Examples on Duality: Dual Norm, Dual of Linear Program (LP)

Hello, welcome to another module, in this massive open online course. Let us continue looking at examples and in this module let us looking, let us start looking at examples pertaining to duality ok. So, we want to start looking at examples related to concepts of Duality ok, and what we have seen is the following.

(Refer Slide Time: 00:25)

Let us start with the first example that is something interesting pertains to this concept of a dual norm. And now, the dual norm for instance if you have a vector \bar{x} and this is the l norm alright, for instance, l can be 2, that is the l_2 norm or one l_1 norm and so on. Now, the dual norm of this is denoted by norm z l^* , which is defined as the maximum of \bar{z} transpose \bar{u} or all elements, such that norm of \bar{u} l is less than or equal to norm of \bar{u} l is less than or equal to 1, ok.

(Refer Slide Time: 02:12)

The image shows a whiteboard with handwritten mathematical notes. At the top, it says "Dual Norm". Below that, it defines the dual norm as $\|z\|_{2^*} = \max \{ \bar{z}^T \bar{u} \mid \|\bar{u}\|_2 \leq 1 \}$. An example is given for $l_1 = 2$ and l_2 Norm. Below this, an optimization problem is written: $\max \bar{z}^T \bar{u}$ subject to $\|\bar{u}\|_2 \leq 1$, labeled as an "Opt problem". A Cauchy-Schwarz inequality is written below: $\bar{z}^T \bar{u} \leq \|z\| \|\bar{u}\|$.

So, this is basically the dual norm. So, this is the l_1 , this is the original norm and this is basically the dual norm, this is the dual norm and now, for instance, let us look at some examples of course, this is simply a definition. Let us look at some examples to understand this. Let us consider l_2 , that is we are talking about the l_2 norm. We are talking about the l_2 norm, therefore, what is the dual norm?

That is the dual norm of the l_2 norm is maximum over all \bar{z} transpose \bar{u} , such that the l_2 norm, l_2 norm of \bar{u} is less than equal to 1 for instance. Now, let us look at this, let us look at, so this is basically, now if you look at this, you have this maximum of \bar{z} transpose \bar{u} . Over all such vectors norm \bar{u} is less than equal to 1. This is the pertinent optimization problem and of course, you can see, this is convex in nature because, this is a, linear objective convex constraint ok, and now this is easy to solve.

In fact, we know that, magnitude of \bar{z} transpose \bar{u} is less than or equal to, in fact, \bar{z} transpose \bar{u} itself is less than or equal to norm of \bar{z} into norm of \bar{u} . So, we know for two vectors \bar{z} and \bar{u} , \bar{z} transpose \bar{u} is less than equal to norm of \bar{z} times norm of \bar{u} . All right, the dot product is less than equal to the product of the norms. This follows from the Cauchy Schwarz Inequality this is from the.

(Refer Slide Time: 04:16)

$$\frac{z^T \bar{u}}{\|z\| \|\bar{u}\|} \leq 1$$
 Cauchy Schwarz inequality

$$\Rightarrow z^T \bar{u} \leq \|z\| \|\bar{u}\| \leq \|z\|$$

$$\Rightarrow z^T \bar{u} \leq \|z\|$$
 maximum when \bar{u} is aligned with z
 $\|\bar{u}\| = 1$
 $\Rightarrow \bar{u} = \frac{z}{\|z\|}$

Now, we know that this norm \bar{u} is less than or equal to 1, which basically implies z bar transpose \bar{u} is less than equal to norm z bar times. Norm \bar{u} , which is in turn less than or equal to norm z bar because, norm \bar{u} is less than equal to 1, which implies that basically, z bar transpose \bar{u} less than or equal to norm z bar and when does the maximum error, we know the maximum occurs when \bar{u} is aligned in the direction when maximum for \bar{u} is aligned with z bar, \bar{u} is aligned with z bar and norm \bar{u} equals 1, which implies \bar{u} equals z bar divided by norm z bar.

(Refer Slide Time: 05:35)

$$\Rightarrow z^T \bar{u} \leq \|z\|$$
 maximum when \bar{u} is aligned with z
 $\|\bar{u}\| = 1$
 $\Rightarrow \bar{u} = \frac{z}{\|z\|}$

The maximum

$$= \frac{z^T z}{\|z\|}$$

$$= \|z\|_2$$
 Default $= \|\cdot\|_2$

So, the maximum occurs, when \bar{u} is \bar{z} divided by $\|\bar{z}\|$ and the maximum is $\bar{z}^T \frac{\bar{z}}{\|\bar{z}\|}$. The maximum equals well \bar{z}^T substitute instead of, \bar{u} substitute \bar{z} divided by $\|\bar{z}\|$. So, this is $\bar{z}^T \bar{z}$ square by $\|\bar{z}\|$. So, its $\bar{z}^T \bar{z}$ square by $\|\bar{z}\|$. It is a $\bar{z}^T \bar{z}$ of course, all these are 2 norm because, as I mentioned when there is no norm mentioned by default 2 norm ok.

(Refer Slide Time: 06:19)

The maximum

$$= \frac{\bar{z}^T \bar{z}}{\|\bar{z}\|}$$

$$= \|\bar{z}\|_2$$
 Default $= \|\cdot\|_2$

$$\|\bar{z}\|_{2^*} = \|\bar{z}\|_2$$

 dual Norm of l_2 norm is l_2 Norm itself

And therefore, you observe something interesting, what you observe is that the dual norm of the 2 norm equals the 2 norm itself ok. So, this is very interesting dual norm of the l_2 norm is the dual norm of the l_2 norm is the l_2 norm itself ok.

(Refer Slide Time: 07:01)

The image shows a whiteboard with handwritten mathematical notes. At the top, it asks "Dual Norm = ?". Below that, it defines the l-infinity norm of a vector \bar{u} as the maximum of its components: $\|\bar{u}\|_\infty = \max\{|u_1|, |u_2|, \dots, |u_m|\} = \max\{|u_i|\}$. Then, it defines the dual norm of \bar{z} as the maximum value of the dot product $\bar{z}^T \bar{u}$ over all vectors \bar{u} such that $\|\bar{u}\|_\infty \leq 1$. A green arrow points from the constraint $\|\bar{u}\|_\infty \leq 1$ to the equivalent expression $\max\{|u_i|\} \leq 1$.

$$\text{Dual Norm} = ?$$
$$\|\bar{u}\|_\infty = \max\{|u_1|, |u_2|, \dots, |u_m|\}$$
$$= \max\{|u_i|\}$$
$$\|\bar{z}\|_{\infty^*} = \max\left\{\bar{z}^T \bar{u} \mid \|\bar{u}\|_\infty \leq 1\right\}$$
$$\Rightarrow \max\{|u_i|\} \leq 1$$

Now, let us look at another interesting one, do you want to consider (Refer Time: 07:01) the l infinity norm? We want to ask the question, what is the dual norm of the l infinity norm? Now remember l infinity norm, that is norm of l norm of u bar l infinity, infinity is simply the maximum of magnitude u 1 magnitude u 2 magnitude u n or simply the, maximum of the magnitudes of all components of this.

Now, what is the dual norm of the infinity norm, that is norm z bar of infinity dual norm is the maximum, that is your maximum of z bar transpose u r such that the infinity norm of u bar is less than or equal to 1, now what is z bar transpose u bar, now norm infinity norm of u bar less than equal to 1. This implies maximum value of magnitude u i is less than equal to 1.

(Refer Slide Time: 08:34)

The whiteboard shows the following derivation:

$$\|z\|_{\infty} = \max\{|z_i|\}$$

$$\|z\|_{\infty} = \max\left\{\frac{z^T u}{\|u\|_{\infty}} \mid \|u\|_{\infty} \leq 1\right\}$$

where $\Rightarrow \max\{|u_i|\} \leq 1$

$$z^T u = \sum_{i=1}^n z_i u_i$$

$$\leq \sum_{i=1}^n |z_i u_i|$$

Now, assume z and u both to be n dimensional vectors. Now, what is this? This is simply equal to summation i equal to 1 to n z_i times u_i , and now if you look at this. Now, therefore, now this is your z bar transpose u bar, which is simply the dot product between two. It is a summation of component y , that summation of component y s product, that is summation of i equal to 1 to n z_i times u_i , when n is the dimension of each vector. Now, this is less than or equal to; obviously, the summation i equal to 1 to n magnitude z_i magnitude z_i times u_i , which is equal to summation i equal to 1 to n magnitude z_i magnitude u_i .

(Refer Slide Time: 09:29)

The whiteboard shows the following derivation:

$$z^T u = \sum_{i=1}^n z_i u_i$$

where $\Rightarrow \max\{|u_i|\} \leq 1$
 $\Rightarrow |u_i| \leq 1$
 $i=1, 2, \dots, n$

$$\leq \sum_{i=1}^n |z_i u_i|$$

$$= \sum_{i=1}^n |z_i| |u_i| \leq 1$$

$$\leq \sum_{i=1}^n |z_i|$$

Now, we know magnitude u_i less than each magnitude, u_i is less than equal to 1. Now, look at this maximum value of magnitude u_i less than or equal to 1, this implies magnitude u_i less than equal to 1 for all i , i equals 1 to n . Since, the maximum itself is less than equal to 1, it means that the magnitude of each component of the vector \bar{u} has to be less than equal to 1, naturally ok. Since, the infinity norm $\|\bar{u}\|_\infty$ is less than equal to 1 and that gives us a very interesting expression.

(Refer Slide Time: 10:25)

The image shows a whiteboard with handwritten mathematical notes. At the top left, the expression $\bar{z}^T \bar{u}$ is written. To its right, a summation $\sum_{i=1}^n |z_i|$ is circled in purple, with an arrow pointing to it from the text "= $\|\bar{z}\|_1$ ". Above the summation, there is a small blue arrow pointing to the index $i=1$. Below the summation, the text "maximum occurs when" is written in purple. Underneath, the conditions are listed: $|u_i| = 1, i=1, 2, \dots, n$, $\text{sgn}(u_i) = \text{sgn}(z_i)$, and $u_i = \begin{cases} +1 & \text{if } z_i \geq 0 \\ -1 & \text{if } z_i < 0 \end{cases} = \text{sgn}(z_i)$. The whiteboard also has a toolbar at the top and a status bar at the bottom showing "38 / 95".

So, this is less than or equal to summation i equal to 1 to n magnitude z_i and in fact. So, that gives us the expression, that $\bar{z}^T \bar{u}$ is less or equal to summation magnitude z_i . Now, does the maximum occur; yes, occur yes maximum occurs. If you think about it, when magnitude u_i equal to 1 for each i , that is for all i magnitude u_i equal to 1 and the sign of u_i equals sign of z_i .

That is what you are doing is, if z_i is positive, you are setting u_i to be plus 1. If z_i is negative, we are setting u_i to be minus 1, that is u_i equal to plus 1. If z_i is greater than equal to 0 minus 1, if z_i is less than that is u_i is basically equal to, you can say in some sense, sign of z_i all right and in that case, what is this? You can see, the maximum values achieved and what is the maximum value?

(Refer Slide Time: 11:56)

The slide shows a handwritten equation in a box: $\|z\|_{\infty}^* = \|z\|_1$. Below the box, an arrow points to the equation with the text "Dual Norm of ∞ norm = l_1 norm". The slide also has a small "39" at the bottom center.

Maximum value is nothing but the l_1 norm, that is the l_1 norm and therefore, what you observe is something very interesting, what you observe is the dual norm of the infinity norm equals the l_1 norm. So, the dual norm of infinity norm, dual norm of the l_1 infinity norm is the l_1 norm all right. In similarly, you can work out the dual norm of other norms. For instance, what is the dual norm of the l_1 norm and you should be able to convince yourself, that it is indeed the l_1 infinity norm. These are the duals of each alright.

(Refer Slide Time: 12:49)

The slide is titled "#8. DUAL of General Linear Program." and shows the following optimization problem:

$$\begin{aligned} \min & c^T x \\ \text{s.t.} & Gx \leq h \\ & Ax = b \end{aligned}$$

Arrows point from the text "inequality" to the constraint $Gx \leq h$ and from "Equality constraints" to the constraint $Ax = b$. The slide also has a small "40" at the bottom center.

Let us look at another problem, problem number 8 or example number 8, we want to derive the dual optimal problem corresponding to general LP. So, we want to do dual of a general LP or that is your general linear program dual of a general linear program and this can be found. Now, consider your general linear program, that is your minimum c bar transpose x bar subject to the constraint that $G x$ bar is less than or equal to h bar and $A x$ bar equals b bar. Now, the dual problem; now what we want to do is this is a general LP; general LP means, it has of course, these are component wise inequality constraints ok.

So, each element on the left, each element of the vector on the left is less than equal to each element on the right that is of h bar. So, this is, so general LP means it has inequality constraints and it has, does inequality constraints and it has equality constraints.

(Refer Slide Time: 14:31)

Linear Program

$$\begin{aligned} \min & \quad c^T x \\ \text{s.t.} & \quad Gx \leq h \\ & \quad Ax = b \end{aligned}$$

} DUAL Problem

inequality

Equality Constraints

$$L(x, \lambda, \mu) = c^T x + \lambda^T (Gx - h) + \mu^T (Ax - b)$$

$\lambda \geq 0$

Lagrange multiplier for inequality constraints

And therefore, if you look at this Lagrangian, you can formulate remember to find the dual problem.

So, we want to find the dual problem for this. This is L bar of x bar λ bar μ bar and the dual problem of this is a c bar transpose x bar plus λ bar, $G x$ bar minus h bar plus μ bar transpose $A x$ bar minus b bar. Of course, with each, Lagrange multiplier λ_i associated with the inequality constraints greater than equal to 0 ok. These are Lagrange multiplier these are the

Lagrange multipliers for the inequality constraints, and we have seen something similar, before we have seen the linear program with only equality constraint, but not in equality constraint.

(Refer Slide Time: 15:57)

The image shows a handwritten derivation of the Lagrangian function $L(\bar{x}, \bar{\lambda}, \bar{\mu})$. The derivation starts with the expression:

$$L(\bar{x}, \bar{\lambda}, \bar{\mu}) = \bar{c}^T \bar{x} + \bar{\lambda}^T (G\bar{x} - \bar{h}) + \bar{\mu}^T (A\bar{x} - \bar{b})$$

Annotations include:

- A green circle around $\bar{\lambda} \geq 0$ with the text "Lagrange multiplier for inequality constraints".
- Blue arrows pointing to $\bar{\lambda}^T (G\bar{x} - \bar{h})$ and $\bar{\mu}^T (A\bar{x} - \bar{b})$ with the text "For each inequality constraint" and "one for each equality constraint".

The derivation then simplifies the expression:

$$= \bar{x}^T \bar{c} + (\bar{x}^T G^T - \bar{h}^T) \bar{\lambda} + (\bar{x}^T A^T - \bar{b}^T) \bar{\mu}$$

$$= \bar{x}^T (\bar{c} + G^T \bar{\lambda} - \bar{h}^T \bar{\lambda})$$

Of course, these are vectors because, you have for each 1 Lagrange multiplier for each lambda bar, one Lagrange multiplier for each inequality constraint, that is if G is m cross n, then you have m inequality constraints all right. So, therefore, you have m Lagrange multipliers alright and nu bar is basically, 1 Lagrange multiplier for each equality constraint, that is if A is m tilde cross n tilde then u bar is; obviously, m tilde. So, ok. So, 1 Lagrange multiplier or each equality 1 for each equality constraint and now I can recast this. I can recently rewrite this just write this as x bar transpose take the transpose of the whole thing because, its scalar quantity.

So, I can simply write the take the transpose of this correct x bar transpose into c bar plus x bar transpose into well, I can write this as x bar transpose c bar plus well x bar transpose G transpose, minus h bar transpose into lambda bar plus x bar transpose A transpose minus b bar transpose into n u bar and collecting all the terms in x bar transpose, this is c bar plus G transpose lambda bar minus h bar transpose lambda bar. I am sorry G transpose lambda bar plus A transpose mu bar minus this will be the constant terms h bar transpose lambda bar plus b bar transpose mu bar.

(Refer Slide Time: 18:00)

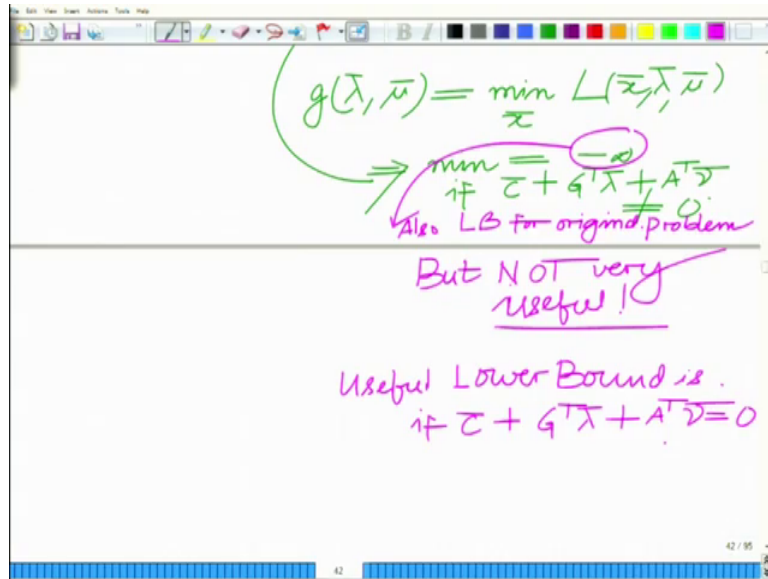

The image shows a whiteboard with handwritten mathematical equations. At the top, there is a term $+(\bar{x}^T A^T - b^T) \bar{y}$. Below it, the Lagrangian function is defined as $L(\bar{x}, \bar{\lambda}, \bar{\mu}) = \bar{x}^T (c + G^T \bar{\lambda} + A^T \bar{y}) - (h^T \bar{x} + b^T \bar{y})$. An arrow points from the linear term $-(h^T \bar{x} + b^T \bar{y})$ to the text "Affine in \bar{x} ". Below this, the dual function is defined as $g(\bar{\lambda}, \bar{\mu}) = \min_{\bar{x}} L(\bar{x}, \bar{\lambda}, \bar{\mu})$. A second arrow points from the minimum operation to the result: $\min_{\bar{x}} = \begin{cases} -\infty & \text{if } c + G^T \bar{\lambda} + A^T \bar{y} \neq 0 \\ \end{cases}$. The whiteboard also has a toolbar at the top and a footer with "41 / 95".

And now you will observe something interesting, what you will observe is this is a linear function of x or in fact, this is Affine in \bar{x} ok, which means now, now we have our Lagrangian, remember correct if you look at the duality theory.

Now, we have to find G of λ bar μ bar, which is the minimum of the Lagrangian for each value of λ bar comma μ bar that is for each Lagrange that is for at every point it corresponds to every λ bar corresponding to a particular λ bar μ bar. There is Lagrange multiplier vectors, we have to find the minimum with respect to x bar.

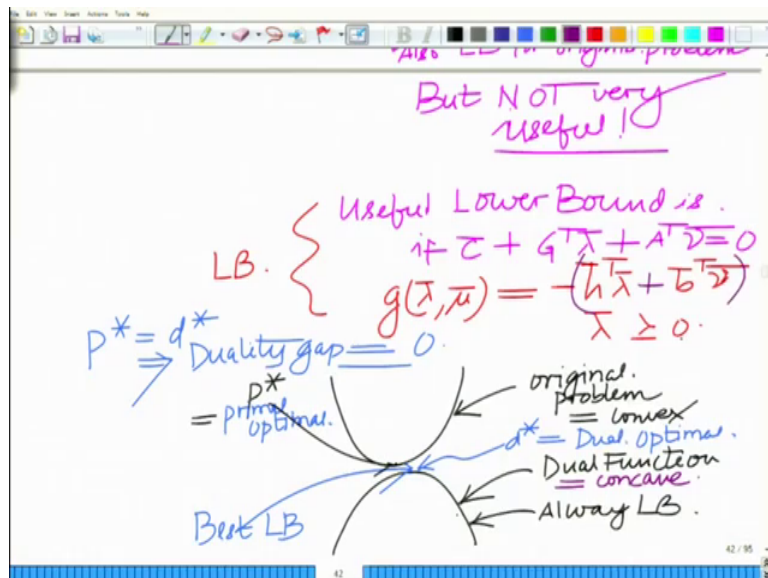

Now, you can see this is a line in x bar, which, implies the minimum equals minus infinity if the linear term, that is a coefficient that is the, that is a vector multiplying x bar is not equal to 0. Then I can take it to minus infinity by choosing appropriate values of x because, it is a hyper plane in x , correct. This is the equation of a hyper plane alright and by choosing if this coefficient vector multiplying x bar is not 0. Then by choosing x is appropriately, I can always take it to any straight line or hyper plane I can always take it to minus infinity ok. So, this is minus infinity if c bar plus G transpose λ bar plus A transpose μ bar is not equal to 0.

(Refer Slide Time: 20:15)

On the other hand something interesting. Now, minus infinity is also a lower bound. Remember G of this thing λ bar μ bar is always a lower bound. So, minus infinity also lower bound for the original problem, but it is not very interesting because, minus infinity is a lower bound for any optimization problem, but it is not very; let us put it useful it is not very useful. So, instead we want a certain lower bound, which is more useful and that you will get by considering the other case, when \bar{c} plus G transpose λ bar plus A transpose.

(Refer Slide Time: 21:40)

So, a more useful lower bound more useful, let us say lower bound is when, if $\bar{c} + G^T \bar{\lambda} + A^T \bar{\nu} = 0$ then the lower bound if this is a constant. Therefore, $G \bar{\lambda} + \bar{\mu}$ in this context, in this case $G \bar{\lambda} + \bar{\mu}$ equals well, what is it? It reduces to the constant, which is $-\bar{h} + \bar{b}^T \bar{\lambda} + \bar{m}^T \bar{\nu}$ ok, and therefore, now, so this is a lower bound, this is a lower bound. What does this mean?

This means that, for any $\bar{\lambda}$ and of course, $\bar{\lambda}$ has to be remembered, that constraint is always their $\bar{\lambda}$ has to be comprehensive greater than equal to 0. This is all the Lagrange multipliers associated with the inequality constraint have to be greater than equal to; so, for any such $\bar{\lambda}$ satisfying this constraint alright, $G \bar{\lambda} + \bar{\mu}$ is a lower bound for the original optimization and therefore, what is the best lower bound, that is the dual problem.

So, the best lower bound, which means something that, is close. So, everything is a lower bound, what is the best lower bound something, that is the maximum value. So, everything; so you can, if you remember the picture, this is the original problem, which is convex. This is the dual function and this is always a lower bond ok, for any the entirely lies below the optimal value.

So, this is the primal optimal and this write here is d^* , which is the dual optimal and this is what we call as the best lower bound because, its closest it is the one, that is closest to the optimal optimum value p^* of the primal, primal optimization problem and of course, if $d^* = p^*$ that implies, that the duality gap is 0 the primal optimal equals the dual optimal ok, $p^* = d^*$ implies duality gap equal to 0.

(Refer Slide Time: 24:35)

DUAL Problem opt val d^*

$$\max. \quad g(\lambda, \mu) = -(\bar{h}^T \lambda + \bar{b}^T \mu)$$

Concave!

$$\text{st.} \quad \bar{c} + G^T \lambda + A^T \mu = 0$$

$$\lambda \geq 0$$

And therefore, the dual problem is basically the best lower bound, which is maximizing $\bar{g}(\lambda, \mu)$, which in this case, is well \bar{c} plus G transpose λ bar, I am sorry, which is in this case is and observe that the dual function, this is concave ok. So, G of λ bar μ ; so, this is minus \bar{h} bar transpose λ bar minus \bar{b} bar transpose μ bar minus \bar{h} bar transpose λ bar. I am sorry or you can write plus, but this is brackets minus \bar{h} bar transpose λ bar plus \bar{b} bar transpose μ bar negative of the whole thing ok. That is the constant.

So, minus \bar{h} bar transpose λ bar, I am just going to write it like this minus \bar{h} bar transpose λ bar minus of \bar{h} bar transpose λ bar plus \bar{b} bar transpose μ bar, but of course, you have constraints subject to the constraints that remember, this is only when \bar{c} plus G transpose λ bar plus A transpose μ bar equal to 0, and of course, each λ bar is component each λ is greater than equal to 0 or λ bar is component wise greater than equal to 0 and this is the dual problem and you can see this is concave because, it is a linear function linear in λ bar μ bar.

So, it is both convex and concave or it in particular the dual problem is concave and therefore, you can find d^* this gives solution equal to the optimum value equal to d^* , which is, in fact, less than equal to p^* , but in this case d^* will be exactly equal to p^* because, this is a linear program which is a convex optimization problem. So, in general for a convex optimization problem strong duality holds, which implies that d^*

equal to p star ok, all right. So, we will stop here and continue with other examples in the subsequent modules.

Thank you very much.
