Lecture – 65
Example problem on Strong Duality

Hello welcome to another module in this massive open online course. So, we are looking at duality and we have seen the concept of strong duality that is for any optimization problem, standard written in the standard form, one can come up with an equivalent dual optimization problem which is convex.

You can solve that and to obtain the optimal point d^* and if strong duality holds then, now usually d^* is less than equal to P^* where P^* is the optimal value of the original primal problem, but when strong duality holds which is usually true for a convex optimization problem we have d^* equals P^* ok. And now let us understand that through an example alright.

(Refer Slide Time: 00:54)

So, let us look at an example to understand the same, this explore duality, in particular let us look at the minimum norm problem that we have seen so far. So, as an example let us look at the minimum norm problem and the problem is the following minimize norm of a vector \bar{x} . So, this is your objective, subject to the constraint $A \bar{x} = \bar{b}$ ok.

And you can see these are only equality constraints, there is no inequality constraint ok. So, this is only an equality there is only an equality constraint to approach this problem let us form.

(Refer Slide Time: 01:50)

problem

min. $\|\bar{x}\| = \sqrt{\bar{x}^T \bar{x}}$ $m \times n$ Equality constraint

s.t. $A \bar{x} = \bar{b}$

$\begin{bmatrix} a_1^T \\ a_2^T \\ \vdots \\ a_m^T \end{bmatrix} \bar{x} = \bar{b}$ ← m Equality constraints

$\bar{\nu} = \begin{bmatrix} \nu_1 \\ \nu_2 \\ \vdots \\ \nu_m \end{bmatrix}$ $\nu_i = \text{Lagrange multiplier for } a_i^T \bar{x} = b_i$

Lagrangian $L(\bar{x}, \bar{\nu})$

Now, look at this has although this might seem like a single constraint, if A is an m cross n matrix ok, which means it has m rows a 2 bar transpose a m bar transpose correct.

It is an m cross n matrix this is a m bar transpose and x bar equals b bar so, in reality there are m constraints ok. So, there are m equality constraints one for each row of the matrix A. And therefore, the Lagrange multipliers for each equality constraint, you need to have one Lagrange multiplier for each equality constraint so, you have a vector nu 1 nu 2 nu m where nu m is or nu i equals Lagrange multiplier for the constraint, a bar transpose x bar equals bi ok.

So, this is what the ith constraint alright. So, you have m constraint m constraints 1 corresponding to each row of the matrix a the corresponding Lagrange multiplier is nu i alright and therefore, you have the vector, nu bar which comprises of the Lagrange multipliers nu 1 nu 2 up to nu r.

(Refer Slide Time: 03:30)

Lagrangian

$$L(\bar{x}, \bar{\lambda}) = \bar{x}^T \bar{x} + \bar{\lambda}^T (A\bar{x} - \bar{b})$$

$$\min_{\bar{x}} L(\bar{x}, \bar{\lambda})$$

$$\frac{\partial}{\partial \bar{x}} L(\bar{x}, \bar{\lambda}) = 2\bar{x} + (\bar{\lambda}^T A)^T = 0$$

$$\Rightarrow 2\bar{x} + A^T \bar{\lambda} = 0$$

$$\Rightarrow \boxed{\bar{x} = -\frac{1}{2} A^T \bar{\lambda}}$$

Now, the Lagrangian can be formulated as follows, in the Lagrangian that is a L of x bar and only nu bar is no lambda bar, because there is no there are no inequality constraints.

So, this is basically the objective function now, instead of minimizing norm x 1 can also minimize norm x bar square which is basically equal to x bar transpose x bar ok. And therefore, this you can write the objective function was x bar transpose x bar plus nu bar transpose ok. So, basically each Lagrange multiplier is multiplying the corresponding law A x bar minus b bar ok.

So, this nu bar transpose is basically your row vector nu 1 nu 2 up to so, you have each Lagrange multiplier multiplied in a corresponding row. And then you are taking the sum that is what this nu bar transpose is doing. Now, we find the minimum all right in the first type find minimum of the Lagrange multiplier of the Lagrangian of the Lagrangian with respect to x bar.

So, which means we have to compute the partial derivative with respect to x bar and set it equal to 0 ok. So, compute the partial derivative with respect to x bar set it equal to 0, we know how to differentiate this vector, this function of a vector x bar transpose x bar derivative with respect to x bar is twice x bar plus nu bar transpose A into x bar.

So, this is basically your x bar transpose x bar plus nu bar transpose A x bar minus nu bar transpose b bar. Now of course, the derivative of nu bar transpose b bar with respect x

bar is 0, derivative of nu bar transpose that is c transpose x bar with respect to x bar is c bar, which is basically this is your c bar transpose. So, derivative is c bar which means it is the transpose that is nu bar transpose A, this is c transpose. So, transpose of this plus or minus derivative of nu bar transpose b bar with respect to x bar is 0 ok.

And this we are setting equal to 0 to find the optimal point, this implies $2x$ bar plus A transpose nu bar equal to 0 which implies that x bar equals minus half A transpose nu bar ok. So, x bar equals minus half A transpose nu ok. So, that is basically the x bar for which the minimum is achieved for the Lagrangian corresponding to the original optimization problem ok. Now, to get the dual optimization problem is substitute this.

(Refer Slide Time: 06:38)

$$g(\bar{v}) = \bar{x}^T \bar{x} + \bar{v}^T (A\bar{x} - \bar{b})$$

substitute
 $\bar{x} = -\frac{1}{2}A^T\bar{v}$

$$= \left(-\frac{1}{2}A^T\bar{v}\right)^T \left(-\frac{1}{2}A^T\bar{v}\right) + \bar{v}^T \left(A\left(-\frac{1}{2}A^T\bar{v}\right) - \bar{b}\right)$$

So, now, what we do is g of nu is basically nothing, but you substitute, this that is the minimum value of the Lagrangian ok, for that you substitute the x bar so, that is so in this remember this is your original optimization problem x bar transpose x bar plus nu bar transpose A x bar minus b bar in this what we do is we substitute x bar equals minus half A transpose nu bar.

So, that will give you g of nu bar equals well minus half A transpose nu bar transpose minus half A transpose nu bar plus nu bar transpose A minus half A transpose nu bar minus b bar. So, wherever there is x bar i am substituting minus half A transpose nu bar.

(Refer Slide Time: 08:06)

The image shows a whiteboard with the following handwritten derivation:

$$\begin{aligned}
 &= \left(-\frac{1}{2}A^T\bar{v}\right)\left(-\frac{1}{2}A^T\bar{v}\right) \\
 &\quad + \bar{v}^T\left(A\left(-\frac{1}{2}A^T\bar{v}\right) - \bar{b}\right) \\
 &= \frac{1}{4}\bar{v}^TAA^T\bar{v} - \frac{1}{2}\bar{v}^TAA^T\bar{v} \\
 g(\bar{v}) &= -\frac{1}{4}\bar{v}^TAA^T\bar{v} - \bar{v}^T\bar{b}
 \end{aligned}$$

And this is equal to 1 by 4 nu bar transpose A A transpose nu bar minus half nu bar transpose A A transpose nu bar minus nu bar transpose b bar. And now if you simplify it what you will get is basically minus 1 by 4 nu bar transpose A, A transpose nu bar minus nu bar transpose b bar. So, this is your Lagrangian function.

(Refer Slide Time: 08:59)

The image shows a whiteboard with the following handwritten notes and diagram:

- The equation $g(\bar{v}) = -\frac{1}{4}\bar{v}^TAA^T\bar{v} - \bar{v}^T\bar{b}$ is circled in green and labeled "concave".
- The entire equation is enclosed in a blue box labeled "Lagrange Dual Function".
- Below the equation, the term $-\bar{v}^TAA^T\bar{v}$ is written, with "PSD" written below it. This term is underlined, and "convex" is written below the underline, and "concave" is written below that.
- To the right, the inequality $g(\bar{v}) \leq P^*$ is written in a box.
- An arrow points from P^* to the text " $P^* = \text{optimal value of Primal problem}$ ".

So, let me just write this again when minimizing the Lagrangian, what you are obtaining is a Lagrange dual function, which is minus 1 by 4 nu bar transpose A A transpose nu bar minus nu bar transpose b bar ok. So, this is your Lagrange dual function ok. And this will

always give a lower bound, now remember this will always give a lower bound. So, g of ν bar is always less than or equal to P^* for any value of ν bar, we will have that g of ν bar that is the value of this Lagrange dual function alright. Remember, there are no inequality constraints so, there is no Lagrange multiplier or there is no Lagrange multiplier vector λ bar.

So, this g of ν bar is a Lagrange dual function alright in fact, this is g of ν bar so, which is g of ν bar is always less than equal to P^* , where P^* equals optimal value of the original or primal problem ok. So, this is always going to be a lower bound. Now, what is the best lower bound and look at this there is also a concave function, because if you look at this you can see here, this is minus of the form minus ν bar $A^T A$ transpose ν bar. So, this is a PSD matrix positive semi definite so, ν bar transpose $A^T A$ transpose ν bar is convex minus ν bar transpose $A^T A$ transpose ν bar equals is concave ok.

So, this is a concave so, you can see that this is clearly and this is of course, concave function ν bar transpose b bar which is basically a linear function so, the base which is also concave so, basically it is a concave. So, it is a g of ν bar so, if you look at this is a concave function ok. And this is a concave function this is always a lower bound for P^* .

(Refer Slide Time: 11:36)

The image shows a whiteboard with handwritten mathematical expressions. At the top, it says "Best Lower bound" followed by an equals sign and "max. $g_d(\bar{\nu})$ ". Below that, it shows an equals sign and a fraction: the numerator is $-\frac{1}{4} \bar{\nu}^T A A^T \bar{\nu}$ and the denominator is $-\bar{\nu}^T \bar{b}$. Below this, it shows the derivative of $g_d(\bar{\nu})$ with respect to $\bar{\nu}$ is equal to $-\frac{1}{4} 2 A A^T \bar{\nu} - \bar{b}$, with an equals sign and a zero below the expression. A blue arrow points downwards from the derivative equation. The whiteboard has a toolbar at the top and a status bar at the bottom showing "42 / 95".

$$\begin{aligned} \text{Best Lower bound} &= \max. g_d(\bar{\nu}) \\ &= \max. \frac{-\frac{1}{4} \bar{\nu}^T A A^T \bar{\nu}}{-\bar{\nu}^T \bar{b}} \\ \frac{dg_d(\bar{\nu})}{d\bar{\nu}} &= -\frac{1}{4} 2 A A^T \bar{\nu} - \bar{b} = 0 \\ &\Rightarrow \end{aligned}$$

Now, one can ask what is the best lower bound the best lower bound is given by, the best lower bound is given by the maximum value. Once again note that there is no there are no inequality constraints therefore, we do not have the constraint that lambda bar has to be component wise greater than equal to 0 all right. So, I simply have to maximize this Lagrangian dual function which is g_d of $\bar{\nu}$.

This is maximized minus 1 by 4 $\bar{\nu}$ transpose $A A$ transpose $\bar{\nu}$ minus $\bar{\nu}$ transpose \bar{b} . And now if your different to maximize this, if you differentiate this with respect to $\bar{\nu}$ what you get is well this is minus 1 by 4 and $\bar{\nu}$ transpose $A A$ transpose $\bar{\nu}$. So, the derivative of that is twice $A A$ transpose $\bar{\nu}$ minus $\bar{\nu}$ transpose \bar{b} derivative of that with respect to $\bar{\nu}$ is simply \bar{b} .

(Refer Slide Time: 12:59)

The whiteboard shows the following handwritten text:

$$\Rightarrow \bar{\nu} = -2(AA^T)^{-1}b$$
$$\bar{\nu} = -2(AA^T)^{-1}b$$

Below this, it says:

$$d^* = \text{optimal value of Dual Problem}$$
$$=$$

And now you equate it to 0 which implies the optimal value of nu bar for which this Lagrangian, before which the dual function is maximized is minus 2 A A transpose inverse into b bar. So, we have nu bar that is minus 2 A A transpose inverse into b bar ok.

That is the value of nu bar for which the Lagrange dual function is maximized. Now, therefore, the optimal value d star this is the optimal value of the dual problem, simply substitute nu bar in the dual problem, that is basically this nu bar value of nu bar in the dual problem.

(Refer Slide Time: 13:58)

The whiteboard shows the following handwritten text:

$$d^* = \text{optimal value of Dual Problem}$$
$$= -\frac{1}{4} \bar{\nu}^T (AA^T) \bar{\nu} - \bar{\nu}^T b$$

Substitute $\bar{\nu} = -2(AA^T)^{-1}b$

$$= -\frac{1}{4} \left(-2(AA^T)^{-1}b \right)^T AA^T \left(-2(AA^T)^{-1}b \right)$$

That is minus 1 by 4 nu bar transpose A A transpose nu bar minus nu bar transpose b bar so, what you do here is you substitute nu bar equals minus 2 A A transpose inverse into b bar. So, if you substitute that what you have is it is a little cumbersome, but you can write this so, nu bar transpose which is minus 2 A A transpose inverse b bar transpose into A A transpose into nu bar.

(Refer Slide Time: 14:58)

The whiteboard shows the following derivation:

$$-\frac{1}{4} \left(-2(AA^T)^{-1} \bar{b} \right)^T \bar{b}$$

$$= -\bar{b}^T (AA^T)^{-1} \bar{b} + 2 \cdot \bar{b}^T (AA^T)^{-1} \bar{b}$$

$$d^* = \bar{b}^T (AA^T)^{-1} \bar{b}$$

So, that is minus 2 A A transpose inverse into b bar, minus nu bar transpose b bar so that is minus 2 A A transpose inverse b bar transpose of that that is nu bar transpose b bar.

And if you simplify this what you will get is minus b bar transpose A A transpose inverse into b bar plus twice b bar transpose, you can simplify this A A transpose inverse into b bar and that is basically b bar transpose A A transpose inverse into b bar and that is your d star, that is the optimal value of the dual problem ok. So, this is d star.

(Refer Slide Time: 15:54)

Handwritten mathematical derivation on a whiteboard:

$$= -b^T (AA^T)^{-1} b + 2 \cdot b^T (AA^T)^{-1} b$$

$$d^* = b^T (AA^T)^{-1} b$$

Optimal value of Dual Problem.

Primal Problem.

$$\min. \|\bar{x}\|^2 = \bar{x}^T \bar{x}$$

$$\text{s.t. } A\bar{x} = b$$

This is the optimal value of the; this is the optimal value of the dual problem ok. So, this is d^* which is of course, always less than or equal to P^* . Now, let us see what is P^* that is optimal value of the primal problem we already know that, because you solve the minimum norm problem alright. So, this is the optimal value of the dual problem. Now, let us go back to the primal problem, remember the primal problem is minimize norm \bar{x} square, that is $\bar{x}^T \bar{x}$ subject to the constraint $A \bar{x} = b$.

(Refer Slide Time: 16:52)

Handwritten mathematical derivation on a whiteboard:

$$\bar{x} = A^T (AA^T)^{-1} b$$

$$P^* = \frac{\bar{x}^T \bar{x}}{\substack{\text{Substitute} \\ \bar{x} = A^T (AA^T)^{-1} b}}$$

$$= (A^T (AA^T)^{-1} b)^T \times (A^T (AA^T)^{-1} b)$$

$$=$$

And we know that the optimal solution for this is \bar{x} equals this we know from the previous modules that optimal solution for the minimum norm problem is $A^T A^{-1} \bar{b}$.

And now P^* which is optimal value of the dual problem that is basically your $\bar{x}^T \bar{b}$. And here you substitute $\bar{x} = A^T A^{-1} \bar{b}$ into $\bar{x}^T \bar{b}$. And that gives you what does that give you that use $\bar{b}^T A^{-1} A^T \bar{b}$, which you can simplify and if you simplify it no wonder what you are going to observe is this is $\bar{b}^T A^{-1} A^T \bar{b}$.

(Refer Slide Time: 18:05)

The image shows a whiteboard with handwritten mathematical derivations. At the top, the equation $P^* = \bar{b}^T (A^T A^{-1}) \bar{b}$ is written. Below this, the expression is simplified to $P^* = d^*$, which is enclosed in a purple rectangular box. An arrow points from this boxed equation to the text "strong Duality holds!" which is underlined in purple. The whiteboard also shows a standard software toolbar at the top and a status bar at the bottom with the number "46".

This is P^* and from what you can observe above this also exactly equal $\bar{b}^T A^{-1} A^T \bar{b}$ so, this is in fact exactly equal to d^* so, we have $P^* = d^*$ and therefore, strong duality holds and in fact, one can immediately say that, there is a value of the dual problem for because the dual optimization.

Because the dual objective is always less than or equal to the primal, dual objective always is a lower bound for the primal objective function. So, the dual objective in the primal object were coinciding that implies that, that point is the maximum value of the dual objective function dual optimization problem and is also the corresponding point is the optimal value of the primal objective.

And in this case P star we have P star equal to d star and therefore, strong duality. And in fact, the optimization problem is convex and that is what we have set for convex optimization problem, typically strong duality holds. So, P star equal to d star this implies that strong, strong duality holds and that is what we have already seen that strong duality holds for this optimization problem ok. So, this is one of the simplest and most elegant optimization problems that is the (Refer Time: 19:51). Let us look at another interesting problem and that problem is as follows.

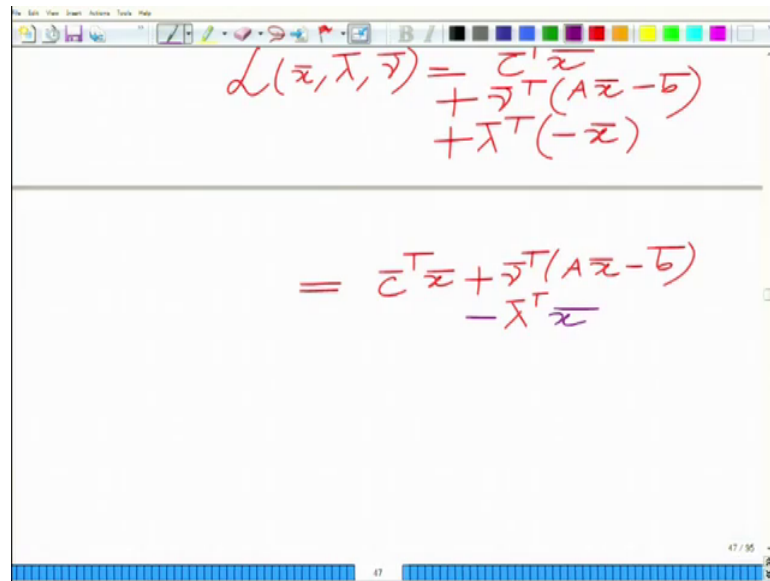

(Refer Slide Time: 20:02)

Linear Program:

$$\begin{aligned} \min. & \quad \bar{c}^T \bar{x} \\ \text{s.t.} & \quad A \bar{x} = \bar{b} \\ & \quad \bar{x} \geq 0 \Rightarrow -\bar{x} \leq 0 \end{aligned}$$

Let us look at another interesting problem and that is a linear program let us see what duality has to tell us. Now, for a linear programs look at the standard linear program or one of the versions, that is minimize the linear objective \bar{c} transpose \bar{x} subject to $A \bar{x}$ equal to \bar{b} these are the equality constraints, and then let us say that \bar{x} is component wise greater than equal to 0 each component of the vector \bar{x} is greater than equal to 0. You can write this as a standard form convex optimization problem, by saying each component of minus \bar{x} is less than or equal to 0 ok.

(Refer Slide Time: 20:46)

$$\begin{aligned} \mathcal{L}(\bar{x}, \bar{\lambda}, \bar{\nu}) &= \bar{c}^T \bar{x} \\ &\quad + \bar{\nu}^T (A\bar{x} - \bar{b}) \\ &\quad + \bar{\lambda}^T (-\bar{x}) \\ &= \bar{c}^T \bar{x} + \bar{\nu}^T (A\bar{x} - \bar{b}) \\ &\quad - \bar{\lambda}^T \bar{x} \end{aligned}$$

Now, the Lagrangian of this can be formulated as \bar{x} , now you have both inequality and equality constraints. So, the Lagrangian will be objective function $\bar{c}^T \bar{x}$ plus $\bar{\nu}^T (A\bar{x} - \bar{b})$ plus $\bar{\lambda}^T (-\bar{x})$. I am sorry, that is your same as before. $\bar{\nu}$ is the vector comprising of the Lagrange multiplier for the equality constraint plus $\bar{\lambda}$ is the vector comprising of the Lagrange multiplier for each inequality constraint. So, the Lagrangian is $\bar{c}^T \bar{x} + \bar{\nu}^T (A\bar{x} - \bar{b}) + \bar{\lambda}^T (-\bar{x})$.

Each in fact, the size of the vector $\bar{\lambda}$ is equal to \bar{x} , because you have one Lagrange multiplier for each component of \bar{x} that is less than or greater than equal to 0. So, we can directly write this as $\bar{c}^T \bar{x} + \bar{\nu}^T (A\bar{x} - \bar{b}) - \bar{\lambda}^T \bar{x}$. Now, we have to take the minimum of the Lagrangian right and typically for that we differentiate it with respect to the vector \bar{x} , but since this is a linear this is an affine function we will follow a slightly different approach.

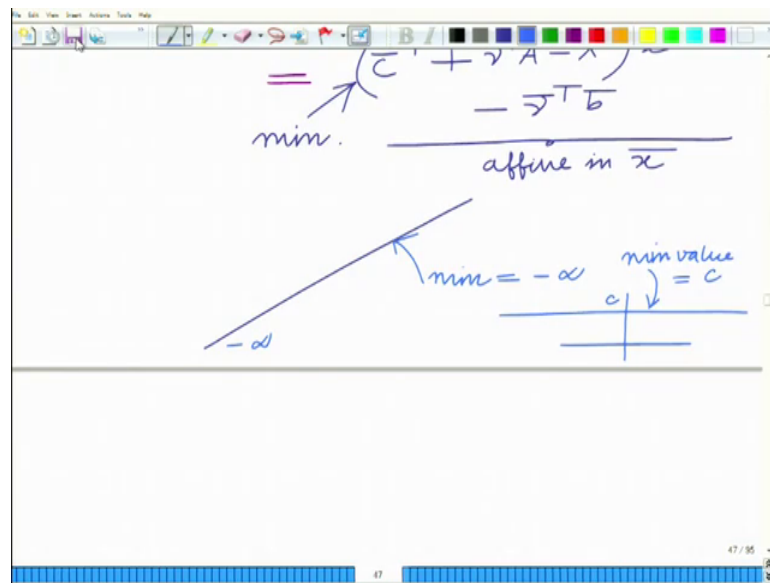

(Refer Slide Time: 22:14)

The image shows a whiteboard with handwritten mathematical equations. The first equation is
$$= \bar{c}^T \bar{x} + \bar{\nu}^T (A\bar{x} - \bar{b}) - \bar{\lambda}^T \bar{x}$$
. The second equation is
$$= \underbrace{(\bar{c}^T + \bar{\nu}^T A - \bar{\lambda}^T)}_{\text{min.}} \bar{x} - \bar{\nu}^T \bar{b}$$
. Below the second equation, the text "affine in \bar{x} " is written. The whiteboard has a toolbar at the top and a status bar at the bottom showing "47 / 95".

And that is as follows and interestingly, if you separate the terms, if you write this as the terms corresponding to \bar{x} plus $\bar{\nu}^T A \bar{x}$ minus $\bar{\lambda}^T \bar{x}$ minus and the constant term.

You can see this is affine in \bar{x} which is basically it is a, you can see this is the equation of this is the equation of basically a hyperplane, this is the equation of a hyperplane correct. Now, if you see what is now what we have to do is now we have to minimize this ok. And what you will observe is, you will observe something interesting. Now, this is an affine function it is like a line correct.

(Refer Slide Time: 23:08)

So, let us look at this line if this line has a slope, then the minimum value of this will always be equal to minus infinity, because one of the ends will always be minus infinity. Only if the line is parallel, then the minimum value that is the line is a constant ok.

And then the minimum value equal to c that is a constant ok. So, this is very interesting, because it is affine if the vector multiplying \bar{x} is non zero, then the minimum value is always going to be minus infinity right in that case it has a slope. If that is 0 that is a vector multiplying \bar{x} is equal to 0, then the minimum value is the constant which in this case is minus $\bar{b}^T \bar{b}$ ok.

(Refer Slide Time: 24:02)

The image shows a whiteboard with handwritten mathematical expressions. At the top, it says $\min_x \mathcal{L}(\bar{x}, \bar{\lambda}, \bar{\nu})$. Below that, the dual function is defined as $g_d(\bar{\lambda}, \bar{\nu}) = \begin{cases} -\infty, & \text{if } \bar{c}^T + \bar{\nu}^T A - \bar{\lambda}^T \neq 0 \\ -\bar{\nu}^T \bar{b}, & \text{if } \bar{c}^T + \bar{\nu}^T A - \bar{\lambda}^T = 0. \end{cases}$ The second case is circled in blue. The whiteboard has a toolbar at the top and a status bar at the bottom showing '48 / 95'.

So, with that observation we have the minimum of the Lagrangian, this is L if \bar{c} transpose plus $\bar{\nu}$ transpose A minus $\bar{\lambda}$ transpose is not equal to 0, the minimum is minus infinity, if \bar{c} transpose plus $\bar{\nu}$ transpose A minus $\bar{\lambda}$ transpose equal to 0, that is this vector which is multiplying \bar{x} . This vector is not equal to 0 then the minimum is minus infinity, on the other hand if that vector is 0 then the minimum is simply the constant that is minus $\bar{\nu}$ transpose \bar{b} .

Now, of course, minus infinity is always a lower bound for any optimization problem all right. So, this is your Lagrange dual function minus infinity is always a lower bound correct, it is very uninteresting the interesting lower bound occurs for this that is minus $\bar{\nu}$ transpose \bar{b} . And the best lower bound is a where ever is when you maximize this with respect to $\bar{\nu}$ $\bar{\lambda}$.

(Refer Slide Time: 25:38)

The image shows a whiteboard with handwritten mathematical equations. At the top, there is a toolbar with various drawing tools. The main content is as follows:

$$\begin{aligned} \max. & \quad -\bar{\nu}^T \bar{b} \\ \text{s.t.} & \quad \bar{c}^T + \bar{\nu}^T A - \bar{\lambda}^T = 0 \\ & \quad \bar{\lambda} \geq 0 \\ & \Rightarrow \bar{c}^T + \bar{\nu}^T A = \bar{\lambda}^T \geq 0 \end{aligned}$$

$$\Rightarrow \bar{c}^T + \bar{\nu}^T A \geq 0$$
$$\max. \quad -\bar{\nu}^T \bar{b}$$

At the bottom right corner of the whiteboard, there is a small text "49/95" and a small icon.

So, the dual optimization problem can be equivalently written as maximize minus nu bar transpose b bar subject to the constraint, c bar transpose plus nu r transpose A minus lambda bar equal to 0. And of course, we always have this constraint as well that is the Lagrange multipliers corresponding to the inequality constraint, or component wise greater than equal to 0 that is each Lagrange multiplier lambda is greater than equal to 0.

Now, you can see that c bar transpose plus nu bar transpose A minus lambda bar transpose equal to 0. So, if you will now we can simplify this further. So, this implies, what does this imply? This implies that c bar transpose plus nu bar transpose A equal to lambda bar transpose which is component wise greater than equal to 0. So, this implies that c bar transpose plus nu bar transpose A is component wise greater than equal to 0 ok.

(Refer Slide Time: 26:53)

$$\begin{aligned} \max. & \quad -\bar{\nu}^T \bar{b} \\ \text{s.t.} & \quad \bar{c}^T + \bar{\nu}^T A \geq 0 \end{aligned}$$

$= \bar{\lambda}^T$

$$\begin{aligned} \max. & \quad -\bar{\nu}^T \bar{b} \\ \text{s.t.} & \quad A^T \bar{\nu} + \bar{c} \geq 0 \end{aligned}$$

Linear Program. Dual Optimization problem

And therefore, now you can simplify this optimization problem as simply this, maximize minus nu bar transpose b bar subject to the constraint that c bar transpose plus nu bar transpose A, component wise greater than equal to 0 that is and whatever is c bar transpose plus nu bar transpose A, that is equal to now this quantity is equal to itself equal to you can set this quantity. Once you obtain this quantity you can set this quantity equal to lambda bar transpose alright.

And in fact, I am just going to take the transpose of this. So, I am just going to take I can also write this as this is a row vector, I can write this as minus nu bar transpose b bar subject to the constraint A transpose nu bar plus c bar, this is component wise greater than equal to 0. And this is the equivalent dual optimization problem yes, this is the dual optimization problem.

And since this is a convex optimization problem, that is the original problem is a linear program the dual optimization problem you can also see is a linear program, that is the dual of a linear program is a linear program is a convex optimization problem. Therefore, strong duality holds P star optimum value of the original dual optimal; original optimization problem, you will see is equal to the d star which is optimal value of the equivalent dual optimization all right. So, we will stop here and continue in the subsequent modules.

Thank you very much.
