Positive semi-definite (PSD) matrices: definition, properties, eigenvalue decomposition

Hello, welcome to another module in this massive open online course. So, in this module let us start looking at another important class of matrices termed as PSD that is positive semi-definite or PD positive definite matrices which are again very important and arise very frequently in linear algebra.

(Refer Slide Time: 00:33)

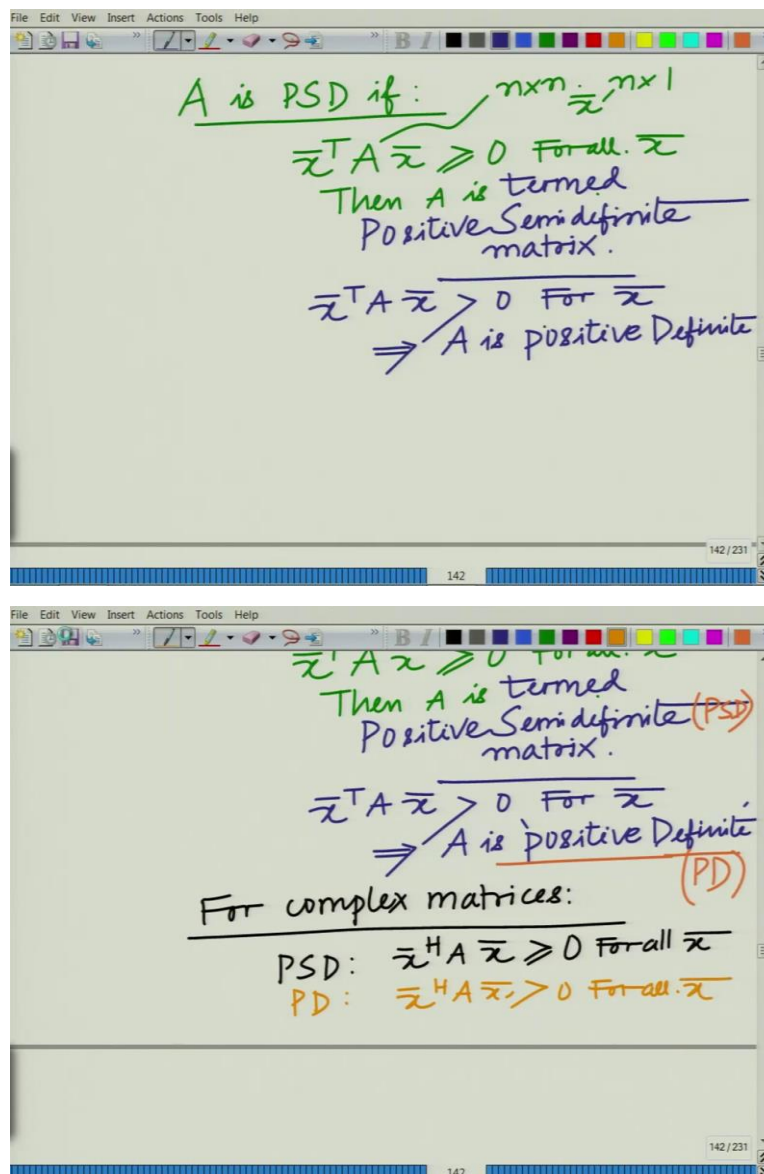

So, we want to start looking at PSD matrices which means, this stands for positive semi-definite matrix (PSD) and we want to also look at positive definite (PD) matrices, what is the meaning of positive and these are related, PD means positive definite matrices. Now, when do we call a matrix as a positive semi-definite matrix? Again, we consider square matrices, consider a square matrix.

In fact, we will consider a symmetric matrix, consider a symmetric square matrix that is if it is a real A equal's A transpose for complex, we will have A equal to A Hermitian that is we are considering a symmetric matrix. What it means is, if it is a real equal to A transpose for complex matrices, we have A equal to A Hermitian that is transpose and complex conjugate, this is also known as Hermitian symmetric. So, you might have also seen this so, this is also known as Hermitian symmetry.

(Refer Slide Time: 03:20)

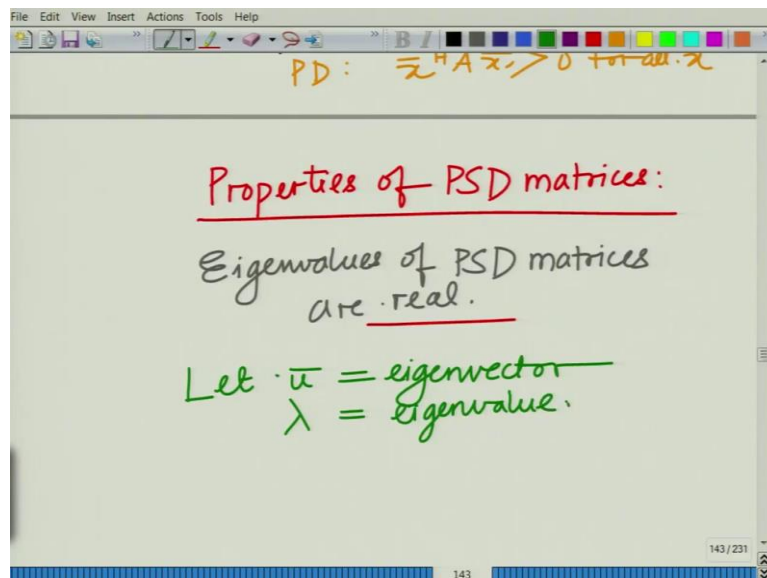

And, we call A is a positive semi-definite matrix, A is positive semi-definite if $\bar{x}^T A \bar{x} \geq 0$ for all \bar{x} , that is if we have an $n \times n$ matrix and \bar{x} is an $n \times 1$ vector. Then, if $\bar{x}^T A \bar{x} \geq 0$ for all \bar{x} , then A is positive semi-definite, A is termed a positive semi-definite matrix.

On the other hand, if for a complex matrix we have or let us put it again for a positive definite matrix $\bar{x}^H A \bar{x} > 0$ for all \bar{x} that is if A is real $\bar{x}^T A \bar{x} > 0$ for all \bar{x} this implies A is a positive definite, this implies A is a positive definite or what we are also calling as a PD matrix. So, positive semi-definite matrix is essentially a PSD and this is essentially your P, positive semi-definite is PSD and this is positive definite is a PD matrix.

So, if \bar{x} transfers all vectors \bar{x} , $\bar{x}^T A \bar{x}$ is always greater than or equal to 0, if that condition holds for all vectors \bar{x} then A is termed a positive semi-definite matrix if it is strictly greater than 0 $\bar{x}^T A \bar{x}$ strictly greater than 0 for all vectors \bar{x} , then it is termed as a positive definite matrix.

Similarly, you might have already guessed for complex matrices. For PSD, we have \bar{x} Hermitian $A \bar{x}$ greater than or equal to 0 for all \bar{x} , and for PD we have \bar{x} Hermitian $A \bar{x}$ greater than 0 for all \bar{x} for all vectors \bar{x} this is what complex matrices that is we have to consider Hermitian, \bar{x} Hermitian $A \bar{x}$ and if it is greater than or equal to 0 PSD for all \bar{x} if it is simply greater than 0, it is strictly greater than 0 for all \bar{x} then it becomes a positive definite matrix.

(Refer Slide Time: 07:16)

Let us look at the properties of positive semi-definite matrices and of course, properties of positive definite matrices are very similar, the inequalities become strict. So, let us look at the properties of positive semi-definite matrices and what is the property of the positive semi-definite matrices? The first property is that the very important property eigenvalue of PSD matrices are real, the eigenvalue of PSD matrices these are real quantities, these are real numbers, this is a very important property of positive semi-definite matrices and we will prove this for the general case of complex, we will consider general complex positive semi-definite matrices and we will show these properties. And this is a fairly important property, let \bar{u} equals eigenvector, and λ equal the corresponding eigenvalue.

(Refer Slide Time: 09:11)

$$A \bar{u} = \lambda \bar{u}$$

$$\bar{u}^H A \bar{u} = \bar{u}^H \lambda \bar{u} = \lambda \|\bar{u}\|^2 \quad (1)$$

Further

$$(\bar{u}^H A \bar{u})^H = (\lambda \|\bar{u}\|^2)^* \quad (1)$$

$$\Rightarrow \bar{u}^H (A^H) \bar{u} = \lambda^* \|\bar{u}\|^2$$

$$A^H = A$$

$$\Rightarrow \bar{u}^H A \bar{u} = \lambda^* \|\bar{u}\|^2 \quad (2)$$

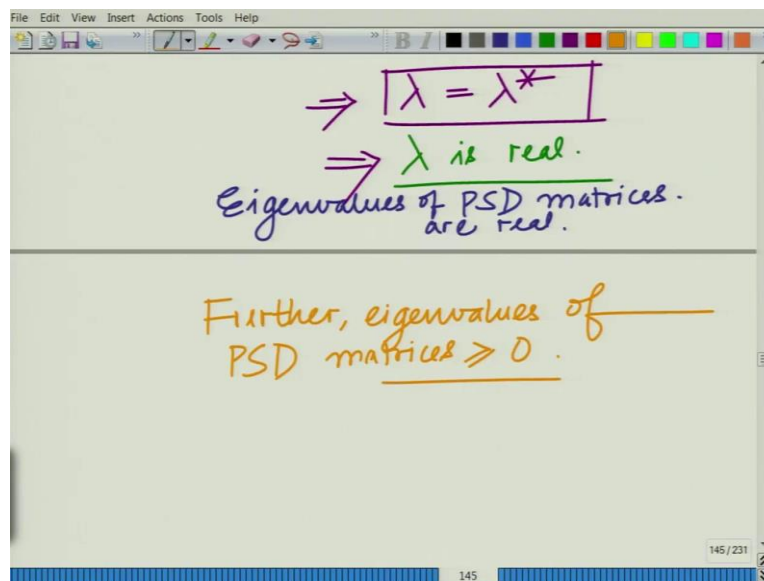

$$\Rightarrow \bar{u}^H A \bar{u} = \lambda \|\bar{u}\|^2 = \lambda^* \|\bar{u}\|^2$$

Such that we have $A \bar{u} = \lambda \bar{u}$, where A is we have said a PSD matrix. Then, $\bar{u}^H A \bar{u}$ is Hermitian if we perform \bar{u}^H Hermitian, $\bar{u}^H A \bar{u}$ this would be $\bar{u}^H A \bar{u}$ Hermitian $\lambda \bar{u}$ which is $\lambda \|\bar{u}\|^2$. Now, further, if you take the conjugate Hermitian on the left, $\bar{u}^H A \bar{u}$ if you take the Hermitian this is equal to λ . So, after that, if you take the Hermitian then you have your Hermitian $\bar{u}^H A \bar{u}$ equal to $\lambda \|\bar{u}\|^2$ you can take the conjugate on the right.

Since it is a scalar quantity, this implies $\bar{u}^H A \bar{u}$ or A Hermitian or rather A Hermitian $\bar{u}^H A \bar{u}$, A Hermitian $\bar{u}^H A \bar{u}$ equals $\lambda \|\bar{u}\|^2$, since, $\|\bar{u}\|^2$ is earlier quantity. Again, we have a symmetric matrix that is A Hermitian equal to A . So, this implies, you can easily see, $\bar{u}^H A \bar{u}$ equal to $\lambda \|\bar{u}\|^2$.

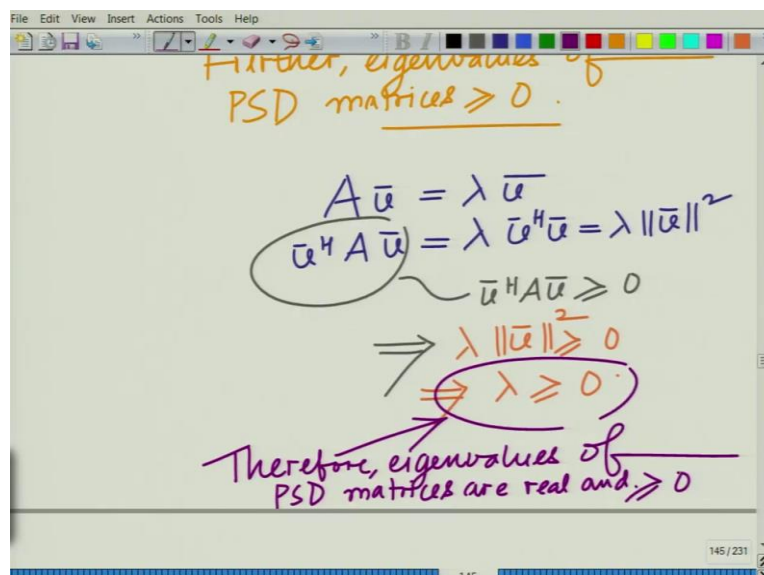

So, if you look at this what we can call as properties 1 and 2. This implies $\bar{u}^H A \bar{u}$ equals $\lambda \|\bar{u}\|^2$ equal to $\lambda^* \|\bar{u}\|^2$ from 1 and 2, from results 1 comma 2.

(Refer Slide Time: 11:44)

And finally, this implies you can see that lambda equals lambda conjugate and therefore, this implies that the eigenvalues, this implies that lambda is real. Therefore, eigenvalues of PSD matrices are real. And further, these eigenvalues are greater than or equal to 0, further, it is not very difficult to see, further, all eigenvalues of PSD matrices are greater than or that is they are non-negative, the eigenvalues of PSD matrices are greater than or equal to 0 and that is also not very difficult to see.

(Refer Slide Time: 13:09)

Follow the same logic, we have matrix A, eigenvector u bar, A u bar equals lambda times u bar, u bar Hermitian A u bar equals lambda u bar Hermitian u bar equal to lambda norm u bar square. Now, you know from the property of the PSD matrices u bar Hermitian A u bar is

greater than or equal to 0 that is the left-hand side is greater than or equal to 0 which means the right-hand side $\lambda \|\bar{u}\|^2$ is also greater than or equal to 0, which implies that $\|\bar{u}\|^2$ we can see is the square norm which is always greater equal to 0 which implies that λ is greater than or equal to 0.

Therefore, this is a very interesting property put together, therefore, eigenvalues of the PSD matrices are real and greater than or equal to 0, these are real and eigenvalues are greater than or equal to 0 that is these eigenvalues are non-negative. The eigenvalues of PSD matrices are essentially non-negative, is a very important and interesting property which has a lot of applications as I already told you because positive semi-definite and positive definite matrices are as frequently and of course, the counterpart for the analogs property for a positive definite matrix will be that eigenvalues are strictly greater than 0 that is eigenvalues are positive because $\bar{u}^H A \bar{u}$ is strictly greater than 0.

Now, let us you can simply replace the weak inequalities by the strong inequalities. Now, the next important property of eigenvalues are that I use the following let me first describe the property.

(Refer Slide Time: 15:28)

Therefore, eigenvalues of PSD matrices are real and ≥ 0

Let \bar{u}_1, \bar{u}_2 be eigenvectors of PSD matrix A , corresponding to distinct eigenvalues λ_1, λ_2

$\lambda_1 \neq \lambda_2$

$A \bar{u}_1 = \lambda_1 \bar{u}_1$
 $A \bar{u}_2 = \lambda_2 \bar{u}_2$

$$A \bar{u}_1 = \lambda_1 \bar{u}_1 \quad (1)$$

$$A \bar{u}_2 = \lambda_2 \bar{u}_2 \quad (2)$$

$$\bar{u}_2^H A \bar{u}_1 = \lambda_1 \bar{u}_2^H \bar{u}_1 \quad \text{real.} \quad (3)$$

$$\bar{u}_1^H A \bar{u}_2 = \lambda_2 \bar{u}_1^H \bar{u}_2$$

$$\Rightarrow (\bar{u}_1^H A \bar{u}_2)^H = \lambda_2^* (\bar{u}_1^H \bar{u}_2)^H$$

$$\Rightarrow \bar{u}_2^H A^H \bar{u}_1 = \lambda_2^* \bar{u}_2^H \bar{u}_1$$

$$A = A^H \text{ symmetric}$$

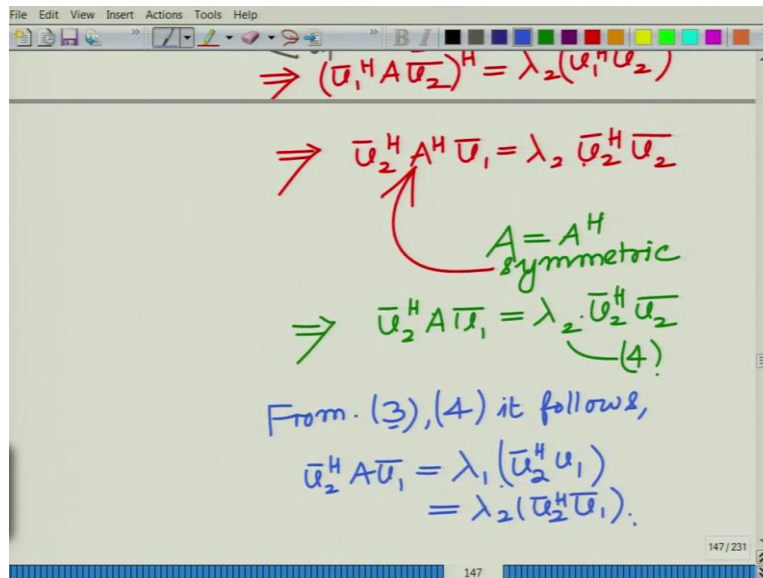

$$\Rightarrow \bar{u}_2^H A \bar{u}_1 = \lambda_2 \bar{u}_2^H \bar{u}_1$$

Let \bar{u}_1, \bar{u}_2 be distinct, be eigenvectors corresponding to distinct eigenvalues, this is important or eigenvectors of PSD matrix A , corresponding to distinct eigenvalues λ_1, λ_2 , that is $\lambda_1 \neq \lambda_2$, these are eigenvectors implies $A \bar{u}_1 = \lambda_1 \bar{u}_1$, $A \bar{u}_2 = \lambda_2 \bar{u}_2$. Then, what is the property that these eigenvectors \bar{u}_1 and \bar{u}_2 satisfy? We are going to see that these satisfy a very interesting property.

Let us start with equation 1, let us start with this perform $\bar{u}_2^H A \bar{u}_1$ this is $\lambda_1 \bar{u}_2^H \bar{u}_1$ and now, let us perform on this $\bar{u}_1^H A \bar{u}_2$ this is $\lambda_2 \bar{u}_1^H \bar{u}_2$. Now, take the complex Hermitian or complex conjugate because these are scalar quantities both of these things are (sca) same. So, $\bar{u}_1^H A \bar{u}_2$ equals, now, we already seen this is a real quantity eigenvalues are real, so this remains λ_2 . So, $\bar{u}_1^H A \bar{u}_2 = \lambda_2 \bar{u}_1^H \bar{u}_2$, so this implies $\bar{u}_2^H A \bar{u}_1 = \lambda_2 \bar{u}_2^H \bar{u}_1$.

Now, once again, A is symmetric which implies $A = A^H$ and this implies $\bar{u}_2^H A \bar{u}_1 = \bar{u}_2^H A^H \bar{u}_1 = \bar{u}_1^H A \bar{u}_2 = \lambda_2 \bar{u}_1^H \bar{u}_2$. And therefore, we have $\lambda_1 \bar{u}_2^H \bar{u}_1 = \lambda_2 \bar{u}_2^H \bar{u}_1$, and therefore, from now, if you look at these equations 3 and 4, so now let us call this 3.

(Refer Slide Time: 19:02)

$$\Rightarrow (\bar{u}_1^H A \bar{u}_2)^H = \lambda_2 (\bar{u}_1^H \bar{u}_2)$$
$$\Rightarrow \bar{u}_2^H A^H \bar{u}_1 = \lambda_2 \bar{u}_2^H \bar{u}_2$$

$A = A^H$
symmetric

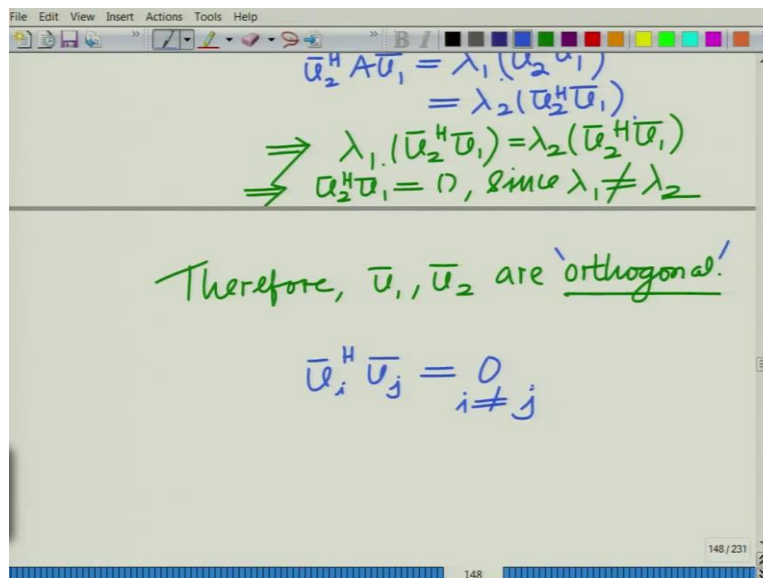

$$\Rightarrow \bar{u}_2^H A \bar{u}_1 = \lambda_2 \bar{u}_2^H \bar{u}_2 \quad (4)$$

From (3), (4) it follows,

$$\bar{u}_2^H A \bar{u}_1 = \lambda_1 (\bar{u}_2^H \bar{u}_1) = \lambda_2 (\bar{u}_2^H \bar{u}_1)$$

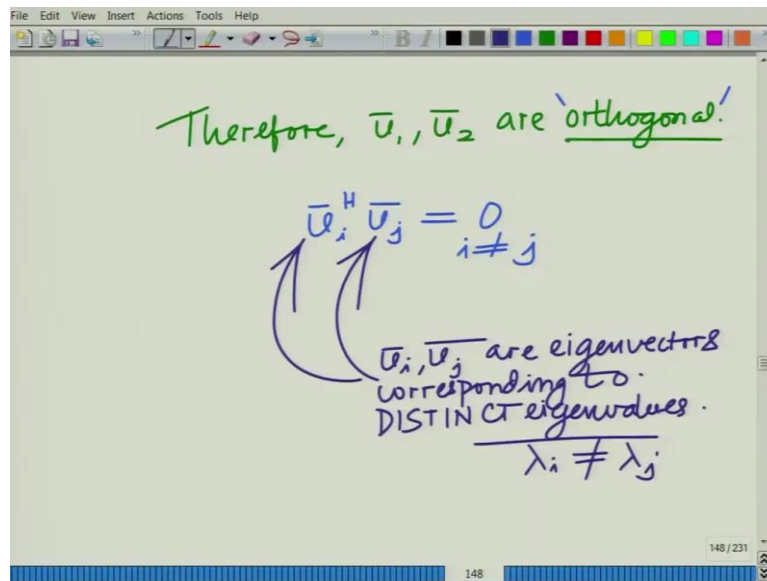

And let us call this equation as equation number 4, from 3 and 4 it follows that \bar{u}_2^H Hermitian $A \bar{u}_1$ equals $\lambda_1 \bar{u}_2^H \bar{u}_1$. From 3, we have this is equal to $\lambda_2 \bar{u}_2^H \bar{u}_1$ Hermitian \bar{u}_1 and from 4 we have the same quantity equal to $\lambda_2 \bar{u}_2^H \bar{u}_1$ Hermitian \bar{u}_1 .

(Refer Slide Time: 19:46)

$$\bar{u}_2^H A \bar{u}_1 = \lambda_1 (\bar{u}_2^H \bar{u}_1) = \lambda_2 (\bar{u}_2^H \bar{u}_1)$$
$$\Rightarrow \lambda_1 (\bar{u}_2^H \bar{u}_1) = \lambda_2 (\bar{u}_2^H \bar{u}_1)$$
$$\Rightarrow \bar{u}_2^H \bar{u}_1 = 0, \text{ since } \lambda_1 \neq \lambda_2$$

Therefore, \bar{u}_1, \bar{u}_2 are orthogonal.

$$\bar{u}_i^H \bar{u}_j = 0 \quad i \neq j$$

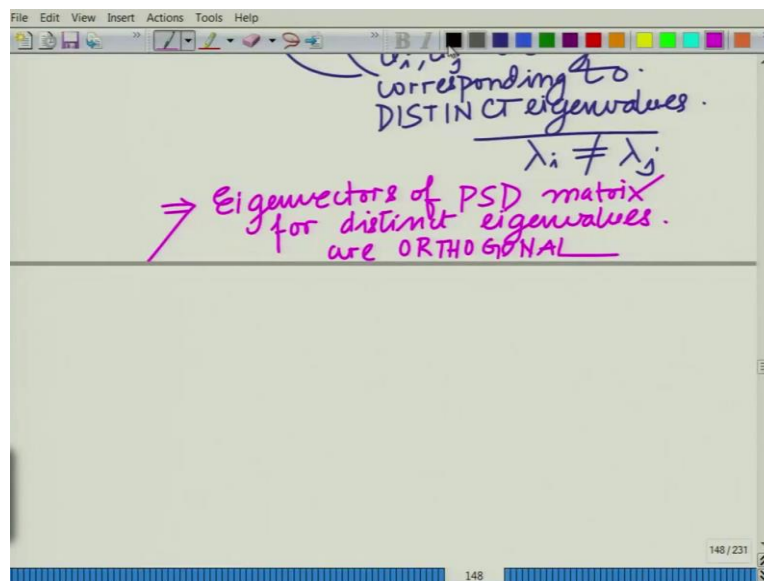

Which implies now, if you look at it something very interesting $\lambda_1 \bar{u}_2^H$ Hermitian u_1 bar equal to $\lambda_2 \bar{u}_2^H$ Hermitian u_1 bar. Now, note these are distinct eigenvalues λ_1 is not equal to λ_2 that is the assumption to begin with. Therefore, this is only possible when $\bar{u}_2^H u_1$ bar is equal to 0. So, this implies \bar{u}_2^H equal to 0, since λ_1 is not equal to λ_2 .

Therefore, what this implies, u_1 bar comma u_2 bar orthogonal and this is a very interesting property, these are orthogonal that is if you look at any u_i bar Hermitian u_j bar is going to be 0 for i not equal to j and these are eigenvectors corresponding to the distinct eigenvalues of a positive semi-definite matrix. Where u_i bar comma u_j bar are eigenvectors corresponding to DISTINCT eigenvalues.

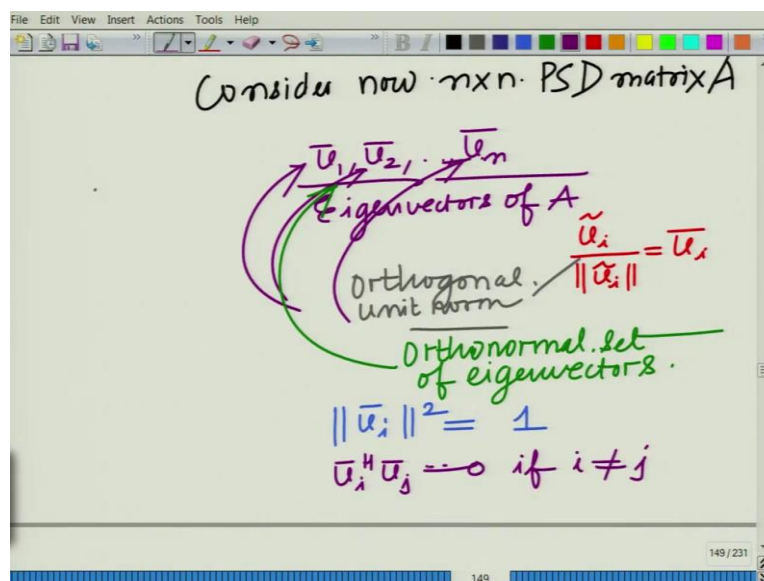

That is you have the eigenvalue λ_i , as eigenvalue λ_j corresponding to u_j λ_i not equal to λ_j . So, λ_i not equal to λ_j , and the corresponding eigenvectors u_i bar Hermitian u_j bar will be orthogonal that is u_i bar Hermitian u_j bar equal to 0, eigenvectors of a positive semi-definite matrix corresponding to distinct eigenvalues are orthogonal.

(Refer Slide Time: 22:20)

So, the result is that the eigenvectors of PSD matrix, so this implies eigenvectors of PSD matrix for distinct eigenvalues are orthogonal that is $\bar{u}_i^H \bar{u}_j = 0$ if $\lambda_i \neq \lambda_j$. This gives a very interesting decomposition.

(Refer Slide Time: 23:11)

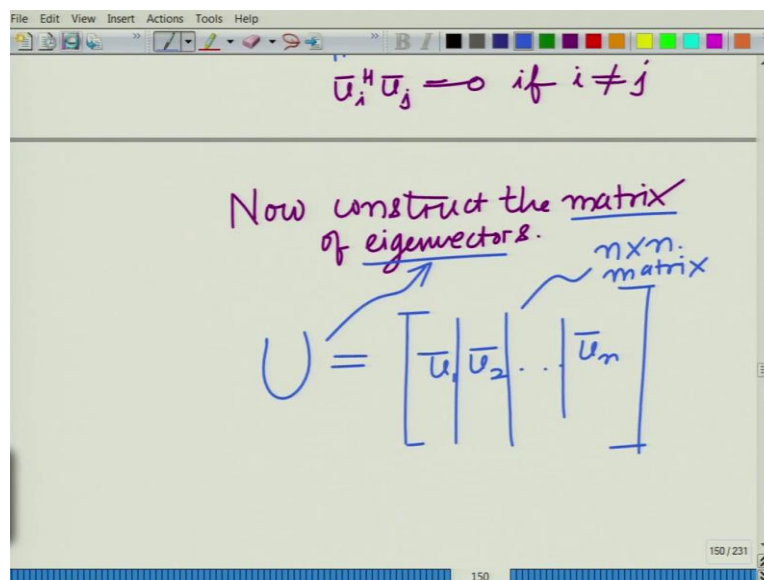

Consider now, $n \times n$ PSD matrix A with eigenvectors are $\bar{u}_1, \bar{u}_2, \dots, \bar{u}_n$, these are the eigenvectors of A , we already seen these are going to be orthogonal. Now, let us also make them unit norm and that is not difficult to see because if \tilde{u}_i an eigenvector which is not unit norm I can always divide it by norm \tilde{u}_i and call that as \bar{u}_i which is essentially a unit norm vector. Remember, if you idealize an eigenvector, scaled version of \tilde{u}_i

\tilde{u}_i is also an eigenvector we have already seen this therefore, \tilde{u}_i divided by norm of \tilde{u}_i is also an eigenvector which we are calling as \bar{u}_i .

So, he can always construct a unit norm eigenvector from. And we have already seen that these different eigenvectors corresponding to the different eigenvalues these are orthogonal so you have orthogonal unit norm that makes it an orthonormal set of eigenvectors. So, we have in a sense, we have an orthonormal set of eigenvectors that exists for a PSD matrix, orthonormal set of eigenvectors because of the positive properties of the PSD matrix such a set of eigenvectors exists.

Which essentially means that again, you might, you will know by this point orthonormal means $\|\bar{u}_i\|^2 = 1$, $\bar{u}_i^H \bar{u}_j = 0$, if $i \neq j$. This we have already seen eigenvectors corresponding to distinct eigenvalues are orthogonal.

(Refer Slide Time: 26:03)

$$U = \begin{bmatrix} | & | & & | \\ u_1 & u_2 & \dots & u_n \\ | & | & & | \end{bmatrix}$$

Diagonal matrix of eigenvalues.

$$\Lambda = \begin{bmatrix} \lambda_1 & & & 0 \\ & \lambda_2 & & \\ & & \dots & \\ 0 & & & \lambda_n \end{bmatrix}$$

Now, construct the matrix of eigenvectors. What is the matrix of eigenvectors? That is we know this is u_1 bar u_2 bar, the columns are given by the eigenvectors, u_1 bar, u_2 bar, u_n bar this will be an n cross n matrix this is your matrix of eigenvectors, where each column is an eigenvector and the corresponding eigenvalues are λ_1 , λ_2 , λ_n , and we can write that as a diagonal matrix.

So, we have the diagonal matrix λ where you have λ_1 , λ_2 , λ_n this is the diagonal matrix of eigenvalues and notice since this u_1 bar, u_2 bar, u_n bar these are orthonormal, it follows that remember from the property of unitary matrices and that is why unitary matrices are important remember, that is what we said because these arise frequently and now, you can see the matrix of eigenvectors of a PSD matrix is a unitary matrix because the columns are orthogonal unit norm it means it satisfies.

(Refer Slide Time: 28:05)

Since, $\bar{u}_1, \bar{u}_2, \dots, \bar{u}_n$
Orthonormal.
 $\Rightarrow U$ is a unitary matrix
 $\Rightarrow U^H U = U U^H = I$
Eigenvalue decomposition of A
 $A = U \Lambda U^{-1}$
 $\Rightarrow A = U \Lambda U^H$
Because U is unitary

$A = U \Lambda U^H$
Eigenvalue decomposition for PSD matrix.

Since, $\bar{u}_1, \bar{u}_2, \dots, \bar{u}_n$ these are orthonormal, this implies U is a unitary matrix which essentially means that U satisfy the property $U^H U = U U^H = I$. Hermitian is identity and therefore, the eigenvalue decomposition of the PSD matrix A , remember any matrix can be decomposed as $U \Lambda U^{-1}$ this is eigenvalue decomposition, U matrix which is a matrix of eigenvectors times Λ which is a diagonal matrix of eigenvalues times U^{-1} .

But now, you see because U is unitary $U^{-1} = U^H$ because U is unitary. So, this implies $A = U \Lambda U^H$ for a positive semi-definite matrix. This is the interesting property for a PSD matrix $A = U \Lambda U^H$. So, U^{-1} becomes U^H , this is essentially the EVD or what we call as the eigenvalue

decomposition for PSD matrix, this is the eigenvalue decomposition for a positive semi-definite matrix that is for the general square matrix it can be written as $U \Lambda U^{-1}$, but for positive semi-definite and of course, for also a positive definite matrix this becomes $U \Lambda U^H$.

(Refer Slide Time: 31:09)

U for PSD matrix

$$\begin{aligned}
 A &= U \Lambda U^H \\
 &= U \Lambda^{1/2} \Lambda^{1/2} U^H \\
 &= U \Lambda^{1/2} (\Lambda^{1/2})^H U^H \\
 &= (U \Lambda^{1/2}) (U \Lambda^{1/2})^H \\
 &= \tilde{A} \tilde{A}^H
 \end{aligned}$$

$\begin{bmatrix} \sqrt{\lambda_1} & & \\ & \sqrt{\lambda_2} & \\ & & \dots \\ & & & \sqrt{\lambda_n} \end{bmatrix}$

$$\begin{aligned}
 &= U \Lambda^{1/2} \Lambda^{1/2} U^H \\
 &= U \Lambda^{1/2} (\Lambda^{1/2})^H U^H \\
 &= (U \Lambda^{1/2}) (U \Lambda^{1/2})^H \\
 &= \tilde{A} \tilde{A}^H
 \end{aligned}$$

$A = \tilde{A} \tilde{A}^H$
 $\tilde{A} = U \Lambda^{1/2}$
Cholesky Factorization.

Let us look at another small property, so you have $A = U \Lambda U^H$ which I can write as $U \Lambda^{1/2} \Lambda^{1/2} U^H$. What is this $\Lambda^{1/2}$? This is the diagonal matrix of eigenvalues, eigenvalues are real. So, I can take the square root, so I can write $\Lambda^{1/2} = \begin{bmatrix} \sqrt{\lambda_1} & & \\ & \sqrt{\lambda_2} & \\ & & \dots \\ & & & \sqrt{\lambda_n} \end{bmatrix}$. This is the diagonal matrix containing the square root of eigenvalues and naturally these are real.

So, I can also write this as a $\lambda^{1/2}$, $\lambda^{1/2}$ Hermitian U Hermitian which is essentially $U \lambda^{1/2}$ times $U \lambda^{1/2}$ Hermitian. Therefore, this implies this is $A \tilde{A}$, $A \tilde{A}$ Hermitian, so I can write any positive semi-definite matrix A can be expressed as it can be decomposed as $A \tilde{A}$, $A \tilde{A}$ Hermitian, where one possible value of A equals $U \lambda$ raised to the power of half.

So, any positive semi-definite matrix A can be decomposed as the product of two matrices that is $A \tilde{A}$ into the Hermitian of its, $A \tilde{A}$ into $A \tilde{A}$ Hermitian. And this is termed as the Cholesky factorization of a positive symmetry and this is very helpful. The Cholesky factorization has a very important role to play in Data Analytics, Machine Learning, Signal Processing this that is you have a positive semi-definite matrix.

And that can be that has positive eigenvalues, whether it is non-negative eigenvalues and therefore, from the properties, of course, orthogonal eigenvectors and so on and so forth. And you can write it as $A U \lambda U$ Hermitian. And essentially what has followed is you can write essentially any positive semi-definite matrix as $A \tilde{A}$ times $A \tilde{A}$ Hermitian. So, it is very similar to a kind of a square root decomposition of a positive real number.

So, if I have a positive real number, x , I can write it as square root of x into square root of x , this is roughly something similar. It is not exactly that, of course, because this generalizes this concept of matrices, and of course, we have the Hermitian it is not exactly $A \tilde{A}$ into $A \tilde{A}$, but it is rather $A \tilde{A}$ into $A \tilde{A}$ Hermitian. So, this is a very, very interesting. So, let us get decomposition positive definite matrices, the decompositions their eigenvalues their eigenvectors arise very, very frequently in all applications in Linear Algebra, Machine Learning, Data Analytics and so on and so forth. So, let us pause here and we will continue in the subsequent modules. Thank you very much.
