'PDB set name', 'Formula', 'Composition', 'H', 'Biomol', 'State', 'Surface', 'Ruled', 'ASP', and 'ASP²'. The table lists two assemblies: 'PDB set 1 in 1 of total 1' and 'PDB set 1 in 1 of total 1'. The footer contains the same navigation and contact information as the previous screenshot.

The screenshot shows a detailed list of PISA assemblies. The table has columns for 'PDB set name', 'Formula', 'Composition', 'H', 'Biomol', 'State', 'Surface', 'Ruled', 'ASP', and 'ASP²'. The list contains 48 entries, each representing a different assembly of the protein complex. The entries are numbered from 1 to 48 and include details such as the number of molecules (n) and the number of amino acids (a). The footer contains the same navigation and contact information as the previous screenshots.

48	CB	VAL 4	34,107	34,230	25,142	1.00	47.83		

Now, if you wish to download say will get in PDB format. Now, the point is here that if so, incidentally this 1 to AS contains only two chains, A and B, it is a homodimer and that homodimer presents in the PDB. So, as such, there will be no difference between the structure you are downloading and original PDB structure.

But if it is the case that the original structure is a monomer and then basically you are then basically you are analyzing that one using PISA then PISA suggests that it may be dimer, it may be tetramer then corresponding to that analysis if you download then you will get the symmetry-related information and also the that particular say if it is predicted as dimer or tetramer then that dimer you can able to download, tetramer you can able to download, so those things you can able to download. So, those information's are possible.

So, let me see any other protein structure. So, 2 amino acid chains in PDB and 4 ligands in asymmetric unit. And processing ligands heme and oxygen do you wish to process, if no, then I am unchecking this, and then I am going to the assemblies. So, it is taking a little bit time because it is a web service. So based upon the workload and the load of this particular PDB ID that I have selected, so it will take some time. So, it is telling that 6 processors are being utilized. CPU 1 through 6.

I got the result. So, you remember that initially, the suggestion there are two chains in a PDB. So, its PDB ID is 6BV5. It is human oxyhemoglobin. So, two chains was there initially now it is predicting that actually the size is 4, so it is A2B2 which means 2 A chains and 2 B chains. Now, if I view, I will see there are four chains. See, there are four chains with four

different colors. Now, if I go to the which cartoons you can see, the solid spheres are indicating the hetero atoms. So, no need to look at that one.

So, you see there are four chains. But actually, in PDB there are two chains. So, you may be misled, by the information at the PDB. That is why, we are basically discussing this particular topic. And also, we are proposing that the kind of work you can do and the algorithm which exists to take care of this fact.

Means, say you take the information of space group you need cell atomic coordinate for the crystal structures, and the new predict what are the most likely biological assembly and what are the coordinates for that one. So, you generate the total quaternary structure out of the protein crystals. So that is what we have discussed.

(Refer Slide Time: 31:25)

The slide is titled "Web services" in blue text. It lists three services with their URLs:

- PDBePISA (Proteins, Interfaces, Structures and Assemblies) <https://www.ebi.ac.uk/pdbe/pisa/>
- PIQSi https://shmoo.weizmann.ac.il/elevy/piqsiV6/piqsi_links.cgi
- IPACdb <http://pallab.serc.iisc.ernet.in/IPACdb/>

The slide has a decorative background with a blue and green triangle on the right and a dark blue arch at the bottom. At the bottom of the slide, there is a footer with the name "Pralay Mitra" and logos for IIT Bombay and NPTEL.

Now, going back to the slide, actually. So, similar to that IPACdb you can check it out in the website. So, this also provides a nice interface, but the update has stopped for a long for this IPACdb. So that is it. Thank you very much.
