Fourier Transform - Parseval's Relation, Frequency Response of Continuous Time LTI Systems

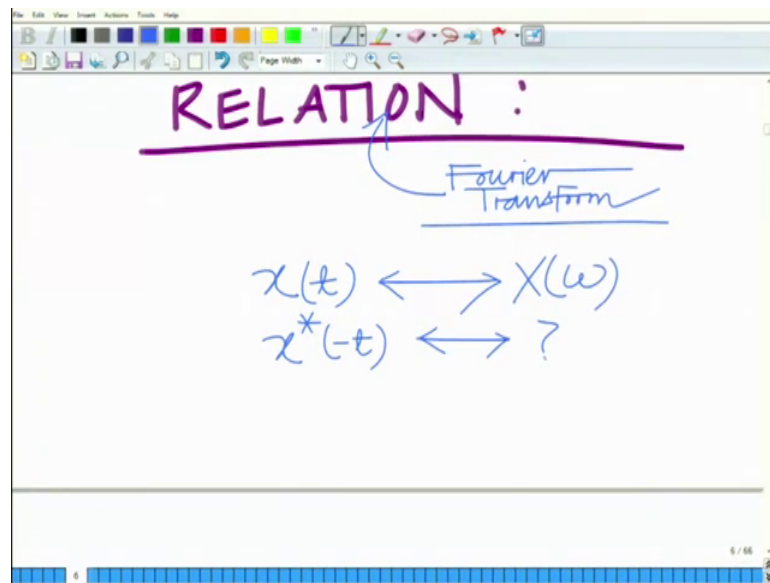

Hello, welcome to another module in this massive open online course. So, we are looking at the Fourier transform for continuous aperiodic signals and its several properties. Let us look at another interesting and important property that is a Parseval's relation and this will bring up a lot of other aspects such as the autocorrelation function and so, on alright.

(Refer Slide Time: 00:32)

So, let us explore the Parseval's; the Parseval's relation for the Fourier transform. You already seen the Parseval's relation or the Parseval's theorem for the discrete Fourier series we want to explain we want to look at it for the Fourier transform.

(Refer Slide Time: 01:13)

Now, first consider a signal $x(t)$ which has the Fourier transform $X(\omega)$. Now we want to look at first what is the Fourier transform of $x^*(-t)$ what is the Fourier transform of this signal?

(Refer Slide Time: 01:39)

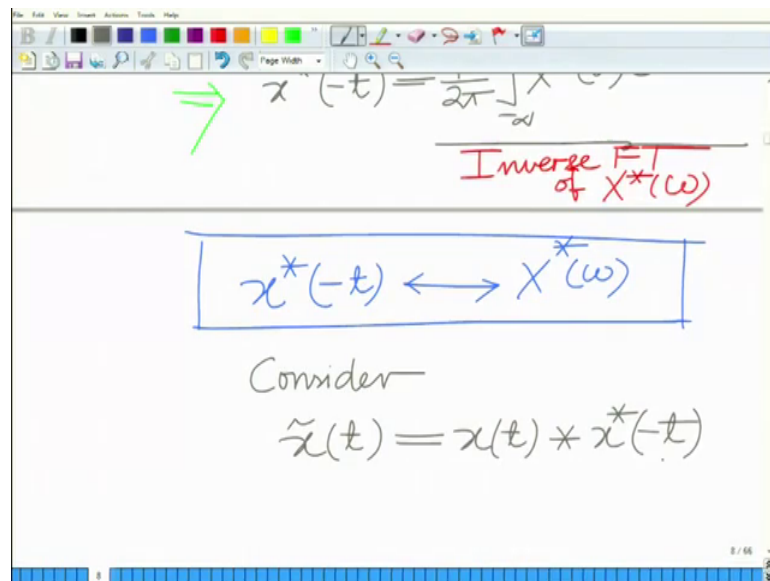

$$x(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} X(\omega) e^{j\omega t} d\omega$$
$$\Rightarrow x^*(t) = \left(\frac{1}{2\pi} \int_{-\infty}^{\infty} X(\omega) e^{j\omega t} d\omega \right)^*$$
$$= \frac{1}{2\pi} \int_{-\infty}^{\infty} X^*(\omega) e^{j\omega t} d\omega$$
$$\Rightarrow x^*(-t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} X^*(\omega) e^{j\omega t} d\omega$$

Now, using the properties of the inverse Fourier transform first you can see that $x(t)$ which is the inversed Fourier transform of capital X of ω this is $\frac{1}{2\pi} \int_{-\infty}^{\infty} X(\omega) e^{j\omega t} d\omega$ which implies that if you take the conjugate the complex conjugate on both sides.

Then you have $x^*(t)$ equals $\frac{1}{2\pi} \int_{-\infty}^{\infty} X^*(\omega) e^{j\omega t} d\omega$. If you now take the conjugate operation inside; this will be $\frac{1}{2\pi} \int_{-\infty}^{\infty} X(\omega) e^{-j\omega t} d\omega$.

And now if you replace t by $-t$ this implies that $x^*(-t)$ is $\frac{1}{2\pi} \int_{-\infty}^{\infty} X(\omega) e^{j\omega t} d\omega$.

(Refer Slide Time: 03:08)

And now you can see this right hand side is nothing, but the inverse Fourier transform of $X^*(\omega)$. So, you can see $x^*(-t)$ is basically the inverse Fourier transform of $X^*(\omega)$.

So, therefore, one can conclude that $x^*(-t)$ has the Fourier transform $X^*(\omega)$. So, this is the first property that we want to start with that is $x^*(-t)$ has the Fourier transform $X^*(\omega)$.

Now we define the function consider now $\tilde{x}(t)$ defined as $x(t)$ convolved with $x^*(-t)$. So, we are taking $x(t)$ convolving it with $x^*(-t)$. So, $\tilde{x}(t)$ is $x(t)$ convolved with $x^*(-t)$.

Now naturally what we have seen is the convolution if you seen an important property the Fourier transform previously that is the convolution in time domain is basically that is

the signal which is the convolution of two signals in the time domain has a Fourier transform which is basically the multiplication is obtained by the multiplication of the Fourier transforms of these two signals.

(Refer Slide Time: 04:46)

The image shows a whiteboard with the following handwritten equations:

$$\tilde{x}(t) = x(t) * x^*(-t)$$

$$\Rightarrow \tilde{X}(\omega) = \mathcal{F}\{x(t)\} \mathcal{F}\{x^*(-t)\}$$

$$= X(\omega) \cdot X^*(\omega)$$

$$\tilde{X}(\omega) = |X(\omega)|^2$$

A box is drawn around the final two equations, with a double-headed arrow between $\tilde{x}(t)$ and $|X(\omega)|^2$, indicating a Fourier transform pair.

Therefore, now, this implies if you take the Fourier transform of $\tilde{x}(t)$ you have $\tilde{X}(\omega)$ it is a multiplication of the Fourier transform of $x(t)$ times the Fourier transform of $x^*(t)$.

But the Fourier transform of $x(t)$ is $X(\omega)$ and the Fourier transform of $x^*(t)$ is $X^*(\omega)$ as we have seen above; So, this is $X(\omega)$ into $X^*(\omega)$ equals that is; so, we have a magnitude $|X(\omega)|^2$.

So, we have $\tilde{X}(\omega) = |X(\omega)|^2$ which means $\tilde{x}(t)$ which is the convolution of $x(t)$ with $x^*(t)$ has the Fourier transform magnitude $|X(\omega)|^2$.

(Refer Slide Time: 05:54)

$$\begin{aligned}\tilde{x}(t) &= x(t) * x^*(-t) \\ &= \int_{-\infty}^{\infty} x(\tau) \cdot x^*(-(t-\tau)) d\tau \\ \tilde{x}(t) &= \int_{-\infty}^{\infty} x(\tau) x^*(\tau-t) d\tau \\ \text{Set } t &= 0 \\ \Rightarrow \tilde{x}(0) &= \int_{-\infty}^{\infty} x(\tau) \cdot x^*\end{aligned}$$

Now, let us look at what is let us again expand $\tilde{x}(t)$ that is the convolution of x of t with x conjugate of minus t .

Which is basically I can write it as minus infinity to infinity x of τ times x conjugate of minus τ minus t $d\tau$ correct; this is the definition of a this follows from the definition of the convolution. So, this is minus infinity to infinity x of τ x conjugate t minus τ $d\tau$ which implies setting t equal to 0.

Which implies you have $\tilde{x}(0)$ equals minus infinity to infinity x of τ into x conjugate of I am sorry this is x of this is x of τ into x conjugate of x conjugate of minus I am sorry this is x of τ into x conjugate of minus τ minus τ minus t $d\tau$.

So, this will be τ minus t and your set t equal to 0.

(Refer Slide Time: 07:40)

The image shows a digital whiteboard with handwritten mathematical equations. At the top, the equation $\tilde{x}(0) = \int_{-\infty}^{\infty} x(\tau) \cdot x^*(\tau) d\tau$ is written, which is then simplified to $= \int_{-\infty}^{\infty} |x(\tau)|^2 d\tau$. Below this, the same equation $\tilde{x}(0) = \int_{-\infty}^{\infty} |x(\tau)|^2 d\tau$ is written again, with a red arrow pointing from the text "Energy of signal." to the integral. At the bottom, the equation $\tilde{x}(t) = \mathcal{F}^{-1} \{ |X(\omega)|^2 \}$ is written. The whiteboard interface includes a toolbar at the top and a status bar at the bottom showing "10 / 66".

So, this x of τ into x conjugate of τ $d\tau$ which is integral minus infinity to infinity magnitude x x τ square $d\tau$ which is nothing, but the energy of the signal; so, what you can see is $\tilde{x}(0)$ equals minus infinity to infinity magnitude x τ square $d\tau$ that is this is I equal to the this is equal to the energy of the signal.

That is \tilde{x} which is the convolution of x t and x conjugate of minus t if you evaluate it at t equal to 0 ; that is $\tilde{x}(0)$ this is this is simply gives me the energy of the signal. Now, we also know that $\tilde{x}(t)$ is the inverse Fourier transform of magnitude x of ω square; that is what we had shown above we. So, from this property that is if you look at this property $\tilde{x}(t)$ is the inverse Fourier transform magnitude of x of ω square.

(Refer Slide Time: 08:43)

The image shows a whiteboard with handwritten mathematical equations. At the top, there is a red arrow pointing to the upper limit of the first integral, labeled "Energy of signal." The equations are as follows:

$$\tilde{x}(t) = \mathcal{F}^{-1} \{ |X(\omega)|^2 \}$$
$$\Rightarrow \tilde{x}(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} |X(\omega)|^2 e^{j\omega t} d\omega$$

Set $t = 0$

$$\Rightarrow \tilde{x}(0) = \frac{1}{2\pi} \int_{-\infty}^{\infty} |X(\omega)|^2 d\omega$$

So, we have $\tilde{x}(t)$ equals IFT or basically the inverse of the Fourier transform of magnitude $|X(\omega)|^2$; this implies that $\tilde{x}(t)$ is $\frac{1}{2\pi}$ times the integral from minus infinity to infinity of magnitude $|X(\omega)|^2 e^{j\omega t} d\omega$.

Now set equal to 0 once again and this implies $\tilde{x}(0)$ equals $\frac{1}{2\pi}$ times the integral from minus infinity to infinity of the magnitude $|X(\omega)|^2 d\omega$. So, we have two relations here; we have $\tilde{x}(0)$ equals the integral from minus infinity to infinity of magnitude $|X(\omega)|^2 d\omega$.

And we also have $\tilde{x}(0)$ equals let us call this relation 2, you also have $\tilde{x}(0)$ equals $\frac{1}{2\pi}$ times the integral from minus infinity to infinity of magnitude $|X(\omega)|^2 d\omega$.

(Refer Slide Time: 10:01)

From (1), (2) we have

$$\int_{-\infty}^{\infty} |x(t)|^2 dt = \frac{1}{2\pi} \int_{-\infty}^{\infty} |X(\omega)|^2 d\omega$$

Parseval's Theorem
Parseval's Relation

Energy of $x(t)$

Energy of $X(\omega)$
Scaling Factor = $\frac{1}{2\pi}$

So, from 1 and 2 we have basically the energy of the signal minus infinity to infinity magnitude x tau square d tau or magnitude x t square d t equals 1 over 2π integral minus infinity to infinity magnitude X omega square d of d omega. And this is basically that is the energy in the time domain equals the energy in the frequency domain and this. So, this is basically your Parseval's this is basically the Parseval's theorem or the Parseval's relation.

This is the energy of x t this is the energy now you can see this is the energy of x omega except for a scaling factor of 1 over 2π . Notice that there is a scaling factor of 2π ; so, this is the energy of x omega. So, the we can say energy of x t is basically the energy of x omega that is energy in the time domain equals the energy the frequency domain that is what the Parseval's framework is about.

Except that note that there is a scaling factor of 1 over 2π and this quantity magnitude X omega square this quantity now if you look at this quantity.

(Refer Slide Time: 11:59)

The image shows a whiteboard with handwritten notes. At the top left, the expression $|X(\omega)|^2$ is written. To its right, the text "Energy spectral Density of $x(t)$ " is written in purple. A green arrow points from this text to the expression. Below this, the text "Distribution of Energy over spectrum" is written in green. In the center, the equation
$$e = \frac{1}{2\pi} \int_{-\infty}^{\infty} |X(\omega)|^2 d\omega$$
 is written in blue. Below the equation, the text "Integrating ESD over entire Frequency Band. $-\infty$ to ∞ " is written in red.

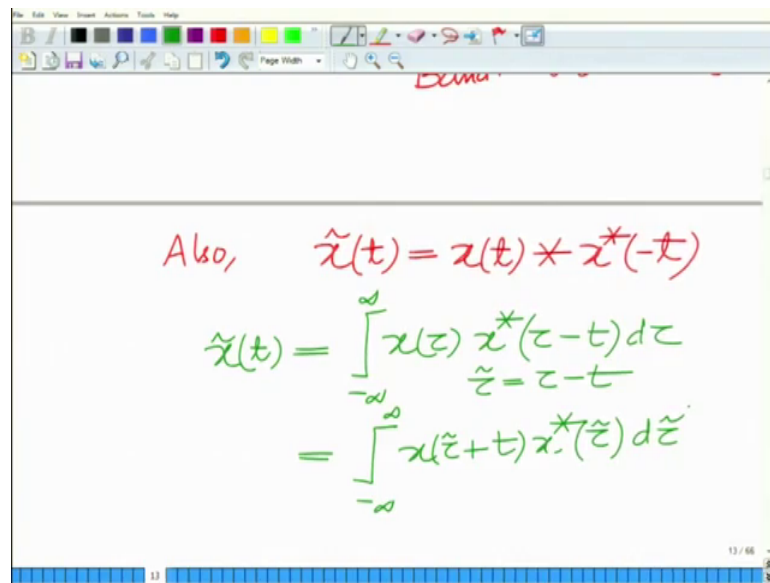

This quantity magnitude X omega square this has a very nice interpretation this is termed as the energy spectral density of $x(t)$. This is termed as the energy spectral density that is the density of the that is you can say this is the distribution of the energy or the density is remember density of an object is the distribution of the mass over the volume.

So, this energy spectral density is the distribution of the energy over the spectrum. That is how is the energy of this signal $x(t)$ distributed in the various frequency bands that is given by this energy spectral density magnitude X of omega square.

And in fact, integrating this energy spectral density over the entire frequency band therefore, naturally gives right; therefore, naturally gives naturally gives the energy of the signal similar to when you integrate the density multiplied by a volume alright and integrate the density that gives the mass of the object; integrating take this taking this energy spectral density multiplying it by an infinitesimally small spectral band and integrating over the spectrum gives the energy of the signal.

And therefore, what you can see of course, there is a scaling factor of 2π . So, this is 1 over 2π minus infinity to infinity magnitude. So, this is basically integrating the Energy Spectral Density ESD over the entire frequency band minus infinity to infinity alright; So integrating the energy spectral density over the entire frequency band that gives the energy of the signal.

(Refer Slide Time: 14:19)

The image shows a screenshot of a presentation slide with a white background and a blue border. At the top, there is a toolbar with various icons for editing and navigation. The word "Exam" is written in red at the top center. Below it, the word "Also," is written in red. The main content consists of three lines of handwritten mathematical equations in green ink. The first line is $\tilde{x}(t) = x(t) * x^*(-t)$. The second line is $\tilde{x}(t) = \int_{-\infty}^{\infty} x(\tau) x^*(\tau - t) d\tau$, with $\tilde{z} = \tau - t$ written below the integral. The third line is $= \int_{-\infty}^{\infty} x(\tilde{z} + t) x^*(\tilde{z}) d\tilde{z}$. In the bottom right corner, there is a small text "13/66".

Now, also observe the following thing; we have $\tilde{x}(t)$ equals $x(t)$ convolved with x conjugate of minus t . Now, therefore we can write it as $\tilde{x}(t)$ equals we already written this as $\tilde{x}(t)$ equals minus infinity to infinity; x of τ x conjugate of τ minus t $d\tau$ or this can also be written as minus infinity to infinity you can say $\tilde{\tau}$ equals τ minus t .

So, this is x of $\tilde{\tau}$ plus t times x conjugate of $\tilde{\tau}$ $d\tilde{\tau}$ and this is termed as the autocorrelation look at this is explores. So, what you are doing is you are multiplying x x $\tilde{\tau}$ correct x $\tilde{\tau}$ or x conjugate $\tilde{\tau}$ with a shifted version of this x conjugate $\tilde{\tau}$ plus $\tilde{\tau}$ plus t .

That is a advanced that is a time advanced version of this by t and you are integrating from minus infinity to infinity. So, this is a measure of the similarity between these two signals x conjugate of $\tilde{\tau}$ and its advanced version that is x of $\tilde{\tau}$ plus t and this is termed as the autocorrelation of the signal x t .

(Refer Slide Time: 16:15)

The image shows a handwritten slide with the following content:

$$= \int_{-\infty}^{\infty} x(t+\tau)x(t) dt$$

↑
Autocorrelation of
Signal $x(t)$

$R_{xx}(t)$

Measure of
Self-similarity
of signal.

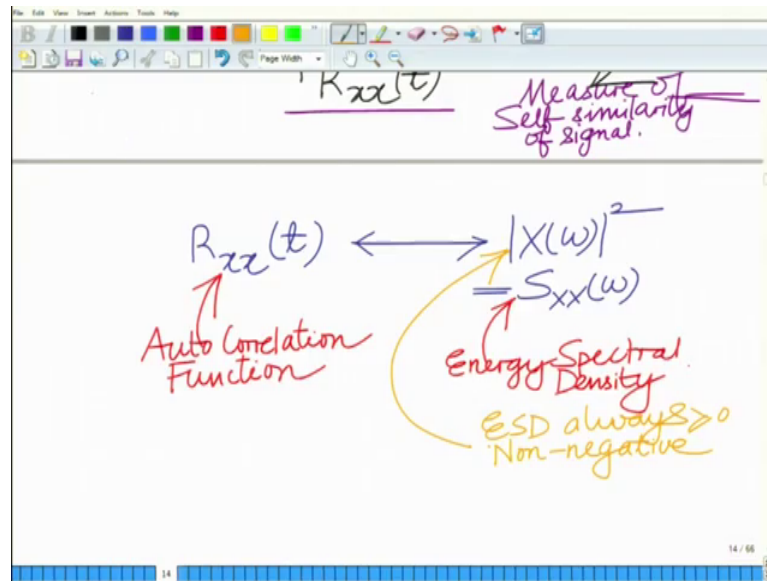

13 / 66

And this is this is termed as the autocorrelation of this signal x of this is termed as the autocorrelation of the signal x of t and this is denoted by R_{xx} of t R_{xx} of t that is autocorrelation of the signal.

And this is the measure of the similarity self similarity measure of the self similarity; there is a measure of the self similarity alright is a measure of the correlation. Also you can say is a measure of the correlation between the signal values separated by a distance of separated by the interval of t right.

How similar is the signal to itself when you shift it or when you advance it by t that is what it means intuitively. And therefore, what you can now see is that this autocorrelation.

(Refer Slide Time: 17:39)

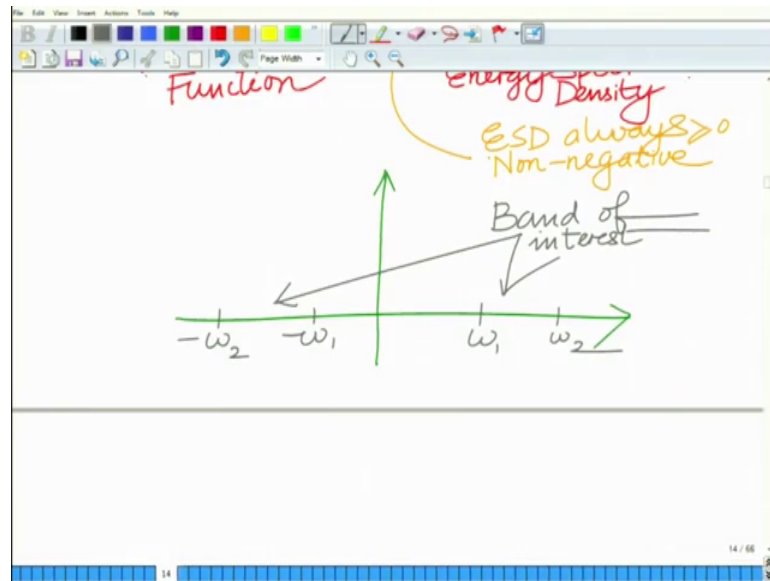

Therefore, what we have shown is that this x tilde t which we have now calling this as the autocorrelation $R_{xx}(t)$ we have shown that this as the Fourier transform X the magnitude X omega square which we also denote now by this notation $S_{xx}(\omega)$ that is the energy spectral density.

So, the energy spectral density is the Fourier transform of the is the Fourier transform of the autocorrelation function. And also note that this its magnitude X of omega square. So, therefore, the ESD is always greater than or equal to 0 always greater than or equal to 0 implies that this is a real quantity and more importantly this is non-negative; the energy spectral density is nonnegative.

And the energy spectral density as I have shown as I have already said basically shows the or it gives us an idea of the distribution of the energy of the signal in the different frequency bands. So, if you want to find the energy of the signal in the particular frequency band; I have to integrate this energy spectral density or the band of interest.

(Refer Slide Time: 19:12)

So, if I have a particular band; I am interested in finding the energy in. So, this is let us say the band ω_1 ω_2 I am interesting I am interested in finding. So, this is my band of interest this is my band of interest.

(Refer Slide Time: 19:45)

The derivation shows the following steps:

$$\begin{aligned} \text{Energy in band} &= 2 \cdot \frac{1}{2\pi} \int_{\omega_1}^{\omega_2} S_{xx}(\omega) d\omega \\ &= 2 \cdot \frac{1}{2\pi} \int_{\omega_1}^{\omega_2} |X(\omega)|^2 d\omega \end{aligned}$$

A note with an arrow pointing to the integral says "Integrating ESD over band of interest".

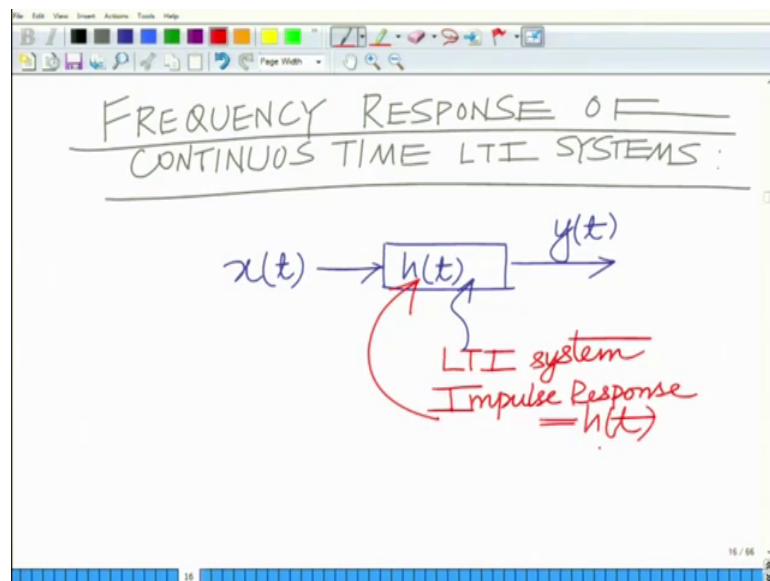

So, energy in the band equals twice because it is symmetric $\frac{1}{2\pi}$ from ω_1 to ω_2 the energy spectral density over that band which is basically nothing, but twice $\frac{1}{2\pi}$ ω_1 to ω_2 magnitude X of magnitude X ω square d ω .

So, basically what we are doing is basically we are integrating the energy spectral density over the band of; we are integrating the energy spectral density over the over the region of interest or over the spectral band of interest ok. So that is the utility of the energy spectral density.

So, basically what we have done is we have defined the autocorrelation function the autocorrelation function is the convolution of x the signal $x(t)$ with x conjugate minus t that has the Fourier transform which is the energy spectral density which; characterizes the distribution of the energy of the signal across the various spectral bands ok.

Similar to the density which characterizes the distribution of the mass of an object over its volume alright; Now, consider the frequency response.

(Refer Slide Time: 21:29)

Now, we want to next we want to explore, we want to explore the frequency response of. So, we want to explore the frequency response of continuous time LTI system; since you are dealing with continuous signals and this case can be obtained.

So, let us say we have a signal $x(t)$ which is input to an LTI system with impulse response $h(t)$.

So, this is my schematic of an LTI system. And the impulse response of this LTI system is $h(t)$ impulse response equals $h(t)$ and therefore, we know that when the signal $x(t)$ is input

of an impulse a system LTI system with impulse response $h(t)$, then the output $y(t)$ is nothing, but the convolution of the input with the impulse response.

(Refer Slide Time: 23:04)

The image shows a whiteboard with handwritten mathematical equations. At the top right, there is a red annotation: "Impulse Response = $h(t)$ ". Below this, the equations are written in purple ink:

$$y(t) = x(t) * h(t)$$
$$\Rightarrow Y(\omega) = X(\omega) \cdot H(\omega)$$

$$\Rightarrow H(\omega) = \frac{Y(\omega)}{X(\omega)}$$

A blue arrow points from the $H(\omega)$ term in the second equation to the fraction $\frac{Y(\omega)}{X(\omega)}$ in the third equation. The whiteboard interface includes a toolbar at the top and a status bar at the bottom showing "17 / 66".

Therefore, we have $y(t)$ equals $x(t)$ convolved with $h(t)$. And naturally we also know that the convolution in time domain is multi leads to the multiplication on the corresponding frequency responses.

So, if you take the Fourier when you take the Fourier transform Y of ω that is the multiplication of the corresponding Fourier transforms if $X(\omega)$ times h $H(\omega)$ which implies that you have the response of the impulse function equals $Y(\omega)$ divided by $X(\omega)$ and this is termed as the transfer function frequency response of the system.

(Refer Slide Time: 23:56)

The image shows a whiteboard with handwritten mathematical definitions. At the top, it states $H(\omega) = \frac{Y(\omega)}{X(\omega)}$. Below this, a red double-headed arrow connects $h(t)$ and $H(\omega)$, with the text "Frequency Response of system" written above the arrow. The next line is $H(\omega) = |H(\omega)| e^{j\theta_H}$. Below that, $|H(\omega)|$ is defined as the "Magnitude Response of LTI system" in green. Finally, θ_H is defined as the "Phase Response of LTI system" in purple. The whiteboard interface includes a toolbar at the top and a page number "17" at the bottom.

As you have seen in the context of a Laplace transform also. So, this is termed as the this is termed as the frequency response of the system. I can also characterize the magnitude and phase responses. So, you can write this in polar coordinates as magnitude of H of $j\omega$ of omega times e raised to $j\theta_H$, the magnitude the component the quantity magnitude H omega.

This is termed as the magnitude response of the system magnitude response of the LTI system. And the quantity θ_H this is termed as the phase response; this is termed as the magnitude response of the LTI system; θ_H which is termed as the phase response.

So, we have θ_H of omega which is the transformer which is the frequency response of the LTI system that is nothing, but the Fourier transform the impulse response ok; the magnitude of that magnitude of H of omega is the magnitude response and θ_H that is the phase of H of omega is the phase response.

And remember $h(t)$ the h of omega the frequency response is nothing, but the Fourier transform of the impulse response.

(Refer Slide Time: 25:55)

$\theta_H =$ Phase Response of LTI system
Frequency Response = FT of impulse response

Consider $x(t) = e^{j\omega_0 t}$
Complex Exponential.
 $X(\omega) = 2\pi \delta(\omega - \omega_0)$.

So, frequency response equals Fourier transform is the Fourier transform the impulse response ok. Now in addition consider now the input signal complex exponential; this remember we all know that this is a, this is a complex exponential the Fourier transform of this is X of omega that is the shifted impulse $2\pi \delta(\omega - \omega_0)$ or there is impulse at omega naught scaled by 2π .

(Refer Slide Time: 26:45)

$X(\omega) = 2\pi \delta(\omega - \omega_0)$

$$Y(\omega) = X(\omega) \cdot H(\omega)$$
$$= 2\pi \delta(\omega - \omega_0) H(\omega)$$
$$Y(\omega) = H(\omega_0) 2\pi \delta(\omega - \omega_0)$$

Taking IFT $\Rightarrow y(t) = H(\omega_0) e^{j\omega_0 t}$

And therefore, the response to this input is Y omega equals X omega into H of omega where H is the impulse response.

That is nothing, but $2\pi\delta(\omega - \omega_0)$ into $H(\omega)$ and you can see this is nothing, but because $\delta(\omega - \omega_0)$ is 0 everywhere except where $\omega = \omega_0$. So, this is simply $H(\omega_0) 2\pi\delta(\omega - \omega_0)$.

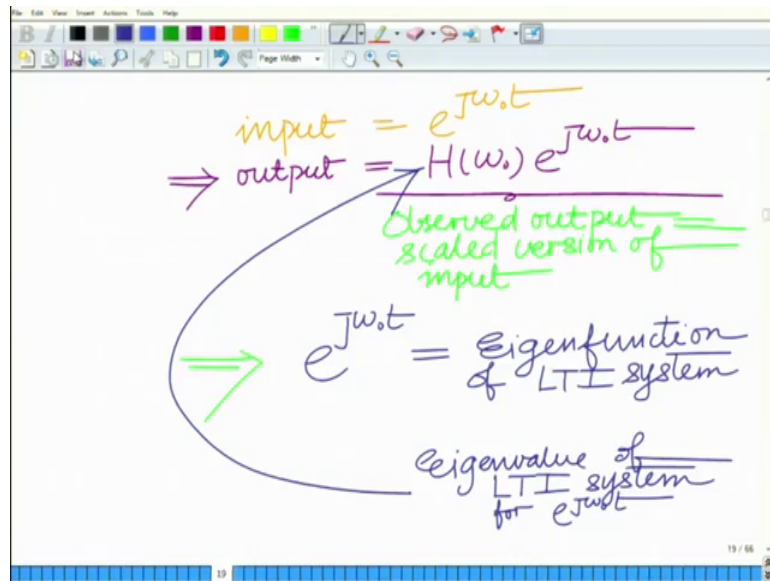

And now if you take the inverse Fourier transform you can see that now taking the IFT you can simply see $Y(\omega)$ is a scaled version of the impulse shifted by ω_0 . So, therefore, this implies $y(t)$ is simply $H(\omega_0)$ times the impulse response of $2\pi\delta(\omega - \omega_0)$ that is $e^{j\omega_0 t}$.

So, what you are seeing is that if you input a complex exponential $e^{j\omega_0 t}$, the output is another complex exponential at the same frequency simply scaled right amplified or attenuated by $H(\omega_0)$ alright. So, what we are seeing is an interesting property where the output is simply a scaled version of the inputs; such a function which when input to your system alright the output is simply a scaled version of the input this is termed as an Eigen function of the system.

And therefore, what you can see is that this complex exponential $e^{j\omega_0 t}$ is an Eigen function of this LTI system of any LTI system for that matter and its corresponding Eigen value is $H(\omega_0)$ that is Eigen; that is the Eigen value corresponding to the complex exponential $e^{j\omega_0 t}$ that is angular frequency with angular frequency ω_0 is $H(\omega_0)$.

That is the impulse response that is the frequency response of the LTI system evaluated at ω_0 .

(Refer Slide Time: 29:01)

So this implies; so, we have input equals $e^{j\omega t}$ and this implies output equals $H(\omega) e^{j\omega t}$, now observe output is a scaled version of input; output equals output is simply a scaled version of the input. This implies $e^{j\omega t}$ this is termed as a Eigen function of the this is termed as an Eigen function of the LTI system.

Because if you have input $x(t)$ the output is simply k times $x(t)$ and this k it is this $H(\omega)$ of ω this is the this is the Eigen value of LTI system for corresponding to $e^{j\omega t}$ corresponding to this Eigen signal $e^{j\omega t}$; corresponding to this Eigen function $e^{j\omega t}$ alright.

So, this basically clarifies that this complex exponentials $e^{j\omega t}$; these are the Eigen functions of the LTI system and the corresponding Eigen values are $H(\omega)$ that is the frequency response evaluated at the frequency ω alright. So, in this module we have seen interesting aspects of the Fourier transform.

We have explored further, we have defined the autocorrelation function of a signal the energy spectral density, we have seen then concept we have understood the concept of the energy spectral density if the Parseval's relation for a continuous aperiodic signal. And we have also seen the Eigen functions of LTI systems alright. So, we will stop here and continue in the subsequent modules.

Thank you very much.
