Lecture - 58

Example Problem: Orthogonal Matching Pursuit (OMP) algorithm

Hello, welcome to another module in this massive open online course. So, we are looking at schemes or techniques compare compresses using, and we have seen that orthogonal matching pursuit for compressive sensing alright. Or 2 basically for sparse signal recovery, that is to estimate a sparse signal \bar{x} all right. So, we have seen this algorithm in the previous module; let us now look at an example to understand this better.

(Refer Slide Time: 00:41)

OMP: EXAMPLE:

$$\bar{y} = \Phi \bar{x}$$

$$\begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \\ x_6 \end{bmatrix}$$

\bar{y} 4×1 Φ 4×6 \bar{x} 6×1

$M = 4$ # Equations.
 $N = 6$ # unknowns.
 $M < N \Rightarrow$ # Equations

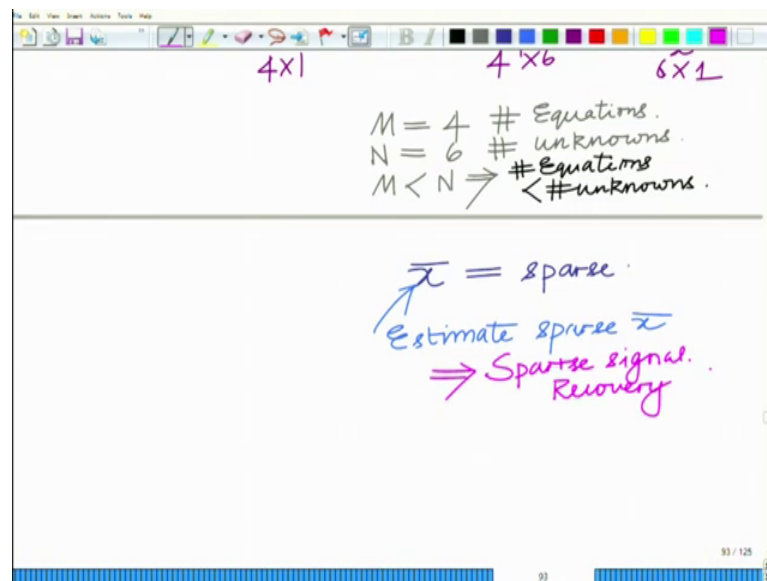

So, what we want to look at is the orthogonal matching pursuit. We have already seen the orthogonal matching pursuit. So now, what we want to see is an example a simple example of paper and pen kind of example for the orthogonal matching pursuit. And let us consider the following example we have \bar{y} equals $\Phi \bar{x}$ we have to estimate the vector \bar{x} .

So, let us consider the example that is given as follows. The vector \bar{y} is 0 2 3 and 5 and the matrix Φ is the following this is 1 0 1, 0 0 1, this is 0 triple 1 0 0 1. This is the third

row 1 0 0 1 1 0 and the 4th row is 0 1 0 0 1 1 times the vector \bar{x} which is basically x_1, x_2, x_3, x_4, x_5 .

So, this is your \bar{y} , this is your dictionary of sensing matrix ϕ this is your matrix \bar{x} , and so, the various parameters of this are as follows. This \bar{y} is a 4 cross on vector, the matrix ϕ is 4 cross 6 and \bar{x} is 6 cross 1.

(Refer Slide Time: 02:41)

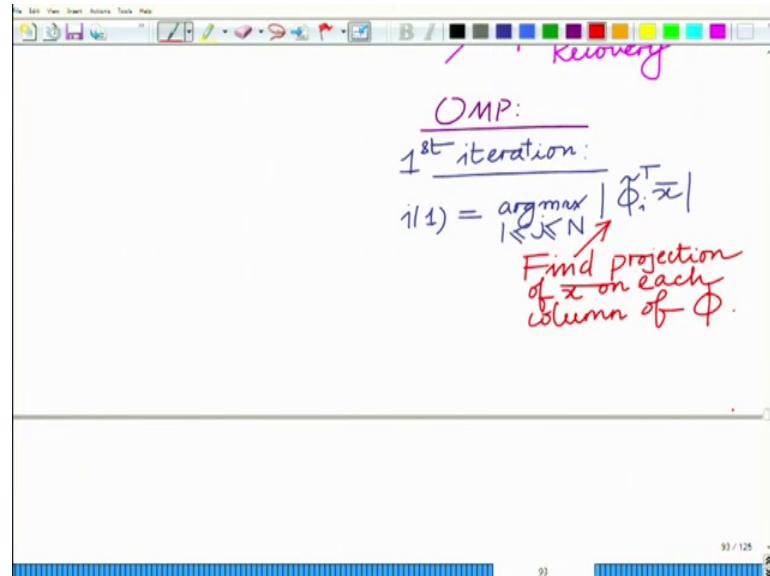

And therefore, in this problem we have M equals 4 which is basically the number of equations. And N equals 6 which is the number of unknowns. And we can see M less than N , which implies number of equations less than number of unknowns. And therefore, to estimate \bar{x} or basically to recover \bar{x} alright, where is \bar{x} .

Remember you cannot use conventional linear algebra, will basically because in linear algebra you need at least number of equations at least or number of equations equal to the number of unknowns or the number of equations at least equal to the number of unknowns to uniquely determine the unknown vector \bar{x} . And therefore, one as to enforce some other condition on \bar{x} to uniquely recover it and the condition that we have seen so far; that is to enforce sparsity.

That is, to determine a sparse vector \bar{x} that satisfies this system of equations alright. So, or that fits this model. So, we assume that \bar{x} is sparse, and then we want to

estimate this sparse vector. And this is basically what is termed as sparse signal recovery. The system does sparse signal recovery.

(Refer Slide Time: 04:41)

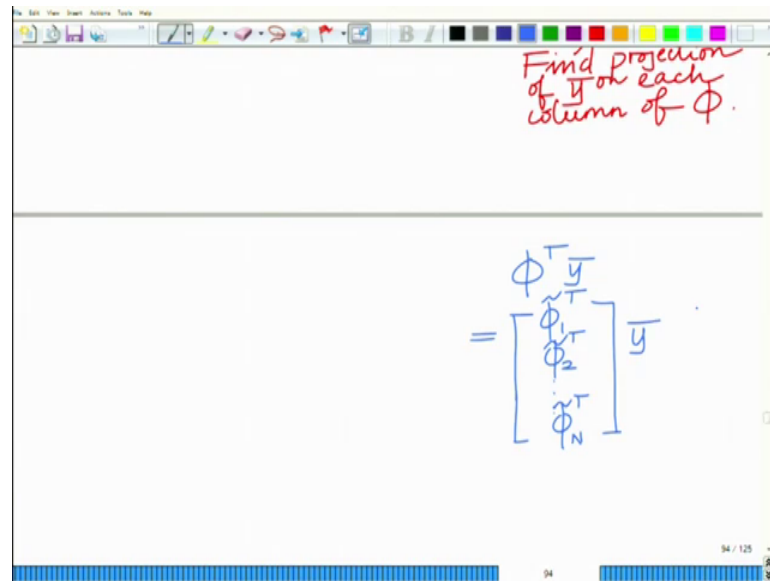

And the algorithm we have seen OMP for sparse signal recovery that proceeds as follows.

First find the projection so, we can see these are the columns, now remember when you talk this \bar{y} , these are the columns for instance this is $\tilde{\phi}_1$, this is $\tilde{\phi}_2$ and so on and so forth, this is $\tilde{\phi}_N$ or in this case N equal to 6. So, this is $\tilde{\phi}_6$. So, what we will do is, we will find so, OMP remember the first iteration.

The first iteration, you find the projection of \bar{x} on each column of the matrix Φ which is on each $\tilde{\phi}_i$ and choose the column which yield the largest projection, all right. So, remember you have $i = \underset{1 \leq j \leq N}{\operatorname{argmax}} |\tilde{\phi}_j^T \bar{x}|$. In fact, one less than equal to j less than equal to N magnitude $\tilde{\phi}_i^T \bar{x}$. And remember is and what we can and this we can do as a following thing.

So, basically what we are doing is finding projection of \bar{y} on each column of Φ . This can be done as follows, what we are going to do or a fine projection of \bar{y} , I am sorry fine projection of \bar{y} on each column of Φ . And what way this can be done as follows.

(Refer Slide Time: 07:03)

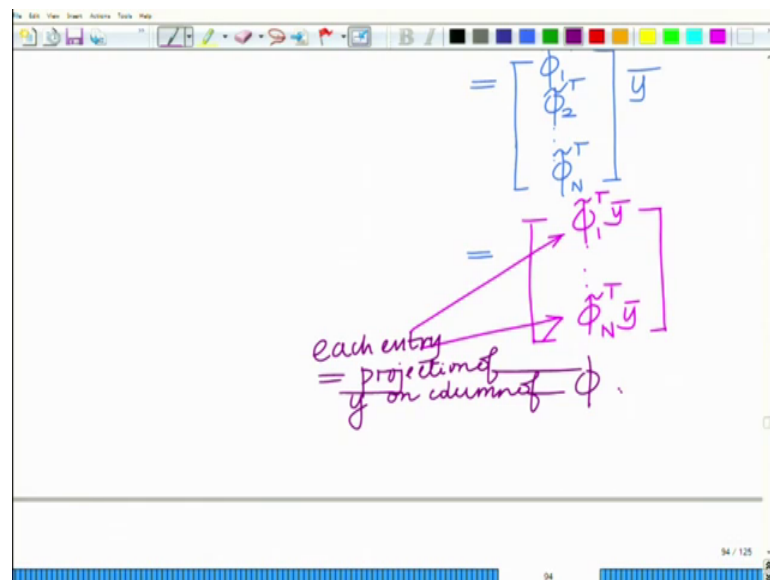

Find projection of \bar{y} on each column of Φ .

$$\Phi^T \bar{y} = \begin{bmatrix} \tilde{\phi}_1^T \\ \tilde{\phi}_2^T \\ \vdots \\ \tilde{\phi}_N^T \end{bmatrix} \bar{y}$$

So, what we are going to do is, we are simply going to perform $\Phi^T \bar{y}$. What that gives us is that gives us basically the inner product of each $\tilde{\phi}_1^T$ $\tilde{\phi}_2^T$ $\tilde{\phi}_N^T$ \bar{y} .

(Refer Slide Time: 07:33)

$$= \begin{bmatrix} \tilde{\phi}_1^T \\ \tilde{\phi}_2^T \\ \vdots \\ \tilde{\phi}_N^T \end{bmatrix} \bar{y}$$
$$= \begin{bmatrix} \tilde{\phi}_1^T \bar{y} \\ \vdots \\ \tilde{\phi}_N^T \bar{y} \end{bmatrix}$$

each entry = projection of \bar{y} on column of Φ .

Which is basically nothing but if you look at this, this is basically $\tilde{\phi}_1^T$ up to $\tilde{\phi}_N^T$ into \bar{y} .

So, each of these entries corresponds to. So, each entry equals projection of \bar{y} on column of Φ . Now the other thing that you must have observed is if you look at these

rows, you can see that these rows are random 0's and 1. So, these are noise like waveforms ok. So, that is other important thing. So, rows of phi a random 0 columns. So, these are noiseless remember that is an important criteria remember, we cannot take time domain or special domain measurements. But you have to take the projections of x bar on random noise like waveform alright.

So, each measurement is basically each observation is a projection of y for y bar on this noise like waveform.

(Refer Slide Time: 09:11)

$$\Phi^T = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 1 & 1 \\ 1 & 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \\ 7 \end{bmatrix}$$

$$= \begin{bmatrix} 3 \\ 7 \\ 5 \\ 8 \\ 5 \end{bmatrix}$$

maximum = 5th entry = $\Phi_5^T \cdot y$

So now let us find phi transpose y bar phi transpose y bar remember, phi transpose is this matrix, in which the rows become columns and the columns become rows. So, first row will be 1 0 1 0 0 1 0 1 1 1 0 0 0 1 1 0 0 0 1 1 1 0 0 1, and you take the projection of y bar.

So, that is 0 2 3 5 and if you compute this, if you evaluate this, you will get the vector 3 7 2 5 8 5. Remember, each of this entries is the projection for instance 3, this is equal to phi 1 tilde transpose y bar 7 equals phi 2 tilde transpose y bar and so on. And if you see the maximum occurs equals 5th entry or 5th component, which is equal to phi 5 tilde transpose y bar. Therefore, the maximum projection of y bar, y bar has a maximum projection along column phi, along column phi; that is, corresponds to phi tilde phi.

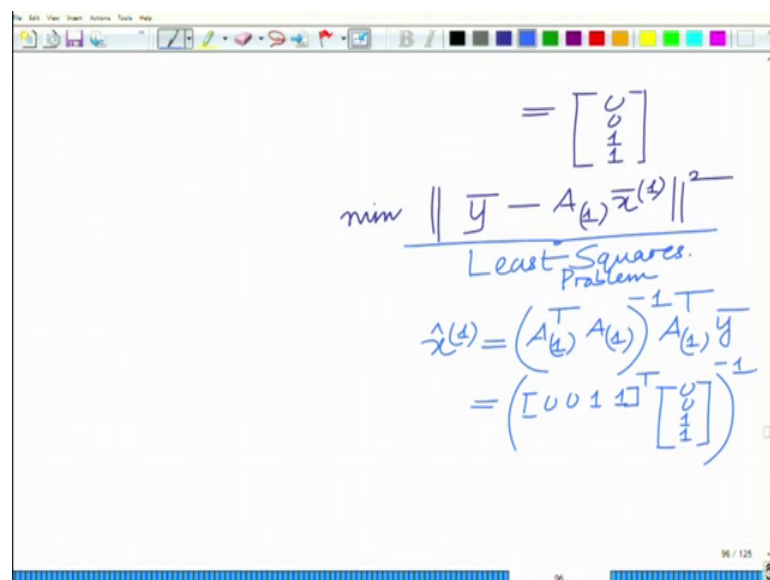

(Refer Slide Time: 10:53)

Therefore, now we form the basis matrix using this column $\tilde{\Phi}_5$. Or in other words what we are saying is this quantity $i(4)$; that is, index of the column which has the maximum projection that is $\tilde{\Phi}_5$.

So, this is $\tilde{\Phi}_5$ which is basically $\tilde{\Phi}_5$, that is your basis matrix.

(Refer Slide Time: 11:43)

Which is basically that is nothing but this you take the 5th column of the matrix Φ . And that will be 5th column of matrix, 5th column of matrix \bar{y} that will be 0 0 1 1. So, this is

the 5th column of, and now you solve the least squares problem. $\bar{y} - A_1 \bar{x}$, remember this is the first iteration.

So, you solve the least squares problem. And once you solve this least squares problem, remember the solution to this is $\hat{x}_1 = (A_1^T A_1)^{-1} A_1^T \bar{y}$. which is A_1^T , remember $A_1 = \begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix}$. So, this is $\begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix}^T$, this is very simple, simply row vector transpose.

(Refer Slide Time: 13:14)

The image shows a whiteboard with the following handwritten content:

$$\hat{x} = \frac{1}{2} \begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$$

$$= \frac{1}{2} \begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$$

$$\hat{x}^{(1)} = \frac{1}{2} \times 8 = 4.$$

Estimate in 1st iteration

The column vector $\begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix}$ inverse of this times $A_1^T \begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix}$ times $\begin{bmatrix} 0 & 2 & 3 & 5 \end{bmatrix}$, ok. And this will be half because $A_1^T A_1$, this is row vector times of column vector will be 2. So, inverse of that is half times $\begin{bmatrix} 0 & 0 & 1 & 1 \end{bmatrix}$ times $\begin{bmatrix} 0 & 2 & 3 & 5 \end{bmatrix}$. So, this will be half into 8 equal to 4.

So, this is basically your \hat{x}_1 , ok. So, that is basically your estimate of the sparse vector in the first. Remember this \hat{x}_1 corresponds to the index of the column that is chosen in the first iteration that is column number 5. So, your sparse vector so, this entry corresponds to the 5th column or the 5th entry of the vector \bar{x} . Now what we will do is, we find the residue after the first iteration ok. So now, find the residue so, this is the estimate and now what we will do is, we will find the residue for the first iteration.

(Refer Slide Time: 14:45)

The image shows a handwritten derivation on a whiteboard. At the top, the equation $\hat{x} = \frac{1}{2} \times 0 = 0$ is written in green. Below it, the text "Estimate in 1st iteration" is written in blue. The word "Residue:" is underlined in purple. The derivation follows:
$$r(1) = \bar{y} - A(1) \hat{x}^{(1)}$$
$$= \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix} - \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix} \times 0$$
$$= \begin{bmatrix} 0 \\ 2 \\ -1 \\ 1 \end{bmatrix}$$
 A blue arrow points from the text "Residue in 1st iteration" to the resulting vector. The whiteboard interface includes a toolbar at the top and a status bar at the bottom showing "97 / 125".

And the residue is r_1 or rather \bar{r}_1 , \bar{y} minus $A_1 \hat{x}_1$; which is $\begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$ minus $A_1 \hat{x}_1$ is simply the column $\begin{bmatrix} 0 \\ 0 \end{bmatrix}$ into 4.

So, this will be basically $\begin{bmatrix} 0 \\ 2 \\ -1 \\ 1 \end{bmatrix}$, this is the residue in first iteration, ok. There is a residue after the first iteration. And this is in fact, what we carry over to the second iteration. Remember, subsequently find the projections of the columns of Φ on this residue choose the one that has the maximum repeat the process least square solution, alright find the residue repeat the process. Now let us go to the second iteration.

(Refer Slide Time: 16:24)

2nd iteration:

Find projection of $\bar{r}(1)$ i.e. residue from 1st iteration, on each column of Φ .

$$\Phi^T \bar{r}(1) = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ -1 \\ 1 \\ 1 \end{bmatrix}$$

So, let us look at now second iteration. In second iteration, we find projection of r bar 1, that is residue from first iteration on each column of phi. And therefore, again similarly what we will do we will do? Phi transpose r bar 1; which will basically give the projection of the residue on each column of phi ok. So, this will be 1 0 1 0 0 1 0 1 1 1 0 0 0 1 1 0 0 0 1 1 1 0 0 1, on the residue, 0 2 minus 1 1.

(Refer Slide Time: 18:03)

$$\Phi^T \bar{r}(1) = \begin{bmatrix} 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 0 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ -1 \\ 1 \\ 1 \end{bmatrix}$$

$$= \begin{bmatrix} -1 \\ 3 \\ 2 \\ 1 \\ 0 \\ 1 \end{bmatrix} \quad \Phi_2^T \bar{r}(1)$$

maximum corresponds to 2nd column $i(2) = 2$

$$A_{(2)} = \begin{bmatrix} \Phi_2 & \Phi_5 \end{bmatrix}$$

Now, you take this projection, you evaluate this you will see that this comes down to minus 1 3 2 1 0 1. And what you observe that now the maximum is 3, maximum

corresponds to second column. This is basically $\tilde{\Phi}_2^T r$. So, the maximum entry corresponds to the projection of the residue r on the second column that is $\tilde{\Phi}_2^T r$. Therefore, you now choose the second column. You make the augmented matrix. So, the augmented matrix becomes, previously we have $\tilde{\Phi}_2$ now we are identify.

Now remember you can also write it as $\tilde{\Phi}_5$ comma $\tilde{\Phi}_2$ it does not matter. It does not as long as you are clear that this is the order and therefore, corresponding the entries of \tilde{x} will \hat{x} will correspond to these 2 columns. So, basically your matrix in fact, I should write it like this. These are simply the columns of the matrix ok. So, you have matrix you are picking the columns $\tilde{\Phi}_5$ $\tilde{\Phi}_2$ $\tilde{\Phi}_5$.

(Refer Slide Time: 19:37)

The image shows a whiteboard with handwritten mathematical expressions. At the top, there is a red note: "Consider the 2nd column" with a bracket under the number 2. Below this, the augmented basis matrix is defined as:

$$A_{(2)} = \begin{bmatrix} \tilde{\Phi}_2 & \tilde{\Phi}_5 \end{bmatrix}$$

An arrow points from the text "Augmented Basis matrix" to the matrix $A_{(2)}$. Below this, the matrix is shown in its numerical form:

$$= \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{bmatrix}$$

At the bottom, the least squares problem is formulated as:

$$\min. \| \bar{y} - A_{(2)} \bar{x}^{(2)} \|^2$$

And these will be so, this is basically what it says is $i=2$, that is the index picked up in the second iteration is basically 2, ok. And the columns corresponding columns are 0 1 0 1 and 0 0 1 1. And now you again solve the least squares problem. Now you have the estimate \hat{x} ; which is basically you solve the least squares problem $\bar{y} - A_{(2)} \bar{x}^{(2)}$.

Second iteration $\bar{x}^{(2)}$ whole square it is a least squares problem. Remember this is your, you can call this as the augmented basis matrix.

(Refer Slide Time: 20:40)

$$= \begin{bmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{bmatrix}$$

$$\min. \| \bar{y} - A_{(2)} \bar{x}^{(2)} \|^2$$

$$\hat{x}^{(2)} = (A_{(2)}^T A_{(2)})^{-1} A_{(2)}^T \bar{y}$$

$$= \left(\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 1 & 1 \end{bmatrix} \right)^{-1}$$

$$\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$$

And once you solve this least squares problem what you get is, $\hat{x}^{(2)}$ equals $A_{(2)}^T A_{(2)}^{-1} A_{(2)}^T \bar{y}$; which is basically if you look at $A_{(2)}^T A_{(2)}$, that is $\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$, $A_{(2)}^T A_{(2)}$ into inverse into $A_{(2)}^T \bar{y}$.

(Refer Slide Time: 21:41)

$$\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix} \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$$

$$= \left(\begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} \right)^{-1} \times \begin{bmatrix} 7 \\ 8 \end{bmatrix}$$

$$= \frac{1}{3} \begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 7 \\ 8 \end{bmatrix}$$

$$\hat{x}^{(2)} = \frac{1}{3} \begin{bmatrix} 6 \\ 9 \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

Once again $\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$ into \bar{y} ; which is $\begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$ which basically equals this is 2, this is $\begin{bmatrix} 1 & 1 \\ 2 & 2 \end{bmatrix}$ inverse of this matrix times $\begin{bmatrix} 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{bmatrix}$ times \bar{y} $\begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix}$, that will be basically $\begin{bmatrix} 7 \\ 8 \end{bmatrix}$. And inverse of this 2 cross 2 matrix is very simple. You interchange the

diagonal elements which are the same. Negative of diagonal elements, and you divide by the determinant 1 by 4 minus 1 which is 3 times 7 8. So, this is 1 by 3 times 16 minus 7 is 9. I am sorry, 14 minus 8 is 6 16 minus 7 is 9, and this will given now give us 2 3 very simple.

And this is basically this is nothing but your \hat{x}^2 . Estimate of \hat{x}^2 estimate in the second iteration.

(Refer Slide Time: 22:55)

The image shows a whiteboard with the following handwritten mathematical steps:

$$= \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}^{-1} \times \begin{bmatrix} 7 \\ 8 \end{bmatrix}$$

$$= \frac{1}{3} \begin{bmatrix} 2 & -1 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} 7 \\ 8 \end{bmatrix}$$

$$\hat{x}^{(2)} = \frac{1}{3} \begin{bmatrix} 6 \\ 9 \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

Estimate in 2nd iteration

$$r(2) = \bar{y} - A(2) \hat{x}^{(2)}$$

The whiteboard also features a toolbar at the top with various drawing tools and a status bar at the bottom showing '100 / 125'.

This is estimate in the second iteration. And now of course, we again need to find the residue. That is $r(2) = \bar{y} - A(2) \hat{x}^2$.

(Refer Slide Time: 23:28)

The image shows a whiteboard with the following handwritten mathematical expressions:

$$= \begin{bmatrix} 0 \\ 2 \\ 3 \\ 5 \end{bmatrix} - \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

$$r^{(2)} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \leftarrow \text{residue} = 0$$

$$\hat{x}^{(2)} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

$$\bar{y} = A_{(2)} \hat{x}^{(2)}$$

$$= \begin{bmatrix} \tilde{\phi}_2 & \tilde{\phi}_5 \end{bmatrix} \hat{x}^{(2)}$$

This will be $0 \ 2 \ 3 \ 5$ minus A_2 ; which is $0 \ 1 \ 0 \ 1 \ 0 \ 0 \ 1 \ 1 \ 2 \ 3$. And you can calculate this, and what you will see is this residue is exactly 0. Residue equal to 0, this is your r bar 2 r bar 2. So, the residue equals 0 which basically means that you are exactly able to exactly approximate y bar in the second iteration, which means you are using the basis matrix in the second iteration. That is comprising which comprise of the columns $\tilde{\phi}_2$ and $\tilde{\phi}_5$.

Therefore, your $\hat{x}^{(2)}$ or the second iteration and what we have is \bar{y} equals A_2 , it is basically as 2 columns, $\tilde{\phi}_2$ $\tilde{\phi}_5$ into $x^{(2)}$.

(Refer Slide Time: 25:08)

$$\bar{y} = A^{(2)} x$$

$$= \begin{bmatrix} \tilde{\phi}_2 & \tilde{\phi}_5 \end{bmatrix} \hat{x}^{(2)}$$

Exactly approximates \bar{y}

$$\hat{x}^{(2)} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

$\tilde{\phi}_2 = 2^{\text{nd}} \text{ column of } \phi$

$\tilde{\phi}_5 = 5^{\text{th}} \text{ column of } \phi$

So, this is able exactly approximates \bar{y} . And therefore, residue 0 no further iterations are needed. So, which means if you look at \hat{x} of 2; which is equal to 2 comma 3, 2 corresponds to remember, each correspond 2 corresponds to $\tilde{\phi}_2$; which is basically second column of ϕ . And 3 corresponds to $\tilde{\phi}_5$ equals 5th column of the matrix ϕ .

(Refer Slide Time: 26:04)

$$\hat{x}^{(2)} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

$\tilde{\phi}_2 = 2^{\text{nd}} \text{ column of } \phi$

$\tilde{\phi}_5 = 5^{\text{th}} \text{ column of } \phi$

Estimate of sparse vector \bar{x}

$$\bar{x} = \begin{bmatrix} 0 \\ 2 \\ 0 \\ 3 \\ 0 \end{bmatrix}$$

Rest of entries 0

2nd entry $\tilde{\phi}_2$

5th entry $\tilde{\phi}_5$

And therefore, now you can reconstruct the sparse vector \bar{x} as follows, only the second entry will be 2, and 5th entry will be 3 and the rest of the entries are 0.

So, this is second entry corresponding to ϕ_2 , this is 5th entry corresponding to ϕ_5 , and rest of the entries, rest of the entries are 0. Rest of the entries are 0, and therefore, this is your estimate of the sparse vector \bar{x} . And of course, as we said this is a simple example it is simply a paper and pen example something that you can do on the back of an envelope kind of a calculation.

But of course, problems in practice this is just for the purpose of illustration, with problems in practice are frequently more complex, and they will be quite involved for instance the size of the dictionary matrix Φ can be of the size, 500 cross let us say 10,000. Remember, the characteristic of Φ it will always have many much fewer rows than columns, because the columns represent the unknowns, the rows represent the observations all right.

But you can use this OMP algorithms scale it up and use it for similar scenarios. And as I have already said OMP the interesting thing about OMP is that it is a very simple algorithm, all you are doing at each stage is finding the projection of \bar{y} .

And it is finding the position of \bar{y} or the residue on each column of Φ ; choosing the one that has a maximum projection all right. Computing the least squares estimate that gives you the estimate \hat{x} corresponding to the sparse vector in that iteration, remove the current estimate the best approximation to \bar{y} all right. Form the residue and then continue in the subsequent iterations right.

So, this is OMP algorithm this example clearly illustrates the process hopefully it clarifies. Some of your doubts or, some of how do I put it points which are points which earlier lacking clarity, because the algorithm was theoretical in nature. So, this algorithm sort of explicitly illustrates the OMP the working of OMP through an exam, all right. So, let us stop here, and continue in the subsequent modules.

Thank you very much.
