SVD application in MIMO wireless technology: Spatial-multiplexing and high data rates

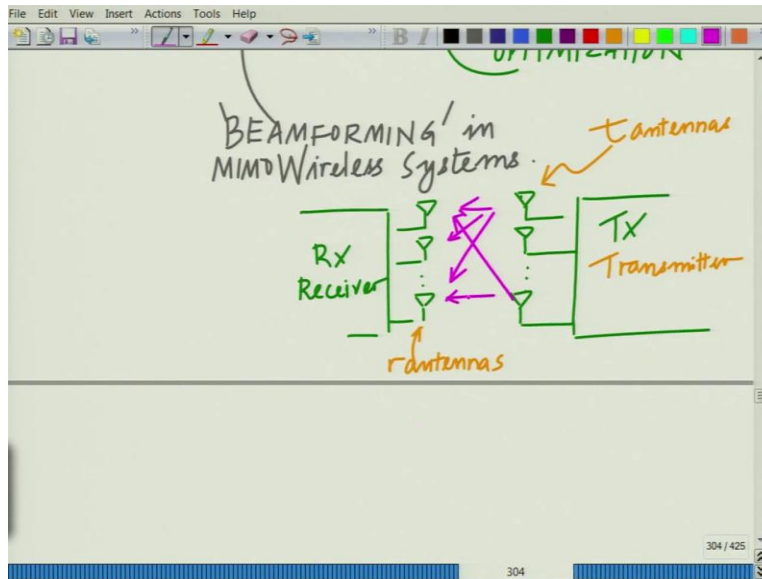

Hello. Welcome to another module in this massive open online course. So we are talking about the singular value decomposition, we have looked at it and we have noted, it is a very important concept for matrix manipulation, a very important tool rather for handling matrices and manipulating matrices. Let us look at applications, some of the interesting applications of this SVD concept and one of the most interesting applications is in the context of, once again, MIMO wireless communication.

(Refer Slide Time: 00:47)

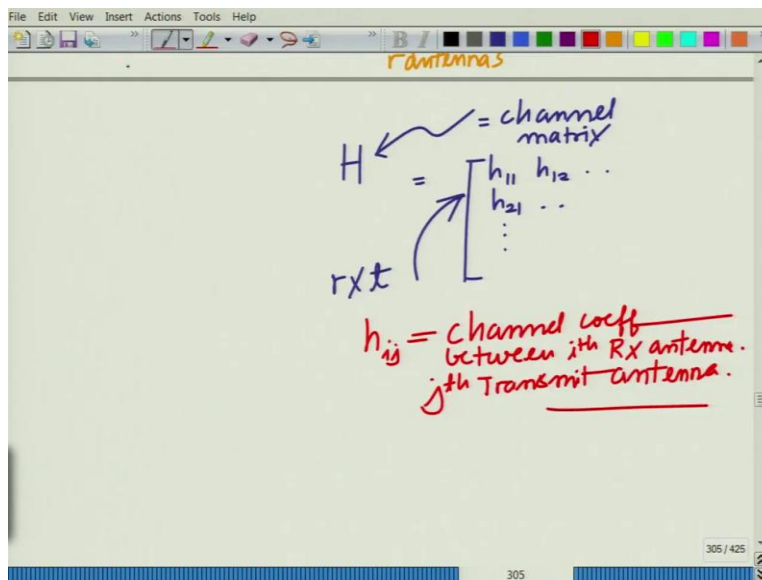

So let us look at SVD specifically for MIMO systems and how SVD helps in the optimization. We are going to eventually look at a very important part of MIMO optimization. In fact, SVD is used for Beam Forming, the idea is that SVD, this can be employed for what we call as Beam Forming, as we have looked at in several times, that is, Beam Forming in wireless systems, especially MIMO wireless systems.

(Refer Slide Time: 1:52)

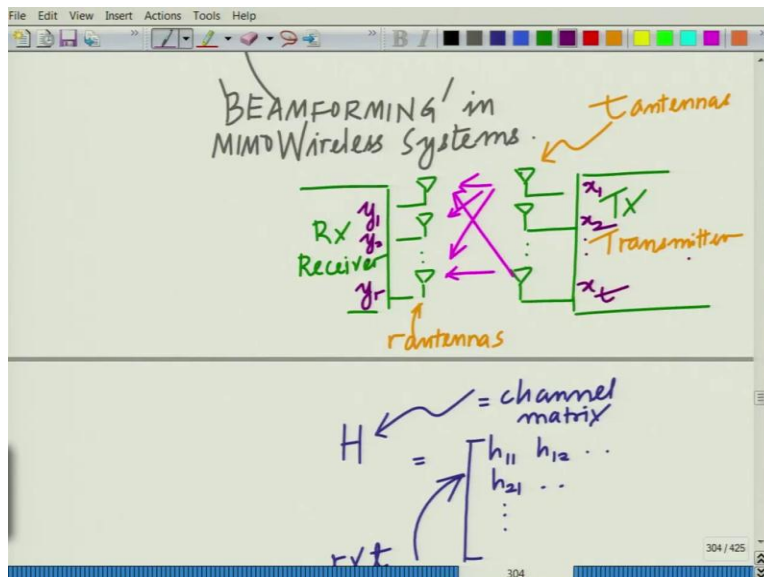

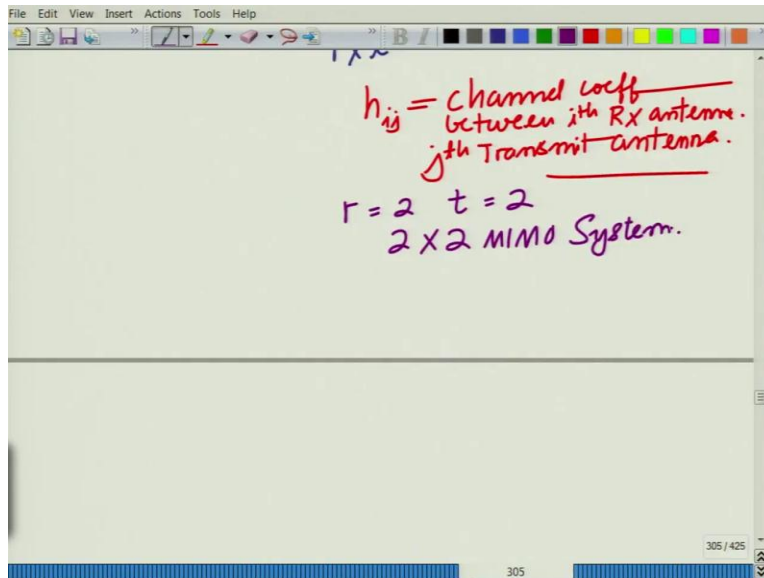

Let us again look at a typical MIMO system, which is basically, has multiple antennas at the receiver and multiple antennas at the transmitter. So you have the receiver, you have the transmitter, you have r antennas at the receiver, t antennas at the transmitter and then you have the channel coefficients where we know that we have the channel matrix. H denotes the channel matrix.

(Refer Slide Time: 2:56)

This is the channel matrix which is of the form, h_{11} h_{12} h_{21} , so on. And this is an r cross t channel matrix, r cross t channel matrix which contains the channel coefficients. H_{ij} is the channel coefficient between the i th receive antenna and the j th transmit antenna. So if you look at H_{ij} , H_{ij} is the channel coefficient between the i th receive antenna and j th transmit antenna.

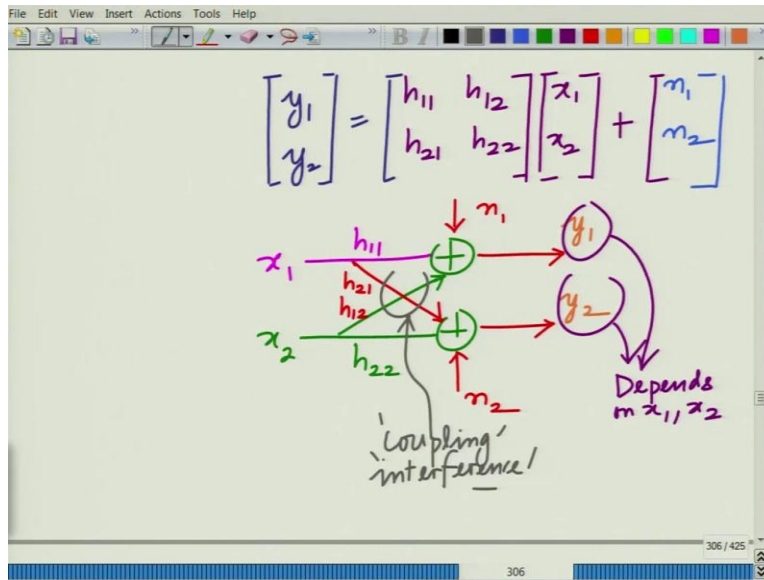

(Refer Slide Time: 4:21)

Now, let us look at a typical MIMO system. For instance, let us consider r equal to 2, t equal to 2, this is termed a 2 cross 2 MIMO system. Now, in this 2 cross 2 MMIMO

system, now, we have the outputs across the receive antenna, let us call these as y_1 , y_2 , y and we have the inputs which are the transmit symbols, x_1 , x_2 , x t.

(Refer Slide Time: 4:52)

Now, the 2 cross 2 MIMO system model, you have two outputs, y_1 comma y_2 . You can write these as, well, the channel coefficients, h_{11} , h_{12} , h_{21} , h_{22} times x_1 x_2 plus the noise which is n_1 , n_2 . Now, let us draw a schematic diagram for this. So let us say, you have the symbol, that is your x_1 . And then you are essentially multiplying this by the channel coefficient, h_{11} and then you have the symbol x_2 , which you are multiplying by the channel coefficient h_{22} .

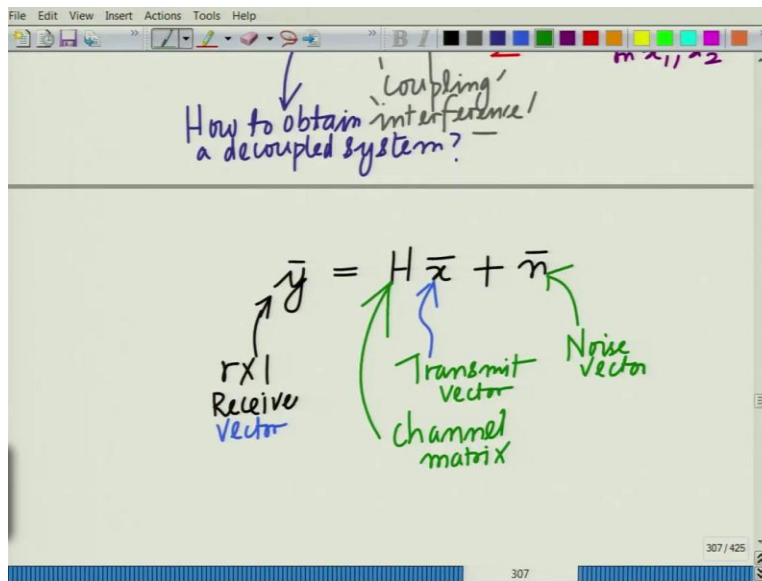

In addition, x_2 , you multiply by h_{12} , this is h_{12} , and x_1 by h_{21} and this is your noise n_1 , this is your noise n_2 and then you have the outputs which are your y_1 and y_2 . And therefore if you look at this, you can see clearly that y_1 depends both, on x_1 and x_2 . Similarly, y_2 depends both, on x_1 and x_2 . So there is a sort of coupling between these two systems, so there is interference, is what I mean by that.

So you look at this, y_1 depends on x_1 , x_2 and so on both. y_1 , y_2 depends on x_1 , x_2 , so there is coupling. So if you look at these arrows, this part, this denotes what we call as the coupling. So these systems are coupled or, basically, there is interference between x_1 and

x2. x1 and x2 interfere with each other, you can also talk of this as some kind of cross talk between these two channels.

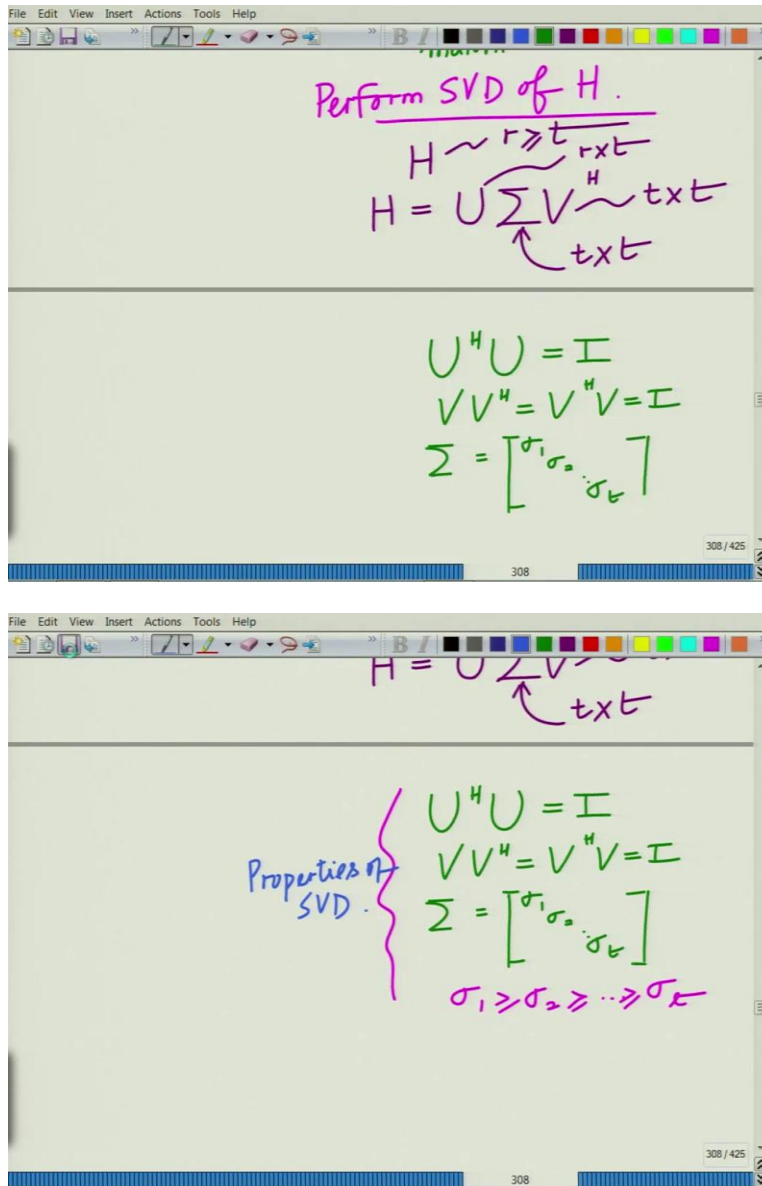

And naturally, if we have to determine x1 and x2 at the receiver, one has to resolve this thing. One has to remove the interference. Now, how to go from this coupled system, can we go from this coupled system to a decouple, how to obtain a decoupled system.

(Refer Slide Time: 8:08)

The question that we want to ask here is, how to obtain a decoupled system? And that is where we use the SVD. Now, let us look at the channel. Now, this is our model \bar{y} equals $H \bar{x}$ plus \bar{n} . This is our receive vector, r dimensional, containing the symbols. So this is our receive vector, this is our transmit vector, and this is our channel matrix, and this is the noise vector. Now, what we do over here is first, perform, so this is our channel matrix, perform the SVD of the channel matrix. So this is what we start with.

(Refer Slide Time: 9:45)

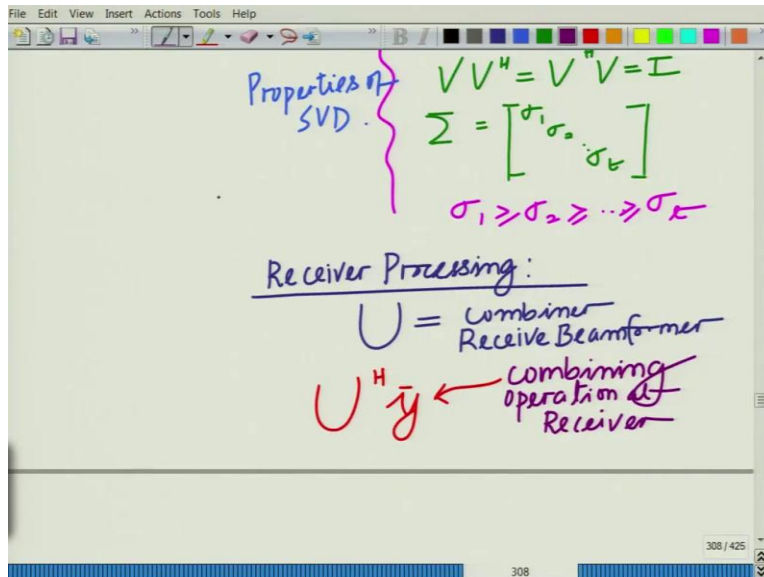

So we perform, we start by performing, in this journey of obtaining a decoupled system, we start by performing the SVD, singular value decomposition of the channel matrix H. And let us again consider a system with r greater than equal to t, number of receive antennas greater than equal to number of transmit antennas.

We can write the SVD as $U \Sigma V^H$, where U is, as we have seen, this is r cross t, this is t cross t and this is a t cross t matrix. And these satisfy the properties, quick recollection, $U^H U = I$, $V V^H = V^H V = I$.

identity, sigma is a diagonal matrix comprising of the singular values which are non-negative and these are arranged in decreasing order. So this is roughly, if you recall, these are the properties of the singular value decomposition.

(Refer Slide Time: 11:38)

Now, at the receiver, receiver processing in the MIMO system. At the receiver, we perform, so we, U is the combiner, we call this as the combiner matrix or the receive Beam Former, which implies that at the receiver we perform U Hermitian y bar. So this is basically, the combining operation at the receiver.

(Refer Slide Time: 12:45)

$$U^H \bar{y} = U^H (H \bar{x} + \bar{n})$$

$$U^H \bar{y} = U^H (U \Sigma V^H \bar{x} + \bar{n})$$

$$\tilde{y} = \Sigma V^H \bar{x} + U^H \bar{n}$$

$$(\tilde{y}) = \Sigma V^H \bar{x} + \tilde{n}$$

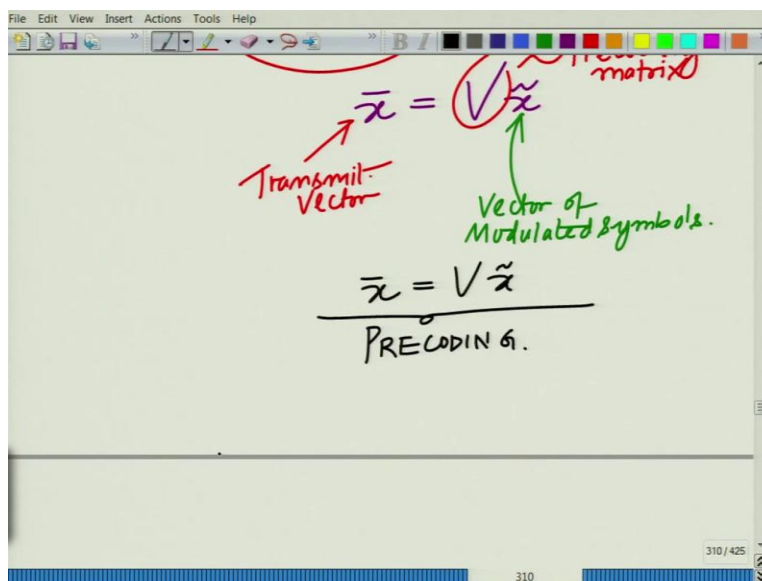

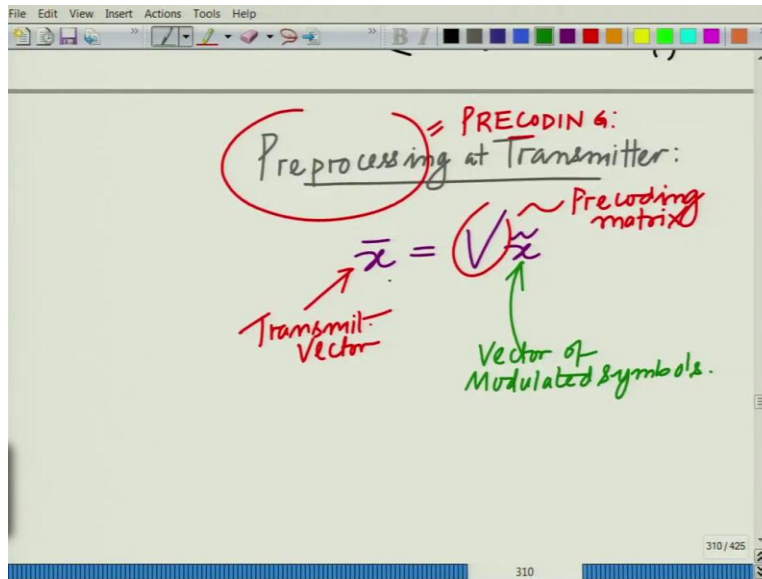

Output obtained on combining:

Therefore, now, once you use this in the MIMO model, you have U Hermitian \bar{y} equals U Hermitian H \bar{x} plus \bar{n} . Now, substitute for H equals U Σ V Hermitian, so this is U Hermitian U Σ V hermitian \bar{x} plus \bar{n} . Now, we know, U Hermitian U is Identity, U is a semi-unitary matrix, that is, a matrix of left singular vectors. Using that property, now, this U Hermitian U is Identity, this reduces to simply, very interestingly, this reduces to Σ V Hermitian \bar{x} plus U Hermitian \bar{n} , let us call this is a \tilde{y} .

Now, U Hermitian is t cross r , \bar{y} is r cross 1 which implies \tilde{y} , this is going to be your t cross 1 vector, so \tilde{y} equals and U Hermitian \bar{n} , let us call this as \tilde{n} , so we have \tilde{y} equals Σ V Hermitian \bar{x} plus \tilde{n} . So this is the model. So this is after, this is the \tilde{y} , this is the combiner, combined vector. That is, output obtained after receive combining.

This is the output obtained after the combining operation at the receiver. Now, at the transmitter what we do is something interesting. At the transmitter, even prior to transmission, we also pre-process. Now, combining is the post-processing. In fact, in the MIMO system we also do pre-processing, that is at the transmitter.

(Refer Slide Time: 15:06)

So what is the pre-processing? The processing, the pre-processing at the transmitter. So what happens here is this is your transmit vector \bar{x} , this is generated as \bar{x} equals V times \tilde{x} . Now, this pre-processing, this is also known as a pre-coding. This is an important operation in MIMO. This is also known as condition or pre-conditioning or basically pre-coding. And this is basically, V is basically, your pre-coding matrix. So you have \bar{x} that is a vector of transmit symbols x_1, x_2, \dots, x_t and you have the vector of, modulator, the actual modulated information symbols, that is $\tilde{x}_1, \tilde{x}_2, \dots, \tilde{x}_t$.

These can be for instance receiver BPSK, QPSK and so on. And we pre-code them, that is, multiplied by the pre-coding matrix V . The pre-coding matrix V acts on this modulated symbols to produce the transmit symbol vectors, \bar{x} . So this is a pre-coding matrix, then think of \bar{x} as the transmit vector. And this is your vector of modulated symbols. And this is your pre-coding operation. \bar{x} equals, so this the vector of modulated symbols and this \bar{x} equals $V \tilde{x}$. You can think of this as pre-coding. So this is pre-coding.

(Refer Slide Time: 17:28)

The image shows a whiteboard with handwritten mathematical equations. The top equation is $\tilde{y} = \sum V^H \bar{x} + \tilde{n}$. The second equation is $= \sum \underbrace{V^H V}_{I} \tilde{x} + \tilde{n}$. The final equation, enclosed in a box, is $\Rightarrow \tilde{y} = \sum \tilde{x} + \tilde{n}$. The whiteboard interface includes a menu bar (File, Edit, View, Insert, Actions, Tools, Help), a toolbar with drawing tools, and a status bar at the bottom showing '311 / 425'.

Now, you substitute this in our model that we have over here, that is, you have \tilde{y} equals $\sum V^H \bar{x} + \tilde{n}$. You substitute the model, the pre-coding model, that is, $V^H V \tilde{x} + \tilde{n}$ and $V^H V$ is Identity, so this gives us, this implies, we are left with the model, this reduces to \tilde{y} equals to $\sum \tilde{x} + \tilde{n}$. And this is very interesting. Why is this interesting?

(Refer Slide Time: 18:12)

$$y = \sum V x + n$$
$$= \sum \underbrace{V^H V}_I \tilde{x} + \tilde{n}$$
$$\Rightarrow \tilde{y} = \sum \tilde{x} + \tilde{n}$$

Diagonal matrix

$$= \begin{bmatrix} \sigma_1 & 0 & \dots & 0 \\ 0 & \sigma_2 & \dots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \dots & \dots & \sigma_t \end{bmatrix}$$

This is interesting because this matrix Sigma, this is a diagonal matrix which comprises of the entries Sigma1, Sigma2, this is a diagonal matrix.

(Refer Slide Time: 18:37)

$$\begin{bmatrix} \tilde{y}_1 \\ \tilde{y}_2 \\ \vdots \\ \tilde{y}_k \end{bmatrix} = \begin{bmatrix} \sigma_1 & & & \\ & \sigma_2 & & \\ & & \dots & \\ & & & \sigma_t \end{bmatrix} \begin{bmatrix} \tilde{x}_1 \\ \tilde{x}_2 \\ \vdots \\ \tilde{x}_k \end{bmatrix} + \begin{bmatrix} \tilde{n}_1 \\ \tilde{n}_2 \\ \vdots \\ \tilde{n}_k \end{bmatrix}$$

Decoupled System!

$$\begin{aligned} \tilde{y}_1 &= \sigma_1 \tilde{x}_1 + \tilde{n}_1 \\ \tilde{y}_2 &= \sigma_2 \tilde{x}_2 + \tilde{n}_2 \\ &\vdots \\ \tilde{y}_k &= \sigma_k \tilde{x}_k + \tilde{n}_k \end{aligned}$$

Handwritten notes on a digital whiteboard showing a decoupled system model. The equations are:

$$\begin{aligned} \tilde{y}_1 &= \sigma_1 \tilde{x}_1 + \tilde{n}_1 \\ \tilde{y}_2 &= \sigma_2 \tilde{x}_2 + \tilde{n}_2 \\ &\vdots \\ \tilde{y}_t &= \sigma_t \tilde{x}_t + \tilde{n}_t \end{aligned}$$

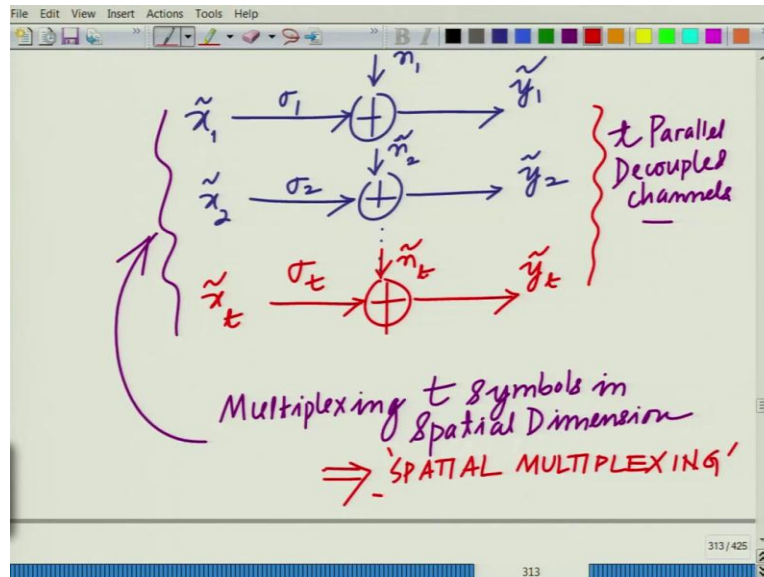

A blue bracket on the left labels it "Decoupled System!". A red note on the right says "Because each \tilde{y}_i depends only on \tilde{x}_i ". Handwritten labels at the top identify \tilde{y} , Σ , \tilde{x} , and \tilde{n} .

In fact, if you expand this model, you can write this as follows. That is, you have y_1 tilde, y_2 tilde, so on, y_t tilde equals $\sigma_1, \sigma_2, \sigma_t$ times x_1, x_2, x_t plus n_1, n_2, n_t . So this is your MIMO system model. And interestingly if you write, I'm sorry, this is x_1 tilde, x_2 tilde, x_3 tilde. And now, if you write these things and these are n_1 tilde, n_2 tilde, n_t tilde.

And now, if write these things (explicitly), so this is your matrix y tilde, this is the diagonal matrix Σ , this is your x tilde and this is your n tilde. And if you write these equations explicitly, then what you obtain is that y_1 tilde equals $\sigma_1 x_1$ tilde plus n_1 tilde. y_2 tilde equals $\sigma_2 x_2$ tilde plus n_2 tilde, so on, and you will get y_t tilde equals $\sigma_t x_t$ tilde plus n_t tilde and therefore you can see, this is essentially a decoupled system.

Why is this a decoupled system? Because you can see each y_i depends only, each y_i tilde depends only on x_i tilde. that is, y_1 tilde depends on x_1 tilde, y_2 tilde depends on x_2 tilde, so on and so forth, y_t tilde depends only on x_t tilde. So this is a decoupled system because each y tilde depends only on x_i tilde.

(Refer Slide Time: 21:28)

And if you represent this using a diagram, you will find that this is essentially, you have, x_1 tilde, multiply this by σ_1 , add the noise, you have n_1 tilde, add n_1 tilde, you get y_1 tilde, x_2 tilde, you add the noise, n_2 tilde, multiply by σ_2 x_2 tilde, this gives y_2 tilde, so on and so forth. Finally, you have n_t tilde, you have σ_t and you have x_t tilde and this gives y_t tilde. And therefore, what you can see is, essentially you have, essentially this reduces to a set of t parallel decoupled channels. This reduces to a set of t parallel decoupled channels.

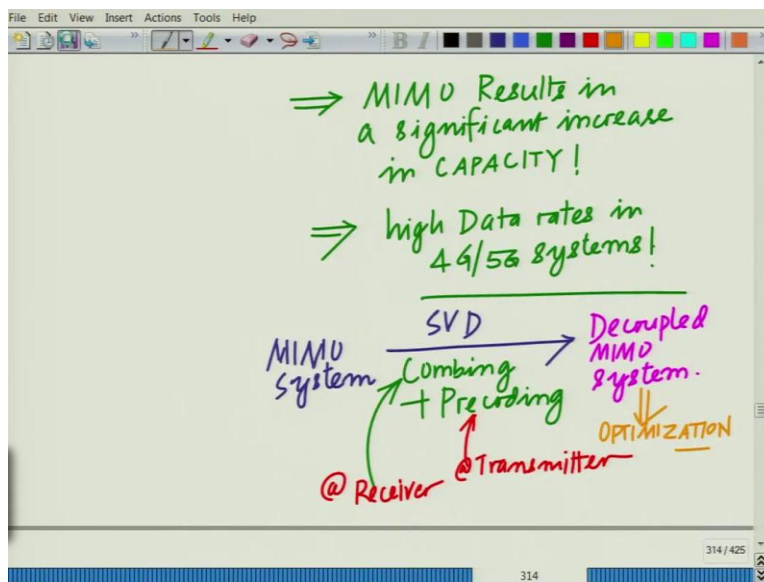

And therefore, now, you can see is that the MIMO system, if you think of a MIMO system, the MIMO system, r cross t MIMO system, r greater than equal to t , essentially can be decoupled into a set of t independent parallel channels in which, in each channel you are transmitting the symbol x_i tilde. It is acted upon by the gain σ_i and then of course the noise n_i tilde and then you get the output, y_i tilde.

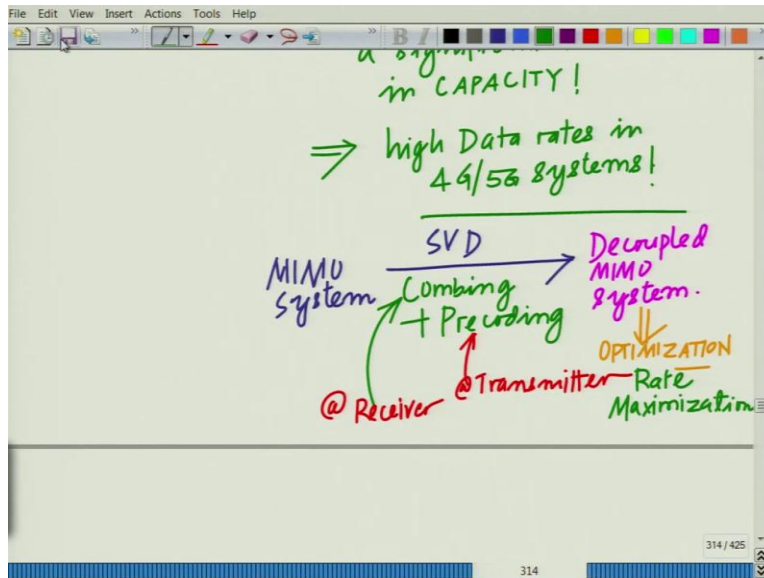

And you have t such channels. So it is a collection or a bundling together or t such channels. And you are multiplexing these symbols, they are multiplexing these symbols, x_1 tilde, x_2 tilde, x_3 tilde, same time, same frequency in the spatial dimension. Spatial dimension, by that we mean the antennas and therefore this is known as Spatial Multiplexing.

So this property of the MIMO system essentially, where you are multiplexing these multiple symbols, so you are multiplexing t symbols in the spatial dimension and this is essentially what is termed as Spatial Multiplexing. So you are multiplexing, so what the MIMO system is allowing you to do is to the same time, same frequency, it is allowing you to increase the capacity by a factor of t , that is essentially a minimum of r comma t .

So the capacity increases by a factor of t or the rate increases by a factor of t because you are able to multiplex these t symbols spatially, in the using, in leveraging the spatial dimension which is not, by the way, exploited when you have single transmit and single input antenna. So this is something which is unique to MIMO system. So MIMO system results in a t fold increase in a capacity.

(Refer Slide Time: 25:34)

So this implies, because of Spatial Multiplexing, this implies MIMO, and this is what leads to high data rates in 4G, 5G systems. That is, you have, of course, you have a large bandwidth but in addition, you can also, one can also exploit the spatial dimension to transmit or multiplex multiple symbols for the same time and frequency resource.

And therefore, essentially, what this singular value decomposition is doing, is essentially, the singular value decomposition is giving you a technique to convert, so what does this singular, SVD do? SVD is giving you a technique to convert this coupled MIMO system with the interference between the symbols, that is, your x_1 , x_2 , x_3 , and these symbols are interfering as we have seen earlier. So SVD is a very interesting and effective tool to take this coupled MIMO system with interference and go to a decoupled MIMO system via pre-coding at the transmitter and combining at the receiver.

So what we have, essentially, is, you have the MIMO system. We have performed the SVD which is basically your combining plus pre-coding. The combining is at the transmitter, the pre-coding, so the combining is being performed at the transmitter, I am sorry, combining is being performed at the receiver and the pre-coding is being performed at the transmitter. And the SVD gives you, what it gives you is, essentially, it gives you the decoupled. And this can now be optimized as we shall see in the next module.

How can this decoupled MIMO system makes it easier for optimization, processing and so on. So one can use this decoupled MIMO system for optimization. What do we mean by optimization? We can use it for rate maximization, to maximize the transmit rate. I can use this for rate maximization, which is what we will look at in the subsequent module. So, as we have seen SVD has significant practical implications.

One of the most important practical implications, we can say, is to take this MIMO system, convert it from a coupled MIMO system to a decoupled MIMO system and then use it for further optimization and then that in turn, because of the Spatial Multiplexing property of MIMO, where you can transmit several symbols in parallel over the same time, frequency resource, that leads to a significant high, significantly high throughput in 4G and 5G wireless systems. So let us stop here and continue in the subsequent modules. Thank you very much.
