**Laplace Transform Example Problems – Evaluation of Laplace Transform, Inverse LT through Partial Fraction**

Hello welcome to another module in this massive open online course. So, you are looking at the Laplace transform and the properties and applications of Laplace transform.

(Refer Slide Time: 00:29)

Let us now look at example problems to better understand the Laplace transform. So, what you want to now do in this module and also probably. The next few modules is look at example problems for the properties and application of the Laplace transform ok.

And so, let us look at example problem number 1 let us start with something simple. So, I have a signal  $x(t)$  equals  $e^{2t}u(t)$  where you need you  $t$  is the unit step function, plus  $e$  raise to minus 3  $u$  minus  $t$ , now we want to compute the Laplace transform or evaluate the Laplace transform of this signal correct. So, we want evaluate a Laplace transform of  $e$  raised to 2  $t$   $u$   $t$  plus  $e$  raise to minus 3  $t$   $u$  minus 3 and we also want to find the ROC of course, the Laplace transform is incomplete without the ROC.

So, now let me use the following properties we already know that the Laplace transform of  $e^{-at}u(t)$ ; this is  $1/(s+a)$  and ROC is real part of  $s$  greater than  $-a$  and the Laplace transform of  $e^{-at}u(-t)$  is also  $1/(s+a)$ , but the ROC equals real part of  $s$  less than  $-a$ .

(Refer Slide Time: 03:04)

The image shows a digital whiteboard with the following handwritten content:

- At the top right, a general formula:  $s+a$  above  $ROC = \text{Re}\{s\} < -a$ .
- In the middle, the derivation for the first signal:  $e^{2t}u(t) = e^{-at}u(t)$  with  $a = -2$  below it. This is followed by an arrow pointing to  $\frac{1}{s-2}$  and  $\text{Re}\{s\} > 2$ .
- Below that, the derivation for the second signal:  $e^{-3t}u(-t) \leftrightarrow \frac{1}{s+3}$  and  $\text{Re}\{s\} < -3$ .
- At the bottom, the combined result:  $NET\ ROC = \text{Re}\{s\} > 2 \cap \text{Re}\{s\} < -3$ .

And therefore now, if you look at this signal  $e^{2t}u(t)$  this is equal to  $e^{-at}u(t)$  where  $a$  equals  $-2$  which means the Laplace transform is  $1/(s-2)$  the ROC is real part of  $s$  greater than  $-a$  that is real part of  $s$  greater than  $2$ . On the other hand, let us look at the other signal that is  $e^{-3t}u(-t)$  which is equal to  $e^{-at}u(-t)$  with  $a$  equals  $3$ .

So, implies the Laplace transform of this signal can be obtained as  $1/(s+a)$  where  $a$  equals  $-2$  which means the Laplace transform is  $1/(s-2)$  the ROC is real part of  $s$  greater than  $-a$  that is real part of  $s$  greater than  $2$ . On the other hand, let us look at the other signal that is  $e^{-3t}u(-t)$  which is equal to  $e^{-at}u(-t)$  with  $a$  equals  $3$ .

So, the Laplace transform is  $1/(s+3)$  the real part of  $s$  greater than or real part of  $s$  less than, because this is a left handed signal remember  $u(-t)$  is equal to  $0$  for  $t$  greater than  $0$  therefore, this is a left handed signal. So, the region of convergence is of the form ROC that is real part of  $s$  is less than something.

So, here the ROC is of the form real part of s is less than minus 3, ROC is less than minus a equals 3 here. And therefore, ROC is real part of s less than minus 3. Now you see the net ROC of the signal will be the intersection of these 2 ROCs therefore, the NET ROC equals real part of s greater than 2 intersection with real part of s less than minus 3, and you can see that the intersection of these 2 signals there is real part of s greater than 2 and real part of s less than minus 3 is basically 5 this is an empty set. There is no value of s where both the Laplace transform of both these signals that is e raise to 2 t u t, and e raise to minus 3 t u minus 3 converge. And therefore, correct e raise 2 to t u t and e raise to the power minus 3 t u minus t converge and therefore, which implies that the ROC is the empty set which means that the Laplace transform of this signal does not exist ok.

(Refer Slide Time: 05:59)

The image shows a whiteboard with handwritten mathematical work. At the top, there is a blue scribble and the text  $a = -2$ . Below that, a blue arrow points to the equation  $\frac{1}{s-2}, \text{Re}\{s\} > 2$ . In the middle, a red arrow points to the equation  $e^{-3t} u(-t) \leftrightarrow \frac{1}{s+3}, \text{Re}\{s\} < -3$ . Below this, the intersection of the two ROCs is calculated:  $\text{NET ROC} = \text{Re}\{s\} > 2 \cap \text{Re}\{s\} < -3$ . This is followed by an equals sign and a circled phi symbol ( $\emptyset$ ). A blue arrow points from the phi symbol to the text "Empty set". Below that, two blue arrows point to the text "ROC's do NOT overlap" and "LT does NOT exist".

So, this intersection correct this intersection equals phi which is basically empty set correct, this is the empty set implies that implies basically ROCs do not overlapped implies that Laplace transform exist does not exist for this signal.

(Refer Slide Time: 06:46)

$\Rightarrow$  ROCs do NOT overlap  
 $\Rightarrow$  LT does NOT exist

$$x(t) = e^{-3t}u(t) + e^{2t}u(-t)$$

$\downarrow$   $a=3$                        $\downarrow$   $a=-2$

$$\frac{1}{s+3} - \frac{1}{s-2}$$

$\text{ROC} = \text{Re}\{s\} > -3$                        $\text{Re}\{s\} < 2$

$$\text{ROC} = \text{Re}\{s\} > -3 \cap \text{Re}\{s\} < 2$$

$$= -3 < \text{Re}\{s\} < 2$$

Let us look at another example for instance the same thing. Let us now look at the signal just modify that a little bit, let us now look at the signal  $x(t) = e^{-3t}u(t) + e^{2t}u(-t)$ . Now the Laplace transform of  $e^{-3t}u(t)$  is  $\frac{1}{s+3}$ , now this is  $e^{-at}u(t)$  with  $a=3$ . So, this is  $\frac{1}{s+3}$  ROC is a real part of  $s$  greater than  $-3$  this is a right handed signal, because you  $u(t)$  is basically 0 for  $t < 0$ .

So, this is a right handed signal. So, ROC of the is of the form real part of  $s$  greater than  $-3$  real part of  $s$  greater than  $-3$ , and  $e^{2t}u(-t)$  this is a left handed signal with basically with Laplace transform, I think here  $e^{-at}u(-t)$  the Laplace transform is  $-\frac{1}{s-a}$ . So, I will just correct this this is  $-\frac{1}{s-2}$  ok.

And therefore, the Laplace transform  $e^{2t}u(-t)$  is basically  $-\frac{1}{s-2}$  and  $e^{-2t}u(-t)$  is  $\frac{1}{s+2}$ . So, this is  $\frac{1}{s-2}$  and  $-\frac{1}{s-2}$  and the ROC is real part of  $s$  basically real part of  $s$  less than  $-2$  that is real part of  $s$  less than, so this corresponds this corresponds to a equals  $-2$  this corresponds to a equals  $3$ .

So, real part of  $s$  less than  $-2$  which means real part of  $s$  less than  $2$ , which implies the net ROC equals the intersection of these 2 ROCs that is a real part of  $s$  greater than  $-3$  intersection, real part of  $s$  less than  $2$  which is equal to well this is equal to

minus. So, you can clearly see intersection is minus 3 less than real part of s less than 2, and the NET Laplace transform x s equals 1 over s plus 3 minus 1 over s minus 2.

(Refer Slide Time: 09:26)

Handwritten mathematical derivation on a whiteboard:

$$X(s) = \frac{1}{s+3} - \frac{1}{s-2}$$

Annotations for the first term:  $\text{ROC} = \text{Re}\{s\} > -3$

Annotations for the second term:  $\text{Re}\{s\} < 2$

$$\text{ROC} = \text{Re}\{s\} > -3 \cap \text{Re}\{s\} < 2$$

$$= -3 < \text{Re}\{s\} < 2$$

$$X(s) = \frac{-5}{(s+3)(s-2)}$$

Final ROC:  $-3 < \text{Re}\{s\} < 2$

So, therefore, x s is equal to well s minus 2 minus s minus 3 that is minus 5 divided by s plus 3 into s minus 2. And the ROC for this is minus 3 less than real part of s less than that is the corresponding ROC region of convergence with this Laplace transform.

So, the Laplace transform is minus 5 or s plus 3 into s minus through s minus 2, and the corresponding ROC is minus 3 less than real part of this less than 2 all right.

(Refer Slide Time: 10:18)

Handwritten mathematical derivation on a whiteboard:

ROC:  $-3 < \text{Re}\{s\} < 2$

---

Ex #2:  $x(t) = e^{-2t}(u(t) - u(t-5))$

$$= e^{-2t}u(t) - e^{-2t}u(t-5)$$

Annotations for the first term:  $e^{-2t}u(t) \leftrightarrow \frac{1}{s+2}$ ,  $\text{ROC}: \text{Re}\{s\} > -2$

Second term:  $e^{-2t}u(t-5)$

Now, let us look at another example this is a example number the second example problem to understand how to evaluate the Laplace transform. So, I have  $x(t)$  equals  $e^{-2t} u(t-5)$  this is equal to now. Let us look at this let me simply write this as  $e^{-2t} u(t) - e^{-2t} u(t-5)$ .

Now,  $e^{-2t} u(t)$  this has the Laplace transform this is a right handed signal. So, this has the Laplace transform well a equals, this is  $e^{-st}$  raised to the power minus at  $u(t)$  with  $a$  equal to 2. So, this is of has the Laplace transform  $1/(s+2)$  and the ROCs of the form real part of  $s$  greater than minus 2 because this is a right handed signal.

(Refer Slide Time: 11:55)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it says "Ex #2." and defines  $x(t) = e^{-2t} u(t-5)$ . This is then written as  $e^{-2t} u(t) - e^{-2t} u(t-5)$ . The first term is shown to have a Laplace transform of  $1/(s+2)$  with a Region of Convergence (ROC) of  $\text{Re}\{s\} > -2$ . The second term is expanded as  $e^{-2(t-5)} \cdot e^{-10} u(t-5)$ , which is then written as  $e^{-10} \cdot e^{-2(t-5)} u(t-5)$ . This is identified as  $x(t-t_0)$  where  $t_0 = 5$ , and its Laplace transform is shown as  $e^{-10} \cdot e^{-5s} \cdot \frac{1}{s+2}$  with a ROC of  $\text{Re}\{s\} > -2$ .

Now, consider this signal  $e^{-2t} u(t-5)$ , now this can be equivalently written as  $e^{-2t-10} u(t-5)$  correct  $e^{-2t-10}$  times  $e^{-2t-10}$  into  $u(t-5)$ , which is  $e^{-10}$  into  $e^{-2t-10}$  into  $u(t-5)$ .

Now, if you look at this signal  $e^{-2t-10} u(t-5)$ , this is of the form  $x(t-t_0)$  where  $t_0$  equals 5. And  $x(t)$  is  $e^{-2t}$  into  $u(t)$ . So, this is  $x(t)$  this is a signal  $x$ , this is a signal  $x(t)$  delayed this is a signal  $x(t)$  where  $x(t)$  is  $e^{-2t}$  into  $u(t)$  delayed by  $t_0$  where  $t_0$  equals 5.

Hence we know that the Laplace transform  $x(t-t_0)$  is  $e^{-st-t_0s}$  into  $X(s)$  therefore, the Laplace transform of this will be, well first we have the

constant  $e$  raise to minus 10 into  $e$  raise to minus  $s$   $t$  naught  $t$  naught is 5. So, this will be  $e$  raise to minus 5  $s$  divided by into 1 over  $s$  plus 2 is a Laplace transform of  $e$  raise to 2 minus 2  $t$   $u$   $t$  and the ROC will be again real part of  $s$  greater than minus 2.

(Refer Slide Time: 13:43)

The image shows a whiteboard with handwritten mathematical work. At the top, there is a line:  $= e^{-10} \cdot e^{-2(t-5)} u(t-5) \leftrightarrow e^{-10} \cdot e^{-5s} \cdot \frac{1}{s+2}$ . Below this, it is noted that  $x(t-t_0)$  with  $t_0 = 5$  and  $\text{Re}\{s\} > -2$ . A horizontal line separates this from the main derivation. The main derivation shows:  $X(s) = \frac{1}{s+2} - \frac{e^{-10} \cdot e^{-5s}}{s+2}$ . This is then simplified to  $\frac{1}{s+2} (1 - e^{-5(s+2)})$ . Below this, the region of convergence is stated as  $\text{ROC: } \text{Re}\{s\} > -2$ .

Therefore the final Laplace transform will be that is  $x$   $s$  will be the sum of the 2 Laplace transforms 1 over  $s$  plus 2 plus  $e$  raise to minus 10  $e$  raise to minus 5  $s$  divided by  $s$  plus 2, which is equal to 1 over  $s$  plus 2, I am sorry this will be a minus 1 minus  $e$  raise to minus 5 into  $s$  plus 2. And the ROC will be real part of  $s$  greater than minus 2 this is the final region of convergence for this problem this is the ROC for this problem ok.

(Refer Slide Time: 14:41)

$$= \frac{1}{s+2} (1 - e^{-5(s+2)})$$

$$\text{ROC: } \text{Re}\{s\} > -2$$

ex #3: LT of  $e^{-at} \cos(\omega_0 t) u(t)$

$$\cos(\omega_0 t) u(t) \leftrightarrow \frac{s}{s^2 + \omega_0^2}$$

$$\text{ROC: } \text{Re}\{s\} > 0$$

Now, let us do another example we want to evaluate the Laplace transform of the following function, that is LT of  $e^{-at} \cos(\omega_0 t) u(t)$ , and remember we already know that the Laplace transform of  $\cos(\omega_0 t) u(t)$  is  $s / (s^2 + \omega_0^2)$ . So, we already know that the Laplace transform of  $\cos(\omega_0 t) u(t)$  is  $s / (s^2 + \omega_0^2)$  and the ROC for this will be or ROC for this is that the real part of  $s$  is greater than 0 is the right handed signal.

(Refer Slide Time: 15:55)

$$e^{-at} x(t) \leftrightarrow X(s+a)$$

$$e^{-at} \cos(\omega_0 t) u(t) \leftrightarrow \frac{(s+a)}{(s+a)^2 + \omega_0^2}$$

$$\text{ROC: } \text{Re}\{s\} + a > 0$$

$$\Rightarrow \boxed{\text{Re}\{s\} > -a}$$

LT  $X(s)$

Now, remember we have the property recall we have the property  $e^{-at}$  has the Laplace transform  $X(s)$  of  $s + a$  correct. So, where  $X(s)$  is a Laplace transform, that is if  $x(t)$  has the Laplace transform  $X(s)$  correct, then  $e^{-at}x(t)$  has a Laplace transform  $X(s + a)$  therefore,  $e^{-at} \cos(\omega_0 t) u(t)$  will naturally have the Laplace transform  $X(s + a)$  that is replace  $s$  by  $s + a$   $s^2 + \omega_0^2$  plus  $\omega_0^2$ .

And the region of convergence will be naturally real part of  $s + a > 0$  real part of  $s$  implies real part of  $s > -a$ , this is the region of  $a$ . So, this is the Laplace transform that is  $X(s)$  and this is the region of convergence that is real part of  $s > -a$  the Laplace transform is  $X(s + a)$  that is  $s + a$  divided by  $s^2 + \omega_0^2$  plus  $\omega_0^2$  all right.

(Refer Slide Time: 17:45)

EX #4:

$$X(s) = \frac{3s+5}{s^2+3s+2}$$

ROC:  $\text{Re}\{s\} < -2$

Inverse Laplace Transform  
 $x(t) = ?$

Rational Function  
 $m = 1$     $n = 2$     $m < n$   
 $\Rightarrow$  Proper Rational Function

$$X(s) = \frac{(3s+5)}{(s+2)(s+1)}$$

Let us now do another problem, we have the Laplace transform equals given the Laplace transform  $X(s)$  equals  $3s + 4$  divided by  $s^2 + 3s + 2$  the ROC is real part of  $s < -2$ , now we want to evaluate the inverse Laplace transform that is what is the signal  $x(t)$ .

Now, the inverse Laplace now we want to evaluate the inverse Laplace transform, that is corresponding to  $X(s)$  the given Laplace transform the signal the Laplace transform  $X(s)$ , we want to find that what is the inverse Laplace transform that is we want to reconstruct the corresponding signal  $x(t)$ . Now observe first that this is a rational function, that is it is

a numerator polynomial and divided by denominator polynomial, further degree of numerator polynomial is 1 degree of denominator polynomial is 2 therefore, we have m less than n which implies as a proper implies as a proper rational function therefore, I express this as partial fractions.

Now, if you look at this I can write X s as 3 s plus 4 divide sorry 3 s plus let me just change this slightly there is 3 s plus 5. So, I can write x s as 3 s plus 5 divided by s square plus 3 s plus 2 the roots are minus 2 and minus 1. So, I can write this as s plus 2 remember the factors are s plus 2 and s plus 1 so, I can write this as plus 2 and s plus 1 and therefore, now the poles p 1 equals minus 2 p 2 equals minus 1.

(Refer Slide Time: 20:21)

$$X(s) = \frac{(3s+5)}{(s+2)(s+1)} \rightarrow \text{Poles}$$

$$P_1 = -2, P_2 = -1$$

$$z_1 = -\frac{5}{3}$$

---

Partial Fraction Expansion,

$$X(s) = \frac{C_1}{s+2} + \frac{C_2}{s+1}$$

$$C_1 = (s+2)X(s) \Big|_{s=-2}$$

$$= \frac{3s+5}{s+2} \Big|_{s=-2}$$

In fact, 0 minus 5 by 3, 3 s plus y equal to 0 so, the 0 is minus 5 by 3. So, these are the poles correct, and these are the poles of the rational transfer function therefore, I can expressing using partial fractions therefore, using the partial fraction expansion I can write X s equals 1 sum constant C 1 divided by s plus 2 plus sum constant C 2 divided by s plus 1. Now the way to evaluate C 1 we already know this is well s plus 2 that is s minus p 1 times X s evaluated at s equal to p 1 evaluated at s equal to minus, 2 which is basically x plus s plus 2 into x s is 3 s plus 5 divided by s plus 2.

(Refer Slide Time: 21:55)

The image shows a digital whiteboard with handwritten mathematical work. At the top, there is a toolbar with various icons. The main content consists of the following steps:

$$= \frac{3s+5}{s+1} \Big|_{s=-2}$$
$$= \frac{-1}{-1} = 1$$
$$\boxed{C_1 = 1}$$
$$C_2 = (s+1)X(s) \Big|_{s=-1}$$
$$= \frac{3s+5}{s+2} \Big|_{s=-1}$$

---

$$= \frac{2}{1} = 2$$

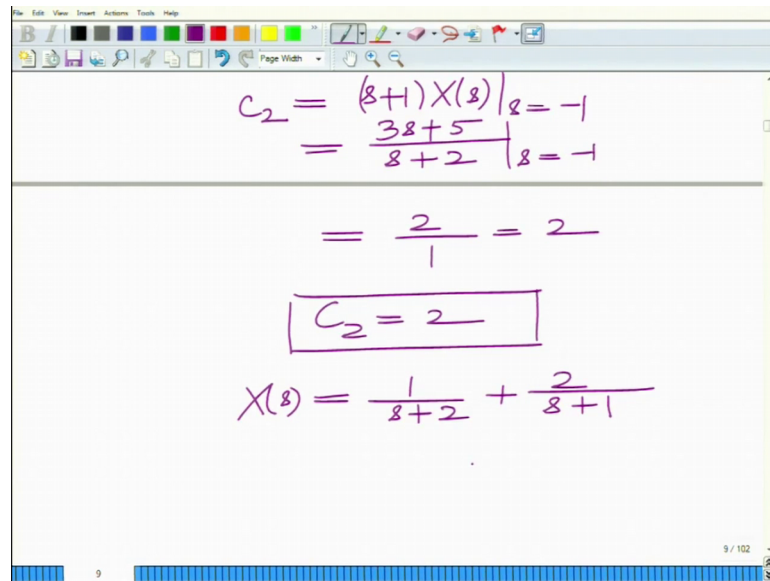

At the bottom right of the whiteboard, there is a small text "9 / 102".

Evaluated at  $s$  equal to 3  $s$  plus 5 divided by  $s$  plus 1 evaluated at  $s$  equal to minus 2 that is minus 1 divided by minus 1 which is equal to 1.

Therefore  $C_1$  is equal to 1, and  $C_2$  that  $C_1$  is equal to 1 the coefficient  $C_1$  corresponding to the pole  $p_1$  equals minus 2 partial fraction expansion of  $X(s)$  is  $C_1$  equals 1. Now  $C_2$  similarly can be evaluated in a similar fashion 1 can evaluate  $C_2$  as  $s$  plus 1 into  $X(s)$  evaluated at  $s$  equal to minus 1  $s$  plus 1 into  $X(s)$ . Now you can see this is equal to 3  $s$  plus 5 divided by  $s$  plus 2 that is evaluated at  $s$  equal to minus 1 which is basically a 2 divided by 1 which is equal to 2 ok.

(Refer Slide Time: 23:03)

$$C_2 = \lim_{s \rightarrow -1} (s+1)X(s)$$

$$= \lim_{s \rightarrow -1} \frac{3s+5}{s+2}$$

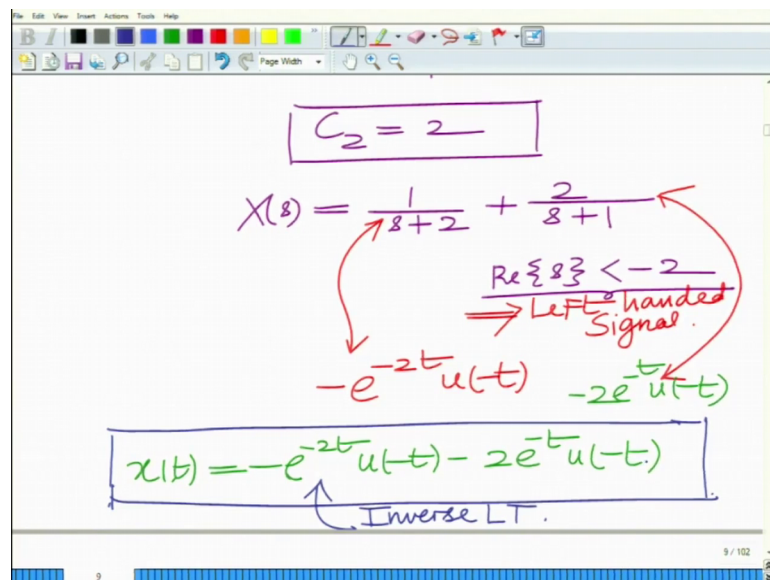

$$= \frac{2}{1} = 2$$

$$\boxed{C_2 = 2}$$

$$X(s) = \frac{1}{s+2} + \frac{2}{s+1}$$

And therefore,  $C_2$  equal to 2 and therefore, from the partial fraction expansion we have  $X(s)$  equals  $\frac{1}{s+2} + \frac{2}{s+1}$ , now you can see the ROC is real part of  $s$  less than minus 2, which basically implies that it is a left handed signal ok.

(Refer Slide Time: 23:26)

$$\boxed{C_2 = 2}$$

$$X(s) = \frac{1}{s+2} + \frac{2}{s+1}$$

$\text{Re}\{s\} < -2$   
 $\Rightarrow$  LEFT handed Signal.

$$-e^{-2t}u(t) \quad -2e^{-t}u(-t)$$

$$\boxed{x(t) = -e^{-2t}u(t) - 2e^{-t}u(-t)}$$

Inverse LT.

When ROC is of the form real part of  $s$  less than  $\sigma_{max}$ ; so this will be of the form minus  $e$  raise to minus  $2t$   $u$  minus  $t$  this is of the form that is the time domain signal corresponding  $\frac{2}{s+1}$  is minus  $2e$  raised to minus  $t$   $u$  minus  $t$  therefore NET signal  $x$  of  $t$ , will be minus  $e$  raise  $2$  minus  $t$  or let me just write it clearly  $x$   $t$  is minus  $e$

raise to minus  $t$   $u$  minus  $t$  minus  $2 e$  minus  $t$   $u$  minus  $t$  and that is the NET. So, that is the net time domain signal or the inverse Laplace.

That is the expression for the inverse Laplace transform. So, all right in this module we have seen some examples, the example problems with the Laplace transform how to evaluate the Laplace transform, as well as the inverse Laplace transform, we will continue looking at these examples other examples in the subsequent modules.

Thank you very much.
