Lecture - 60

Discrete Fourier Transform-Definition, Inverse DFT, Relation between DFT and DFS, Relation between DFT and DTFT, Properties-Linearity, Time Shifting

Hello, welcome to another module in this massive open online course. So, we are looking at the Fourier analysis of discrete time signals. We have completed our discussion of the discrete time Fourier transform and in this module we will start a different concept that is the discrete Fourier transform ok.

So, we want to start looking at that discrete Fourier transform.

(Refer Slide Time: 00:34)

So, this is the Fourier analysis of discrete time signals and in particular of a very important transform for discrete signals is the discrete Fourier transform, which has revolutionized digital signal processing because there is a very fast way to implement the discrete Fourier transform that is the DFT through the FFT that is the fast Fourier transform routine ok. And that has resulted in a revolution and signal processing cases. One of the most important kinds of transform especially since much of the processing happens in the digital domain. So, it has discrete time signals which are being processed by the aid of the DFT ok.

So, this is used for finite length sequences. As I said it is a very key transform is used heavily in images audio and video processing and for that matter also for communication applications especially wireless communications applications and so on. So, it is used for finite length sequences as I already said correct and the definition is $x[n]$ consider a sequence $x[n]$ and this is a finite length sequence $0 \leq n \leq N-1$ defined only for $0 \leq n \leq N-1$.

(Refer Slide Time: 02:01)

Used for Finite Length Sequences.

$$x(n) \quad 0 \leq n \leq N-1$$

$$X(k) = \sum_{n=0}^{N-1} x(n) e^{-j2\pi kn/N}$$

And $X[k]$ the DFT the k -th DFT coefficient is defined as summation n equal to 0 equal to 0 to $N-1$ $x[n] e^{-j2\pi kn/N}$ that is the expression for the DFT coefficient $X[k]$ and this is defined for this is also a finite length sequence this is defined as for $0 \leq k \leq N-1$. So, the limits of k are $0 \leq k \leq N-1$ ok.

(Refer Slide Time: 02:58)

The image shows a digital whiteboard with the following content:

Sequences

$$x(n) \quad 0 \leq n \leq N-1$$
$$X(k) = \sum_{n=0}^{N-1} x(n) e^{-j2\pi kn/N}$$

$0 \leq k \leq N-1$

$$X(k) = \sum_{n=0}^{N-1} x(n) \frac{e^{-j2\pi kn/N}}{W_N}$$

2 / 70

And this can also be written as follows this can also be written as $X(k)$ equals summation n equal to 0 to N minus 1 $x(n)$ e raised to minus $j 2 \pi$ over N raised to the power of kn .

(Refer Slide Time: 03:53)

The image shows a digital whiteboard with the following content:

$$X(k) = \sum_{n=0}^{N-1} x(n) \frac{e^{-j2\pi kn/N}}{W_N}$$
$$= \sum_{n=0}^{N-1} x(n) W_N^{kn}$$
$$W_N = e^{-j2\pi/N}$$
$$\Rightarrow W_N^{lN} = e^{-2\pi \cdot lN/N} = e^{-2\pi l} = 1$$

2 / 70

Now, if I call this denote this as W_N then I can write this in a very succinct fashion as n equal to 0 to N minus 1 and this now, I can replace by W_N to the power kn ok, where W_N note that W_N equals this is a fundamental quantity e raised to minus $j 2 \pi$ over N . And also note that W_N to the power of any integer k or any integer that is any let us say l times n

equals $e^{-j 2 \pi k m / N}$ which is equal to 1 ok.

So, this is in fact, one of the roots of unity that is what you can see ok. So, W_N is $e^{-j 2 \pi / N}$ and the DFT coefficient $X(k)$ is summation n equal to 0 to $N-1$ $x(n) W_N^{kn}$ ok. So, that gives an expression for the DFT coefficient $X(k)$ ok.

(Refer Slide Time: 05:08)

For IDFT, Note.

$$\sum_{k=0}^{N-1} X(k) e^{j 2 \pi k m / N}$$

$$= \sum_{k=0}^{N-1} \sum_{n=0}^{N-1} x(n) e^{-j 2 \pi k n / N} e^{j 2 \pi k m / N}$$

Now, for the IDFT note that, for IDFT note if you perform summation k equal to 0 to $N-1$ $X(k) e^{j 2 \pi k m / N}$ that is equal to now, substituting the expression for $X(k)$ that is equal to summation k equal to 0 to $N-1$ summation n equal to 0 to $N-1$ $x(n) e^{-j 2 \pi k n / N}$ times $e^{j 2 \pi k m / N}$ over N and now, interchanging the order of summation ok.

(Refer Slide Time: 06:24)

The image shows a whiteboard with a toolbar at the top. The main content is a handwritten mathematical derivation in green ink. It starts with an equation:
$$= \sum_{n=0}^{N-1} x(n) \sum_{k=0}^{N-1} e^{j 2\pi \frac{k}{N} (m-n)}$$
 Below this, there are two lines of text:
$$= 0 \text{ if } m \neq n$$

$$= N \text{ if } m = n.$$
 A horizontal line is drawn below these lines. Below the line, the final result is written:
$$= N x(m).$$
 In the bottom right corner of the whiteboard, the text "4 / 70" is visible.

So, interchanging the order of summation we will have, this will be summation n equal to 0 to N minus 1 x n depends on only on n. So, that comes out summation k equal to 0 to N minus 1 e raised to j 2 pi k over N into m n. And now, you can see this is equal to 0 this is basically the sum of the roots of unity is equal to 0 if m is not equal to n and this is equal to this in fact, equal to n if m equal to n ok. And therefore, this is equal to only the term n corresponding to m survives. So, this is equal to Nx m.

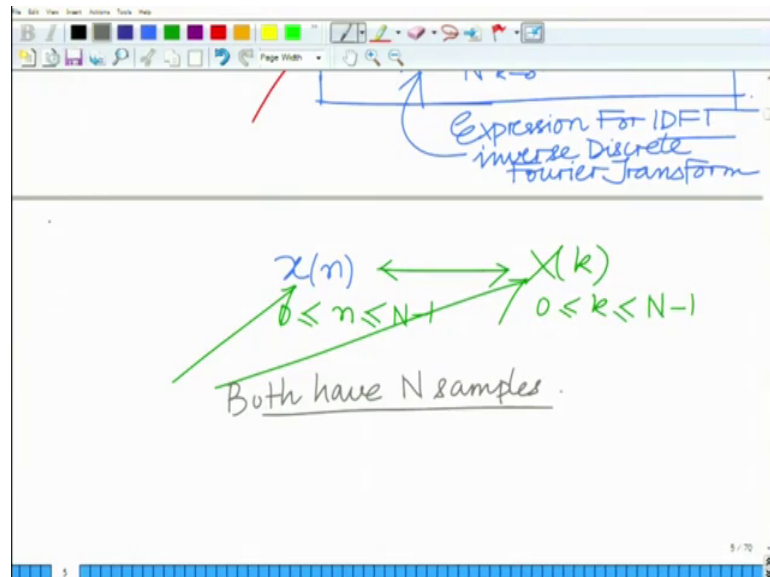

(Refer Slide Time: 07:26)

The image shows a whiteboard with a toolbar at the top. The main content is a handwritten mathematical derivation in red ink. It starts with the equation:
$$= N x(m).$$
 Below this, the equation is written as:
$$N x(m) = \sum_{k=0}^{N-1} x(k) e^{j 2\pi \frac{km}{N}}$$
 Then, it is rearranged to:
$$\Rightarrow x(m) = \frac{1}{N} \sum_{k=0}^{N-1} x(k) e^{j 2\pi \frac{km}{N}}$$
 Finally, the equation is boxed in blue ink:
$$\Rightarrow x(m) = \frac{1}{N} \sum_{k=0}^{N-1} x(k) W_N^{-km}.$$
 In the bottom right corner of the whiteboard, the text "4 / 70" is visible.

So, we have from this manipulation what we have seen is basically that $X(k)$ equals $\sum_{m=0}^{N-1} x(m) e^{-j2\pi km}$, divided by N which implies that $x(m)$ equals $\frac{1}{N} \sum_{k=0}^{N-1} X(k) e^{j2\pi km}$ and in fact, $e^{j2\pi km}$ over N is W_N^{-km} .

So, this implies basically you have $x(m)$ equals $\sum_{k=0}^{N-1} \frac{1}{N} X(k) W_N^{km}$. So, this is the expression for the IDFT inverse discrete Fourier transform. This is your inverse; this is the expression for your inverse discrete Fourier transform ok.

(Refer Slide Time: 08:51)

And this is of course, represented by similar to what we have seen many times before you have $x(n)$ plus $x(n)$ and $X(k)$ for my DFT pair $x(n)$ in the range 0 to capital N minus 1 k also in the range 0 to capital N minus 1 ok, so these for my DFT pair. So, both have N samples ok. So, observe that both have both the original samples and their DFT coefficients are n in number ok, all right.

Now, the next thing we want to look at is we want to look at the relations between these various transforms correct. So, we have seen several transforms we are now, seeing the DFT we have earlier we have seen the Fourier series as well as the discrete time Fourier transform. So, want to look at start by looking at the relation between this DFT and the discrete time Fourier series that is defined for a periodic signal periodic discrete time signal ok.

(Refer Slide Time: 10:39)

The image shows a whiteboard with handwritten text in purple and blue ink. At the top, the title "RELATION BETWEEN DFT & DFS." is written in purple and underlined. Below it, the text "Consider periodic Extension of x(n)." is written in blue. Underneath that, the equation
$$C_k = \frac{1}{N} \sum_{n=0}^{N-1} x(n) e^{j\omega_0 k n}$$
 is written in blue. The whiteboard has a toolbar at the top with various drawing tools and a page number "5 / 70" in the bottom right corner.

So, what we want to look at is basically relation, we want to look at the relation between DFT and DFS ok. So, consider the periodic extension of $x[n]$ and then we have C_k equals $\frac{1}{N}$ summation n equal to 0 to N minus 1 $x[n] e^{j\omega_0 k n}$ ok. So, remember C_k this is the, so we considering a periodic extension of the signal $x[n]$ which is defined for $0 \leq n \leq N-1$.

So, we are extending it periodically which means we are repeating the same sequence $x[n]$ periodically all right. So, this becomes a periodic sequence. And then we can one can consider the DFS of this periodic extension of $x[n]$ and let us C_k denote its DFS coefficient then you can see this implies that $N C_k$ equals you can readily see that $N C_k$ equals $\sum_{n=0}^{N-1} x[n] e^{j\omega_0 k n}$.

(Refer Slide Time: 12:20)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it says $\Omega_0 = \frac{2\pi}{N}$ and $X \text{ DFS}$. Below that, it says "Consider periodic Extension of $x(n)$ ". The equation for the DFS coefficient is $C_k = \frac{1}{N} \sum_{n=0}^{N-1} x(n) e^{-j\Omega_0 kn}$. A horizontal line separates this from the next part, which shows the derivation: $\Rightarrow N C_k = \sum_{n=0}^{N-1} x(n) e^{j\Omega_0 kn}$, which is then simplified to $= \sum_{n=0}^{N-1} x(n) e^{j \frac{2\pi kn}{N}}$. A horizontal line is drawn under the exponent, and the result is labeled $X(k)$.

In fact, we have ω_0 equals 2π by N . So, this becomes summation n equal to 0 to N minus 1 $x(n) e^{j 2\pi kn / N}$ which you can see is nothing, but basically the DFT coefficient $X(k)$.

(Refer Slide Time: 13:09)

The image shows a whiteboard with handwritten notes. It starts with an arrow pointing to a boxed equation: $N C_k = X(k)$. Below the box, there are two annotations: "kth DFS Coeff. of Periodic Extension" with an arrow pointing to $N C_k$, and "kth DFT Coefficient of original signal." with an arrow pointing to $X(k)$.

So, this implies basically that the DFS coefficient, so if C_k denotes the coefficient the k th discrete Fourier series coefficient of the periodic extension then N times C_k equals $X(k)$. And note once again that this is the k th this is the k th DFS coefficient of the, of the

periodic extension and this is the k th DFT coefficient of the original signal, the original time limited signal with capital N samples.

And the other thing that you can see is the relation between the DFT and the DTFT that is a relation between the discrete Fourier transform and the discrete time Fourier transform and that is also fairly simple.

(Refer Slide Time: 14:32)

RELATION BETWEEN DFT
& DTFT:

$$x(n) = \begin{cases} x(n) & 0 \leq n \leq N-1 \\ 0 & \text{otherwise} \end{cases}$$
$$X(e^{j\omega}) = \sum_{n=0}^{N-1} x(n)e^{-j\omega n}$$

So, the next thing that we want to see is the relation between the DFT and relation between the DFT and DTFT ok. And now, consider $x[n]$ equals now, you form a signal such that $x[n]$ equal to that is a consider $x[n]$ for $0 \leq n \leq N-1$ and 0 otherwise ok, and for this signal.

If you look at the DTFT now, the DTFT will naturally be $X(e^{j\omega}) = \sum_{n=0}^{N-1} x[n]e^{-j\omega n}$ because this is 0 outside n equal to 0 to $N-1$. So, this will be n equal to 0 to $N-1$ $x[n]e^{-j\omega n}$.

(Refer Slide Time: 15:52)

$$X(\omega) = \sum_{n=0}^{N-1} x(n) e^{-j\omega n}$$
$$\omega = \frac{2\pi k}{N}$$
$$= \sum_{n=0}^{N-1} x(n) e^{-j \frac{2\pi k n}{N}}$$
$$X(k)$$

\Rightarrow

Now, if you substitute omega equal to 2 pi k over N over N this will become summation n equal to 0 to N minus 1 x n e raised to minus j 2 pi k n over N and which is nothing, but X k. Now, you can see this is nothing, but the DFT coefficient X k.

So, this implies that your X k this implies something very interesting that your X k is nothing, but the DTFT of x omega evaluated at omega equals 2 pi k over N alright.

(Refer Slide Time: 16:24)

$\Rightarrow X(k) = X(\omega) \Big|_{\omega = \frac{2\pi k}{N}}$

PROPERTIES OF DFT :

$$x(n) \quad 0 \leq n \leq N-1$$
$$X(k) \quad 0 \leq k \leq N-1$$

$\Rightarrow x(n-n_0) \equiv x((n-n_0) \bmod N)$

So, that is basically that basically summarizes the DFT the DFT definition the DFT its relation to the discrete Fourier series as well as the DTFT the discrete time Fourier

transform. Let us now, look at some properties of the DFT. So, want to look at the properties of the DFT.

Now, we have $x[n]$ $0 \leq n \leq N-1$ and $X[k]$ $0 \leq k \leq N-1$ n, k are restricted. Now, of course, when we consider $x[n-n_0]$, now it might go outside the range of 0 or $N-1$. So, what one can do is all such things can be restricted to modulo of N in this scenario ok. So, what we mean when we say $x[n-n_0]$ in this case is that the $n-n_0$ has to be interpreted modulo N all right, where N is the total number of samples for instance.

(Refer Slide Time: 18:09)

$$\Rightarrow \tilde{x}(n) = x(n-n_0) \equiv x((n-n_0) \bmod N)$$

$$n=1, N=4, n_0=5$$

$$\tilde{x}(1) = x(1-5) = x(-4)$$

$$= x(-4 \bmod 4)$$

$$= x(0)$$

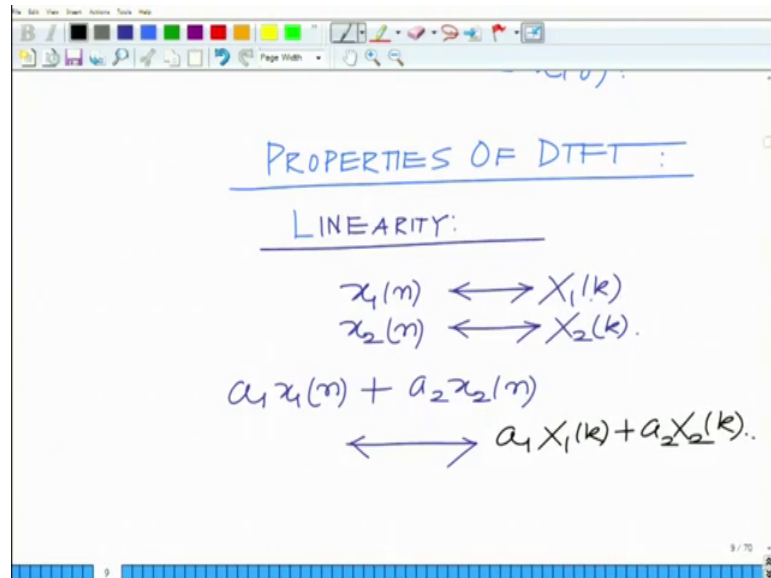

PROPERTIES OF DTFT :

Let us say we have n equal to 1 and capital N equal to 4 . So, we have \tilde{x} of one because let us say we call this as x of n minus n_0 as \tilde{x} ok. So, we have \tilde{x} of 1 , is x of 1 minus 4 I am sorry n equals 5 . Let us say n equals or n_0 equals 5 n equals 4 n_0 equals 5 which is x of $N-1$ minus 5 equals x of minus 4 this is x of minus 4 modulo 4 which is equal to 0 ok.

So, this is basically your x of 0 . So, \tilde{x} of 1 where x is shifted by n_0 equals 5 . So, $\tilde{x}[1]$ that is the first sample of the shifted signal is actually 0 . So, basically you are sort of circularly shifting this alright the shifting is basically modulo, modulo 4 where n of 4 is the N is equal to 4 is the total length of the sequence all right.

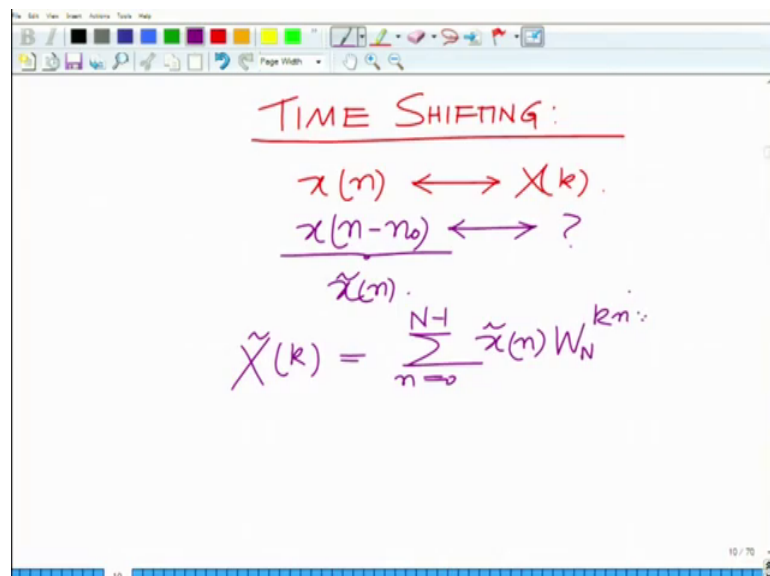

And now, we look at the properties of the DTFT. And the properties of the DTFT are as follows again the standard property we start with linearity which is simple yet fairly powerful and useful properties.

(Refer Slide Time: 19:52)

So, linearity tells us that if $x_1(n)$ has the DFT coefficients $X_1(k)$ and $x_2(n)$ have the DFT coefficients $X_2(k)$ and both have the same length obviously, $0 \leq n \leq N-1$ then $a_1 x_1(n) + a_2 x_2(n)$ has the DTFT $a_1 X_1(k) + a_2 X_2(k)$ all right. So, this is the linearity which we have seen many times before.

(Refer Slide Time: 20:55)

Now, what about time shifting? $x[n]$ has the DTFT $X[k]$ what can we say about $x[n - n_0]$? What can we say about this quantity $x[n - n_0]$? Now, let $n - n_0 \bmod N = m$, all right. So, what we have is so let $n - n_0$. So, we have basically let us denote this by $\tilde{x}[m]$ or let us denote this by $\tilde{x}[n]$. So, $\tilde{X}[k]$ summation n equal to 0 to $N - 1$ $\tilde{x}[n] e^{-jkn}$ or basically you can just write it in terms of W_N , W_N to the power kn .

(Refer Slide Time: 22:31)

The image shows a whiteboard with the following handwritten content:

$$\tilde{X}(k) = \sum_{n=0}^{N-1} \tilde{x}(m) W_N^{km}$$

$$n - n_0 \bmod N = m$$

$$\Rightarrow n - n_0 = LN + m$$

$$\Rightarrow n = n_0 + LN + m$$

The whiteboard also features a toolbar at the top and a status bar at the bottom indicating slide 10 of 70.

Now, let $n - n_0 \bmod N = m$ or $n - n_0 \bmod N = m$ this implies n equals $n_0 + m$. So, with this implies $n - n_0 \bmod N = m$ is basically or $n - n_0$ is basically sum is basically some constant L times N plus m ok. So, this is some multiple of this is some $n - n_0$ is some multiple of $n_0 + m$ ok. So, which implies n equals $n_0 + LN + m$.

(Refer Slide Time: 23:32)

$$\begin{aligned} \tilde{X}(k) &= \sum_{n=0}^{N-1} x(n-n_0) W_N^{kn} \\ &= \sum_{m=0}^{N-1} x(m) W_N^{k(n_0+LN+m)} \\ &= \sum_{m=0}^{N-1} x(m) W_N^{kn_0} \cdot \frac{W_N^{kLN}}{W_N^{km}} \end{aligned}$$

So, we have $\tilde{X}(k)$, again $\tilde{X}(k)$ now, if you write $\tilde{X}(k)$, if you write $\tilde{X}(k)$ this will be summation n equal to 0 to $N-1$ $x(n-n_0)$ or basically x of $n-n_0$ W_N to the power of kn .

Now, remember $x(n-n_0)$ has to be interpreted as $n-n_0$ modulo N which is m . So, this will be summation again m also goes from 0 to $N-1$ $x(m) W_N$ to the power of $k(n_0+LN+m)$ and this is equal to this is equal to summation m equal to 0 to $N-1$ $x(m) W_N$ to the power of kn_0 into W_N to the power of kLN which is 1 into W_N to the power of km ok. And now, W_N to the power of kn_0 comes outside because it does not depend on m . So, that is W_N to the power of kn_0 summation m equal to 0 to $N-1$ $x(m) W_N$ to the power of km which is basically this quantity is basically $X(k)$.

(Refer Slide Time: 25:07)

The image shows a handwritten derivation on a whiteboard. The top part shows the equation
$$= W_N^{kn_0} \sum_{m=0}^{N-1} x(m) W_N^{km}$$
 with a horizontal line underneath the sum, and $X(k)$ written below the line. The bottom part shows the simplified equation
$$= W_N^{kn_0} X(k)$$
. The whiteboard has a toolbar at the top and a page number '12 / 70' at the bottom right.

So, this is W time W N times W N times k n naught into x which is similar to basically the modulation property or basically the time shift in time leads to modulation in the frequency domain time shift leads to modulation in the frequency. So, that is basically W N . So, what you have is basically x of n minus n naught has the DFT which is W N to the power of k n naught which is X k ok, all right.

(Refer Slide Time: 26:00)

The image shows a handwritten derivation on a whiteboard. The top part shows the equation
$$= W_N^{kn_0} \sum_{m=0}^{N-1} x(m) W_N^{km}$$
 with a horizontal line underneath the sum, and $X(k)$ written below the line. The middle part shows the simplified equation
$$= W_N^{kn_0} X(k)$$
. The bottom part shows a boxed equation
$$x(m-n_0) \longleftrightarrow W_N^{kn_0} X(k)$$
. The whiteboard has a toolbar at the top and a page number '12 / 70' at the bottom right.

So, that basically covers the time shift property, alright. So, in this module we have introduced the DFT looked at its definitions some of its properties. So, we will stop here and continue in the subsequent modules.

Thank you very much.
