

# Applied Linear Algebra for Signal Processing, Data Analytics and Machine Learning

Professor. Aditya K. Jagannatham

Department of Electrical Engineering

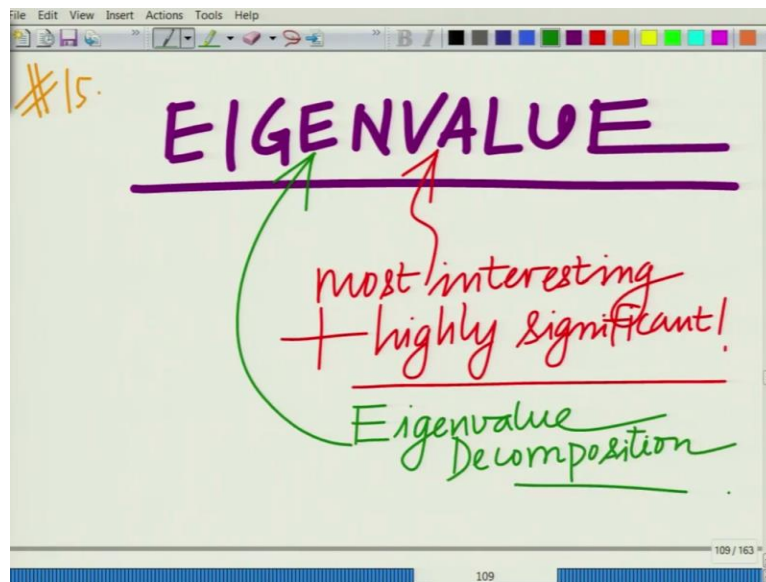

Indian Institute of Technology, Kanpur

Lecture No. 15

**Eigenvalues: Definition, Characteristics equation,  
Eigenvalue Decomposition**

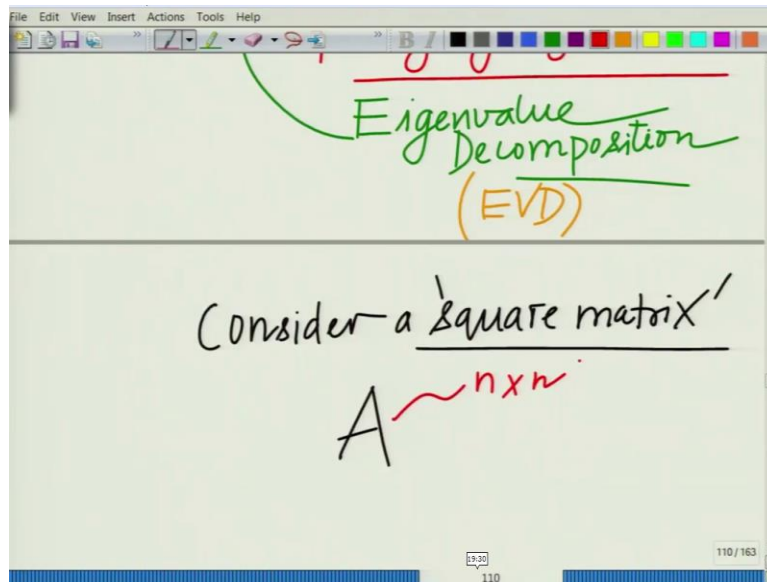

Hello, welcome to another module in this massive open online course and in this module let us start looking at another very important aspect in the whole of Linear Algebra and that is the concept of an Eigenvalue and the Eigenvalue decomposition, I think this is perhaps one of the most impactful and one of the most important concepts in the entire domain of Linear Algebra and Matrix Algebra.

(Refer Slide Time: 00:43)

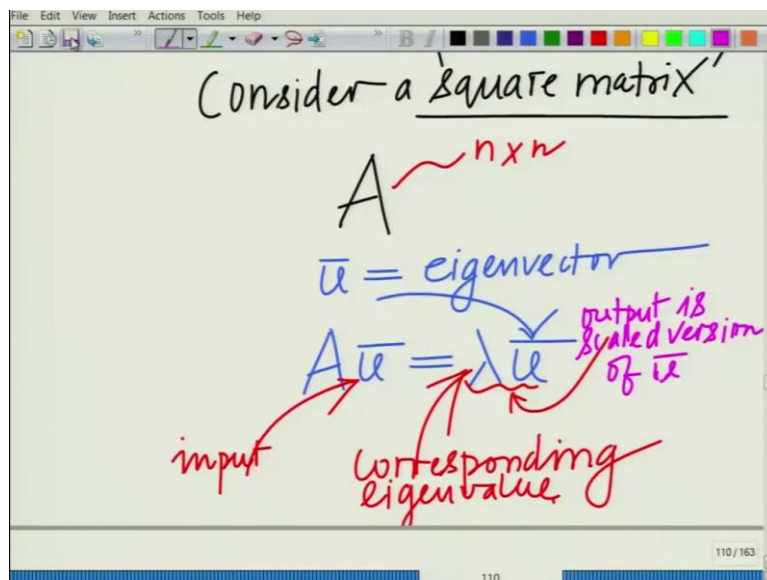

So, this concept of Eigenvalue which is so fascinating and has so many applications, probably one of the most central most I would say this is one of the most interesting plus highly significant because of the large number of applications of this, as one of the most interesting and highly impactful, I would say. And this Eigenvalue is also related to the Eigenvalue Decomposition, these are essentially more or less interlink. Eigenvalue decomposition as in if you find the Eigenvalues and the Eigenvectors that gives the Eigenvalue decomposition.

(Refer Slide Time: 01:49)

So, which is also often you will see abbreviated as EVD popularly sometimes in literature books and papers people call this as EVD that is the Eigenvalue Decomposition. And this is as I have told you, I would like to explain this very clearly because this is one of the most important concepts that we are probably going to study in this entire course now, what is the concept of an Eigenvalue? This is defined for a square matrix Eigenvalue decomposition, consider a square matrix, consider a square matrix Eigenvalues are defined only for square matrices that is one thing that is let us say we have a matrix A which is an n cross n matrix.

(Refer Slide Time: 02:44)

Now,  $\bar{u}$  is the Eigenvector which is an  $n$  dimensional vector we call this an Eigenvector if it satisfies the property that  $A\bar{u}$  equals some  $\lambda$  times  $\bar{u}$ . So, we call  $\bar{u}$  as the corresponding Eigenvector and  $\lambda$  as the corresponding Eigenvalue. So,  $\bar{u}$  so, if you have square then you have square matrix  $A$ , there is a vector  $\bar{u}$  so that is  $A$  times  $\bar{u}$  is simply a scaled version of  $\bar{u}$  that is  $\lambda$  some scalar quantity  $\lambda$  times  $\bar{u}$ .

So, you can think of this as system input  $\bar{u}$  output is simply it is not a it is looks it is identical to  $\bar{u}$  except that it is simply a scaled version. So, you have the input to this system you can think of this as an input to the system this is the input  $\bar{u}$  and output is scaled version of  $\bar{u}$ , scaled by  $\lambda$ . This is one way to think about this. Output is scaled version output is scaled version of  $\bar{u}$ ,  $A\bar{u}$  equals  $\lambda$  times  $\bar{u}$ . So, the vector  $\bar{u}$  is known as the Eigenvector and this quantity  $\lambda$  is known as the Eigenvalue of this square matrix, of the square matrix  $A$ .

(Refer Slide Time: 04:39)

The image shows a whiteboard with the following handwritten mathematical steps:

$$A\bar{u} = \lambda\bar{u}$$

$$\Rightarrow A\bar{u} - \lambda\bar{u} = 0$$

$$(A - \lambda I)\bar{u} = 0$$

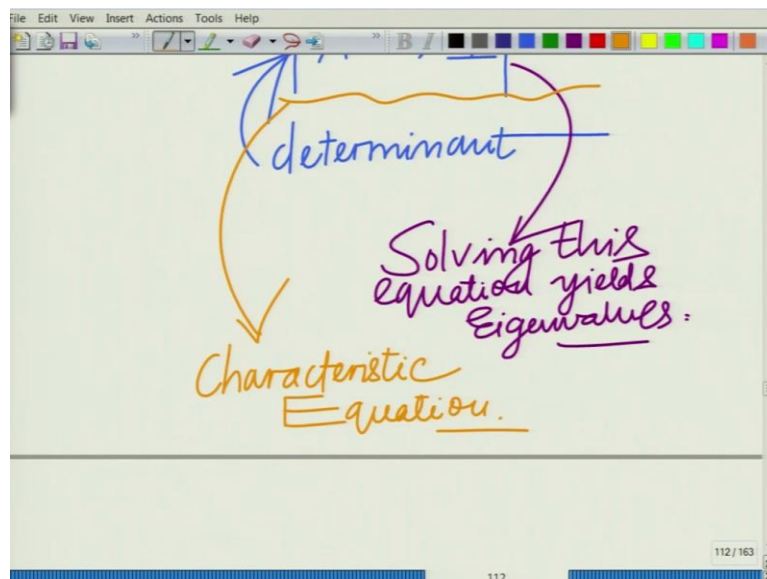

Below the last equation, there are two lines of text with arrows pointing to the matrix  $(A - \lambda I)$ :

- $\Rightarrow A - \lambda I$  is singular
- $\Rightarrow |A - \lambda I| = 0$  nontrivial null space

So, this implies note that, this can be simplified as follows  $A\bar{u}$  equals  $\lambda$   $\bar{u}$ . This essentially implies that we write it in big font, this essentially implies that  $A\bar{u}$  minus  $\lambda$   $\bar{u}$  equal to 0 and this essentially implies now, you look at this which means  $A$  minus  $\lambda$   $I$  times  $\bar{u}$  equal to 0. And now, if you look at this what does this mean this means that this matrix this is you look at this matrix, this has a non trivial null space,  $\bar{u}$  is not 0 this has a non trivial null space.

Remember that is the concept that we have seen this as a non trivial null space, is a singular matrix  $A - \lambda I$  equal to 0 at singular matrix. This means that  $A - \lambda I$  is a singular matrix and this essentially implies that the determinant of  $A - \lambda I$  equal to 0 this essentially implies that the determinant of  $A - \lambda I$  equal to 0.

(Refer Slide Time: 06:09)

And in fact, now, therefore, the lambdas can be found as the solution to this equation that is the determinant of  $A - \lambda I$ , remember this is the determinant and the lambdas can be found as a solution of this equation and this equation is termed as solving this yields the solving

this equation yields the Eigenvalues. So, solving this equation yields the Eigenvalues very good. Solving this equation yields the Eigenvalues.

And this equation is known as the Characteristic Equation that is if you look at this determinant of A minus lambda equal to 0, this is known as the Characteristic. This is known as the Characteristic Equation corresponding to the matrix A.

(Refer Slide Time: 07:30)

The image shows two screenshots of a presentation slide. The top screenshot, labeled '113 / 163', contains the following handwritten text:

Example:

$$A = \begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix}$$

$A \sim 2 \times 2$  and  $I \sim 2 \times 2$

$$A - \lambda I = \begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

The bottom screenshot, labeled '114 / 163', continues the work:

$$= \begin{bmatrix} 2 - \lambda & 3 \\ 2 & 1 - \lambda \end{bmatrix}$$
$$\left| \begin{bmatrix} 2 - \lambda & 3 \\ 2 & 1 - \lambda \end{bmatrix} \right| = 0$$

Let us look at a simple example, example. So, hope you have been able to follow what we are saying so, far you have the square matrix A, Au bar equal to lambda u bar if there is a vector u

bar that satisfies this that is the output is a scaled version of the input,  $\bar{u}$  is the Eigenvector  $\lambda$  is the corresponding Eigenvalue and the Eigenvalues can be found as the solution of the characteristic equation which is given by determinant  $A - \lambda I = 0$ .

Let us look at a simple equation, let us look at a simple example to understand this for instance, let us look at the example  $A = \begin{pmatrix} 2 & 3 \\ 1 & 2 \end{pmatrix}$  and now, what is  $A - \lambda I$   $A - \lambda I$  is  $A$  minus  $\lambda$  times identity of course,  $I$  have to take the identity of the same size as  $A$  so,  $A$  is  $2 \times 2$  which means,  $I$  will also be  $2 \times 2$  so, we have  $A - \lambda I$ , so, you have  $\begin{pmatrix} 2-\lambda & 3 \\ 1 & 2-\lambda \end{pmatrix}$  which is essentially now you take this, this is essentially going to be  $\begin{vmatrix} 2-\lambda & 3 \\ 1 & 2-\lambda \end{vmatrix}$  that is  $A - \lambda I$  now the determinant of  $A - \lambda I$  that is essentially determinant of  $\begin{vmatrix} 2-\lambda & 3 \\ 1 & 2-\lambda \end{vmatrix}$ , this is essentially equal to  $(2-\lambda)(2-\lambda) - 3$ . Now, we have to set this equal to 0 remember this set this equal to 0.

(Refer Slide Time: 09:39)

The image shows a digital whiteboard with a toolbar at the top. The handwritten text in purple ink is as follows:

$$\Rightarrow (2-\lambda)(1-\lambda) - 6 = 0$$
$$\Rightarrow 2 - 3\lambda + \lambda^2 - 6 = 0$$
$$\Rightarrow \lambda^2 - 3\lambda - 4 = 0$$

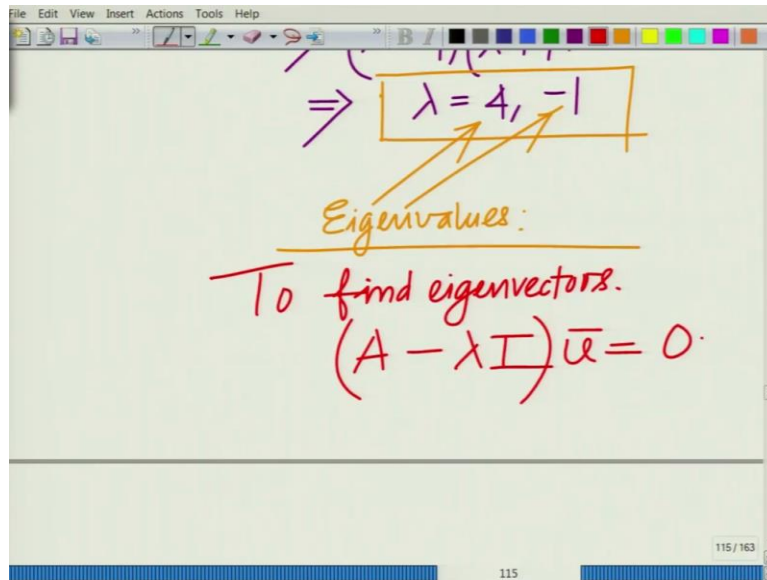

---

$$\Rightarrow (\lambda - 4)(\lambda + 1) = 0$$
$$\Rightarrow \lambda = 4, -1$$

The final result  $\lambda = 4, -1$  is enclosed in a yellow rectangular box. The whiteboard interface includes a toolbar with various drawing tools and a status bar at the bottom showing '115' and '115 / 163'.

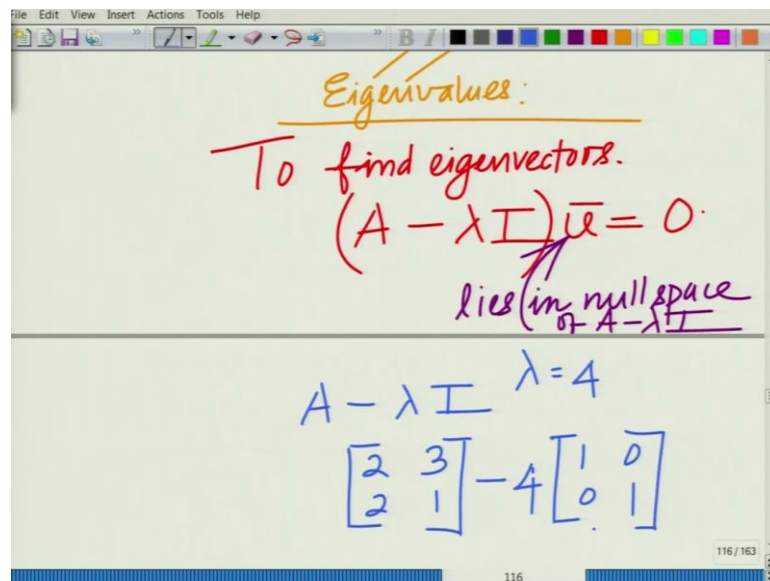

This implies essentially that  $(2 - \lambda)(2 - \lambda) - 6 = 0$ , this implies that  $2 - 3\lambda + \lambda^2 - 6 = 0$ . This implies that  $\lambda^2 - 3\lambda - 4 = 0$ , this implies  $\lambda - 4$ , this essentially implies  $\lambda - 4$  into a  $\lambda + 1 = 0$ , this implies that  $\lambda = 4$  comma  $-1$ . So, this is essentially what this implies. So, this is essentially what this implies.

(Refer Slide Time: 10:35)

So, these are the Eigenvalues lambda equal to 4 lambda equal to minus 1. So, you have a quadratic equation solving that yields the 2 Eigenvalues, very good. Now, to find the Eigenvectors remember we have to solve remember Eigenvectors satisfy the equation A minus lambda I times u bar equal to 0 that is if you look at the Eigenvector u bar that lies in the null space of the matrix A minus lambda I, where lambda is the corresponding Eigenvalue.

(Refer Slide Time: 11:24)

So, the u bar lies in the null space of A minus lambda I. So, u bar lies in the null space of A minus lambda I now, let us take this A minus lambda I set a set lambda equal to 4. So, that will

be your, your 2 comma 2 2 and 3 1 minus lambda times I or minus 4 times 1 0, 0 1 which if you look at this now,

(Refer Slide Time: 12:06)

The image shows a whiteboard with handwritten mathematical work. At the top, it says  $A - \lambda I$  with  $\lambda = 4$  written above it. Below this, the matrix calculation is shown:  $\begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix} - 4 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} -2 & 3 \\ 2 & -3 \end{bmatrix}$ . The next line shows the equation  $(A - \lambda I)\vec{u} = 0$  leading to a system of equations:  $\begin{bmatrix} -2 & 3 \\ 2 & -3 \end{bmatrix} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \vec{0}$ . This is followed by the two equations:  $-2u_1 + 3u_2 = 0$  and  $2u_1 - 3u_2 = 0$ .

This is essentially you will have minus 2 3 2 minus 2 3 to minus 3 now, we said A minus lambda u bar equal to 0. So, A minus lambda I times u bar equal to 0 this implies that if I substitute this matrix minus 2 3 2 minus 3 u bar,  $u_1, u_2$  equal to 0 this implies you will see minus 2  $u_1$  plus 3  $u_2$  equal to 0 2  $u_1$  minus 3  $u_2$  equal to 0 remember look, look at this, this is basically the first equation scaled by minus 1 gives you the second equation and this is also always a characteristic of when you try to solve the null space there will always be a free variable.

(Refer Slide Time: 13:16)

Handwritten notes on a whiteboard:

$u$  is Eigenvector.  
 $\Rightarrow \alpha u$  is also eigenvector!  
 $Au = \lambda u$   
 $A(\alpha u) = \alpha Au$   
 $= \alpha \lambda u$   
 $= \lambda(\alpha u)$

$2u_1 - 3u_2 = 0$   
 $\Rightarrow u_1 = \frac{3u_2}{2}$   
 $u_2 = 2 \Rightarrow u_1 = 3$

$\bar{u} = \begin{bmatrix} 3 \\ 2 \end{bmatrix}$

$A \bar{u} = \begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} 3 \\ 2 \end{bmatrix} = \begin{bmatrix} 12 \\ 8 \end{bmatrix} = 4 \begin{bmatrix} 3 \\ 2 \end{bmatrix} = 4 \bar{u}$   
 $A\bar{u} = \lambda \bar{u}$

So, in this case I can only have till 1 equation  $2u_1 - 3u_2 = 0$  which means  $u_1$  equals  $\frac{3}{2}u_2$ . If I set  $u_2 = 2$ , this implies  $u_1 = 3$ . So, I get one of the vectors as  $u = (u_1, u_2)$  that is  $(3, 2)$ . And in fact if we say this is not unique if I said  $u_2 = 1$ , in fact if I say  $u_2 = 1$ , I will get  $u_1 = \frac{3}{2}$ . So, the Eigenvector you can see this interesting property of the Eigenvector, Eigenvector is independent of a scaling parameter if you scale it by a constant  $\alpha$  it will still be an Eigenvector.

Because if you look at the property of the Eigenvector  $Ax = \lambda x$  or  $Au = \lambda u$ , if I scale it by  $\alpha$ ,  $A(\alpha u) = \alpha Au = \alpha \lambda u = \lambda(\alpha u)$ . So, if you scale a vector, so, this scaling does not impact the Eigenvector, so,  $\alpha u$  is an Eigenvector implies  $u$  is also an Eigenvector corresponding to the same Eigenvalue. So, if  $u$  is an Eigenvector implies  $\alpha u$  is also an Eigenvector.

So, in fact  $(3, 2)$  will be an Eigenvector if you scalar multiplied both by 2. So,  $(6, 4)$  will also be an Eigenvector so on and so forth. Scaling does not have scaling by any constant  $\alpha$  does not impact at all, it will still be an Eigenvector corresponding to the Eigenvalue  $\lambda$  and therefore, you will see that there is a free variable that I can choose  $u_2$  and  $u_1$  can be determined appropriately or in this case I can also choose  $u_1$  and  $u_2$  will be determined appropriately.

And now, we can do a quick check for instance, let us multiply this Eigenvector by this matrix  $\begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix}$ , this is our matrix A multiplied by this  $\begin{bmatrix} 1 \\ -1 \end{bmatrix}$  which is  $\bar{u}$  that gives you essentially to enter the rest 6, 6 plus 6 12 and 2 into 3 6 6 plus 2 8 which is nothing but 4 times your vector 3 comma 2, 4 is nothing but recognize this is your lambda and this is your  $\bar{u}$ . So, you have very much satisfies the equation  $A\bar{u} = \lambda \bar{u}$ . So, that is very interesting.

(Refer Slide Time: 16:31)

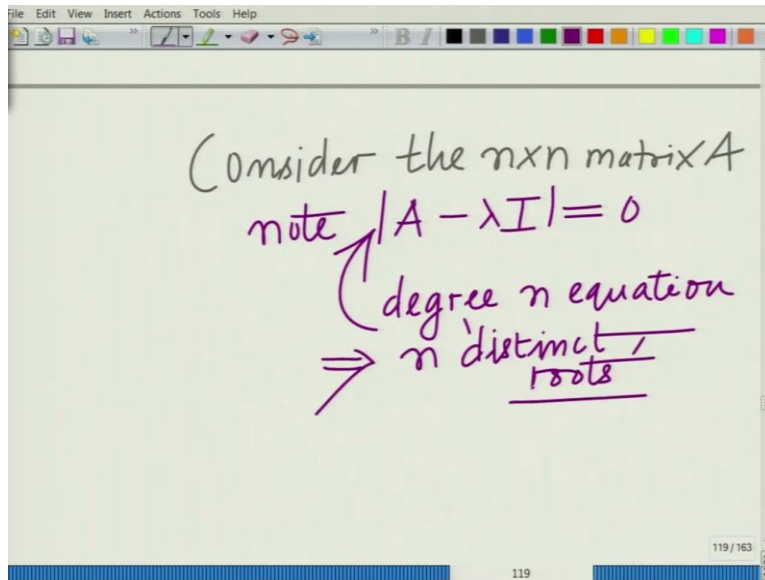

Similarly for  $\lambda = -1$ ,  
 eigenvector  $\bar{u} = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$

$$A\bar{u} = \begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ -1 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix} = -1 \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$

Now, the other Eigenvalue similarly, you can solve this we already solved it even the Eigenvalue is equal to minus 1, 1 similarly, lambda equal to minus 1, Eigenvector  $\bar{u}$  this is given as 1 comma Eigenvector  $\bar{u}$  this is given as 1 comma minus 1 and you have  $A\bar{u} = \begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix} \begin{bmatrix} 1 \\ -1 \end{bmatrix}$  which you can see is essentially just to check this, this is essentially equal to 2 into 1 minus 3. So, this will be minus 1 and 2 minus 1. So, this is 1 which is essentially minus 1 comma 1 minus 1 and this once again you can see this is basically your lambda and this is your vector  $\bar{u}$ ,  $A\bar{u} = \lambda \bar{u}$ .

So, again corresponding to the Eigenvector corresponding to the Eigenvector 1 column corresponding to the Eigenvector 1 comma minus 1, we have the Eigenvalue minus 1. And of course, if 1 comma minus 1 is an Eigenvector 2 comma minus 2 is also an Eigenvector 3 comma minus 3 is also an Eigenvector in fact, for that matter multiplied by minus 3 minus 3 comma 3 is also Eigenvector which is independent of scaling. Now, let us look at the Eigenvalue Decomposition.

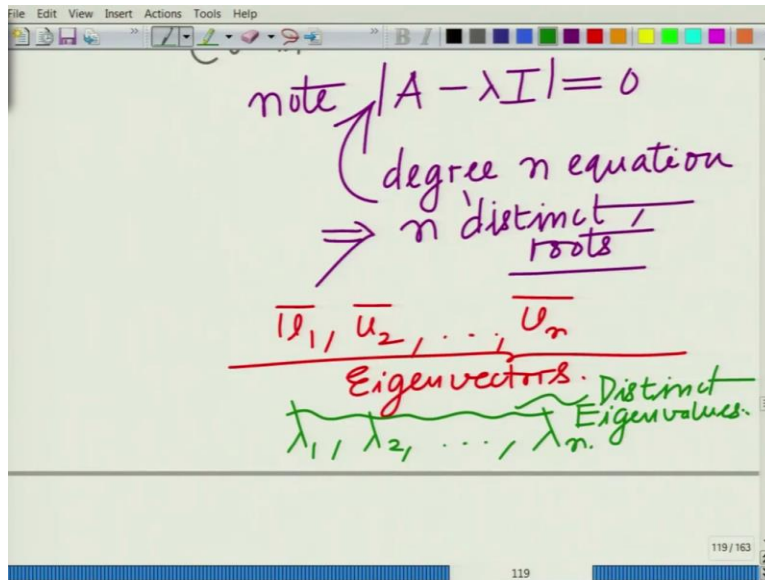

(Refer Slide Time: 18:12)

Consider the  $n$  cross  $n$  matrix  $A$ , consider the  $n$  cross  $n$  matrix  $A$ . Now, note that  $A$  minus  $\lambda I$  is equal to 0 note that this has this is an equation of degree  $n$ , this is an equation of degree  $n$  this implies generally this has  $n$  roots, this has  $n$  roots, let us assume this has  $n$  distinct roots, I will just make it a little subject, the general theory is a little complicated. So, let  $n$  this because we are not interested in going into remember this is not a course on pure Linear Algebra, people, people can talk I mean Eigenvalue when Eigenvalue decomposition is such, such a such an important and such a vast area that people can spend lectures and lectures talking about it.

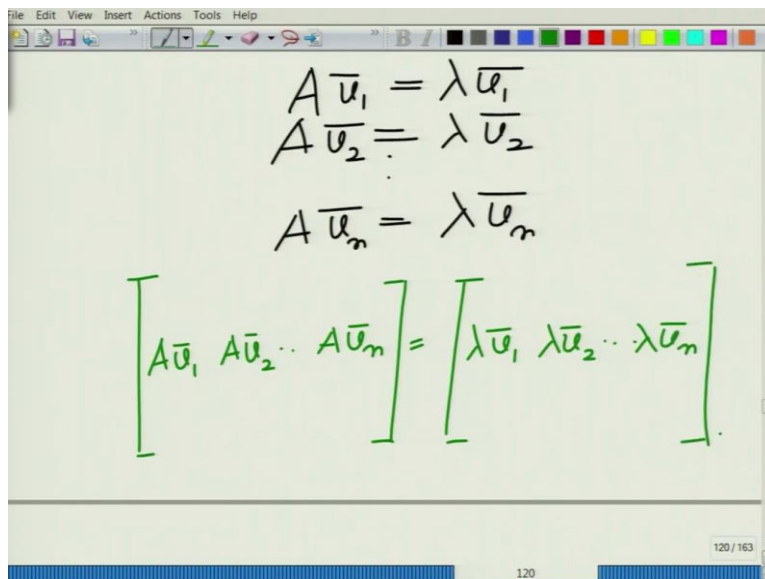

So, we want to simplify our discussion. So, let us consider a simple scenario where this characteristic equation which is an  $n$ th degree polynomial has  $n$  distinct roots and you have the Eigenvectors corresponding to  $n$  distinct roots that is me that makes our discussion simple. So, in that case, once you have these Eigenvectors

(Refer Slide Time: 19:49)

Now, let us let say  $\overline{u_1} \overline{u_2} \dots$  so on  $\overline{u_1}$  bar these denote the Eigenvectors and  $\lambda_1$   $\lambda_2$   $\lambda_n$  denote the  $n$  distinct Eigenvalues because remember the characteristic equation has distinct roots. So, these are the distinct these are the distinct Eigenvalues.

(Refer Slide Time: 20:29)

Then you have you are going to have remember, the Eigenvalue satisfy  $A \overline{u_1}$  Eigenvector satisfy  $A \overline{u_1}$  equals  $\lambda \overline{u_1}$   $A \overline{u_2}$  equals  $\lambda \overline{u_2}$  and  $A \overline{u_n}$  equals  $\lambda \overline{u_n}$ . Now, if I put these stack these together put these together concatenate this as one big matrix remember  $A \overline{u_1} A \overline{u_2} A \overline{u_n}$  I can put these things together as let me just

write this a little bit more clearly I can write this as  $A \begin{bmatrix} \bar{u}_1 \\ \bar{u}_2 \\ \dots \\ \bar{u}_n \end{bmatrix}$ ,  $A \bar{u}_1$ ,  $A \bar{u}_2$  these are the  $n$  columns this is equal to  $\lambda_1 \bar{u}_1$ ,  $\lambda_2 \bar{u}_2$ ,  $\lambda_n \bar{u}_n$ .

(Refer Slide Time: 21:49)

Handwritten mathematical derivation on a whiteboard:

$$\Rightarrow A \begin{bmatrix} \bar{u}_1 \\ \bar{u}_2 \\ \dots \\ \bar{u}_n \end{bmatrix} = \begin{bmatrix} \bar{u}_1 & \bar{u}_2 & \dots & \bar{u}_n \end{bmatrix} \begin{bmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \dots & \\ & & & \lambda_n \end{bmatrix}$$

Annotations:

- $U$  is an  $n \times n$  matrix of Eigenvectors.
- $\Lambda$  is a Diagonal matrix of Eigenvalues.  $n \times n$ .
- The equation  $AU = U\Lambda$  is boxed and labeled as Eigenvalue Decomposition.
- The boxed equation is  $A = U\Lambda U^{-1}$ .

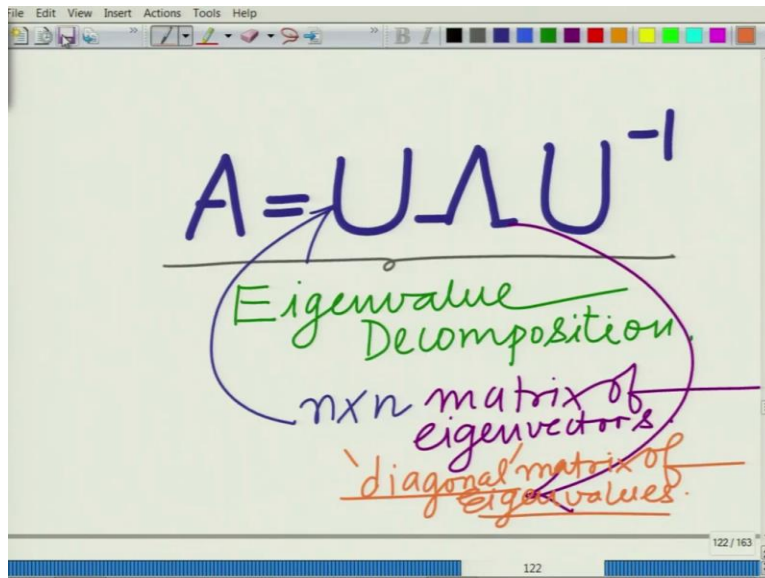

And now, if I pull  $A$  out on the left I can write this as  $A$  times the matrix containing the vectors  $\bar{u}_1$ ,  $\bar{u}_2$  until  $\bar{u}_n$  this is equal to the diagonal matrix the diagonal matrix so, this is equal to  $\bar{u}_1 \bar{u}_2 \bar{u}_1$  times what is here is the diagonal matrix  $\lambda_1 \lambda_2, \lambda_n$  and you can see this holds that is this is nothing but  $\lambda_1 \bar{u}_1$ ,  $\lambda_2 \bar{u}_2$ ,  $\lambda_n \bar{u}_n$ . So, I can this is  $A$  times if I now call this as the matrix  $U$ , which is essentially an  $n$  cross  $n$  matrix this is a  $n$  cross  $n$  matrix of Eigenvectors, this is also  $U$ .

Now this is an interesting matrix this is a  $\lambda$  which is essentially you can see this is the diagonal matrix containing the Eigenvalues this is important, this is the diagonal matrix of Eigenvalues this is the diagonal matrix of Eigenvalues then you have at this  $U$  is the  $n$  cross  $n$  matrix this is also  $n$  cross  $n$  this is a diagonal matrix and this  $U$  is the  $n$  cross  $n$  matrix of Eigenvectors this is the  $n$  cross  $n$  matrix of Eigenvectors and what we have shown is that you have  $AU$  equals  $U$  times  $\lambda$  where  $\lambda$  is a diagonal matrix of Eigenvalues and this essentially now take  $U$  to the right.

That is, you can show that  $U$  is invertible and as I have said we are not let us assume that  $U$  is invertible. So, as I said we are not going to go into the finer details of this that is when is  $U$  going to be invertible and so on. And then, you can write that equal to  $U \lambda U^{-1}$  and this is

known as the Eigenvalue Decomposition. This is essentially known as the Eigenvalue Decomposition. This interesting thing is known as the Eigenvalue Decomposition and this is something that is very interesting, which is essentially you have the, you have we are writing this as let me just write this with a very big font.

(Refer Slide Time: 24:37)

The image shows a digital whiteboard with the equation  $A = U\Lambda U^{-1}$  written in blue ink. Below the equation, the text "Eigenvalue Decomposition" is written in green. Underneath that, "n x n matrix of eigenvectors" is written in purple, and "diagonal matrix of eigenvalues" is written in orange. A purple circle highlights the entire equation and the first two lines of text. The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help) and a toolbar with various drawing tools. The page number "122 / 163" is visible in the bottom right corner.

Because this is something that going to be A equal to u lambda u inverse, this is something that is very, very interesting and this is what we are calling as the this is what we are calling as the Eigenvalue Decomposition. This is essentially something that is very interesting and so, this is your u, which is the n cross n matrix of Eigenvectors and the most interesting matrix is this lambda, which is the diagonal matrix of this is the diagonal, this is what is interesting that diagonal matrix of Eigenvalues of this lambda is essentially a diagonal and this is something that is very, very fundamental and you will see this everywhere.

Wherever you have applications of matrices such as Signal Processing, Machine Learning, Data Analysis and so on and so forth. These applications are huge and applications this wide variety of applications that is the property of Eigen the principle of Eigenvalues. And this Eigenvalue decomposition has applications, it is ubiquitous it has applications everywhere from big data to signal processing to machine learning applications are everywhere.

And this is one of the most important components, one of the most important I would say decompositions and one of the most important concepts, let them square matrix A can be written

as  $A = U \Lambda U^{-1}$ , where  $U$  is the matrix of Eigenvectors and  $\Lambda$  is no diagonal matrix of Eigenvalues. Excellent.

(Refer Slide Time: 27:06)

The first screenshot shows the following handwritten content:

$$A = \begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix}$$
$$\lambda_1 = 4 \quad \lambda_2 = -1$$
$$\bar{u}_1 = \begin{bmatrix} 3 \\ 2 \end{bmatrix} \quad \bar{u}_2 = \begin{bmatrix} 1 \\ -1 \end{bmatrix}$$
$$U = \begin{bmatrix} 3 & 1 \\ 2 & -1 \end{bmatrix}$$

The second screenshot shows the same content as the first, but with the addition of the diagonal matrix  $\Lambda$  and a note:

$$\Lambda = \begin{bmatrix} 4 & 0 \\ 0 & -1 \end{bmatrix}$$

*Eigenvalues in decreasing order of magnitude.*

Let us look at a simple example we have  $A$ , let us go back to our matrix before we have  $A$  equal to  $\begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix}$ , this is  $\begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix}$ . This is our matrix we have the Eigenvalues  $\lambda_1$  equal to 4  $\lambda_2$  equal to minus 1 and corresponding to these we have the Eigenvectors  $\bar{u}_1$   $\bar{u}_2$   $\bar{u}_1$  equal to 3 comma 2,  $\bar{u}_2$  equal to 1 comma minus 1 therefore, you can form the matrix  $U$  which is the matrix of Eigenvectors which will be 3 comma 2 and you will have 1 comma 1 comma minus 1. And the diagonal matrix of Eigenvalues  $\Lambda$  that we are talking about you

have to write the Eigen all you have to do is you have to write the diagonal matrix there are Eigenvalues on the diagonal so 4 comma minus 1.

Now, the other interesting thing about this is if you look at this we have arranged the Eigenvalues in decreasing order of magnitude, we have the Eigenvalues 4 and minus 1, so, we have arranged the Eigenvalues in decreasing order of magnitude. Although it is not very important. In fact, Eigenvalue decomposition we can write the Eigenvalues of in any particular in any order, but it is usually very useful you will see realize that in many applications, if you write the Eigenvalues in the decreasing order of magnitude that has some significance as we are going to see later.

So, we are writing the Eigenvalues in decreasing order of magnitude we can also say that is a convention Eigenvalues in decreasing order of magnitude, Eigenvalues in decreasing order of magnitude. And now therefore, we have the property.

(Refer Slide Time: 29:32)

Handwritten mathematical derivation on a whiteboard:

$$U = \begin{bmatrix} 3 & -1 \\ 2 & -1 \end{bmatrix}$$

$$U^{-1} = \frac{1}{-5} \begin{bmatrix} -1 & -1 \\ -2 & 3 \end{bmatrix} = \frac{1}{5} \begin{bmatrix} 1 & 1 \\ 2 & -3 \end{bmatrix}$$

Verify!

$$A = U^{-1} \Lambda U$$

$$\begin{bmatrix} 2 & 3 \\ 2 & 1 \end{bmatrix} = \frac{1}{5} \begin{bmatrix} 3 & -1 \\ 2 & -1 \end{bmatrix} \begin{bmatrix} 4 & 0 \\ 0 & -1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 2 & -3 \end{bmatrix}$$

Diagonal matrix of eigenvalues

Now, let us calculate u we already know u inverse. So, we have seen u equals well what is u, u equals 3 2, 1 minus 1 so, u inverse remember this is 2 cross 2 matrix so 1 over the determinant minus 3 minus 2, that is minus 5, swap the diagonal elements to cross 2 matrix inverse we have swapped the diagonal elements minus 1 comma 3 and negative of the off diagonal elements negative of the off diagonal elements, so minus 1 minus 2. And now if you take the negative in front of the minus y inside, so, this becomes 1 over 5, 1 1, 2 minus 3.

And therefore, now you have finally  $A$  equal to  $u \lambda u^{-1}$  which essentially take the constant  $\frac{1}{5}$  outside you can take the constant  $\frac{1}{5}$  outside you can write this as first is  $u$ , that is essentially your  $\begin{pmatrix} 3 & 2 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$  the diagonal matrix of Eigenvalues that is your  $\begin{pmatrix} 4 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$  minus  $\frac{1}{5}$  times  $u^{-1}$ , we remember we have already taken this  $1$  by  $5$  outside. So, that is  $\begin{pmatrix} 1 & 1 & 2 \\ 0 & 2 & 3 \\ 0 & 0 & 1 \end{pmatrix}$  and you can multiply it out and you can ensure that you get the original matrix which is  $A$  which is essentially your remember your  $\begin{pmatrix} 2 & 2 & 3 \\ 0 & 2 & 3 \\ 0 & 0 & 1 \end{pmatrix}$  this is your original matrix  $A$  you can multiply this, so verify this.

So, my suggestion to you is verify this, multiply it out verify this and you can see so, this is basically  $u \lambda u^{-1}$  of course,  $u^{-1}$  will have the  $\frac{1}{5}$  over here and this is essentially the diagonal matrix of Eigenvalues. This is your Diagonal Matrix. This is essentially your diagonal matrix of Eigenvalues and this is the Eigenvalue Decomposition which has several, several applications and each I have already said alluded to at the beginning of this module, that this is easily probably one of the most important concepts in entire Linear Algebra.

So please, I hope you paid attention please go over this if you have not understand anything clearly and understand this completely and assimilate this concept because this has several applications, tremendous applications. So with that, let us stop here and let us continue this discussion in the subsequent modules. Thank you.
