LMMSE Estimate and Error Covariance Matrix

(Refer Slide Time: 00:42)

The image shows a handwritten derivation on a whiteboard. At the top left, it is labeled "#36". The main title is "LMMSE:". Below this, the expression for the error covariance matrix is given as the trace of a matrix. The matrix is derived from the expectation of the squared norm of the estimation error, $E\{\|\bar{x} - \hat{x}\|^2\}$, where $\hat{x} = C\bar{y}$. The derivation shows the expansion of this expression into a trace of a matrix with terms R_{xx} , $-CR_{yx}$, $-R_{xy}C^T$, $+CR_{yy}C^T$, $+R_{xy}R_{yy}^{-1}R_{yx}$, and $-R_{xy}R_{yy}^{-1}R_{yx}$. A blue bracket on the right side of the matrix is labeled "Adding Subtracting".

$$E\{\|\bar{x} - \hat{x}\|^2\} = \text{Tr} \left\{ \begin{array}{l} R_{xx} - CR_{yx} - R_{xy}C^T \\ + CR_{yy}C^T \\ + R_{xy}R_{yy}^{-1}R_{yx} \\ - R_{xy}R_{yy}^{-1}R_{yx} \end{array} \right\}$$

Hello, welcome to another module in this massive open online course. So, we are discussing about the LMMSE estimator that is the linear minimum mean squared error estimator that is given a quantity \bar{y} how to estimate how to find the best linear estimate of another correlated vector \bar{x} such that the mean squared error is minimized, so, that is the LMMSE principle, which as I have already told you has several applications in the context of estimation, so we are talking about the LMMSE estimator.

And what we have shown so far is that I have norm of expected value of norm of \bar{x} minus \hat{x} whole square where \hat{x} remember this is a linear estimator, this is of the form $C\bar{y}$, this can be expressed as, well this can be expressed as a trace of our $\bar{x}\bar{x}$ minus trace of R_{xx} minus $C\bar{y}\bar{x}$ minus $R_{xy}zC^T$ plus $CR_{yy}C^T$ and to this what we are doing is we are adding and subtracting this quantity plus $R_{xy}R_{yy}^{-1}R_{yx}$ minus $R_{xy}R_{yy}^{-1}R_{yx}$. So, we are adding and subtracting this quantity essentially, and it minimizes the trace of this whole quantity, so adding and subtracting, so adding or subtracting this quantity.

(Refer Slide Time: 2:53)

$$= \min \text{Tr} \left\{ (C R_{yy} - R_{xy}) R_{yy}^{-1} (C R_{yy} - R_{xy})^T + R_{xx} - R_{xy} R_{yy}^{-1} R_{yx} \right\}$$

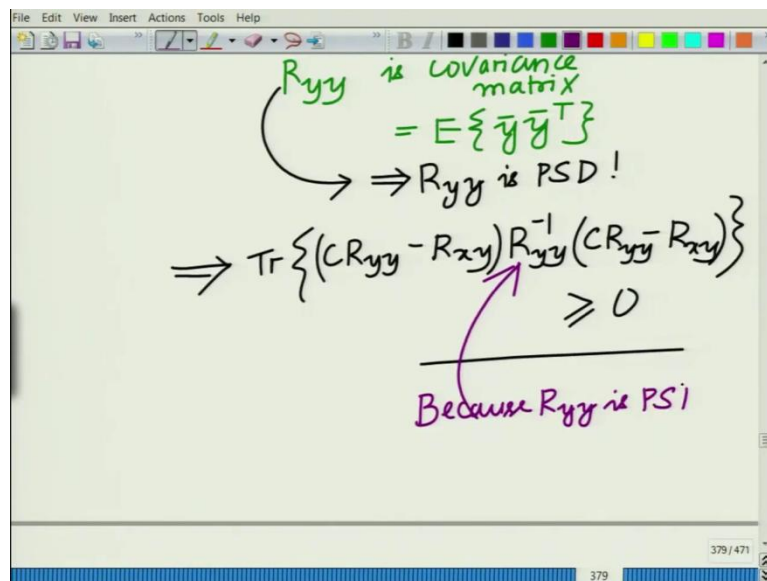

Constant i.e. Does NOT depend on C

$$\Rightarrow \min \text{Tr} \left\{ (C R_{yy} - R_{xy}) R_{yy}^{-1} (C R_{yy} - R_{xy})^T + R_{xx} - R_{xy} R_{yy}^{-1} R_{yx} \right\}$$

And therefore, now if we want to minimize this, that becomes equivalent to minimizing this quantity that we have just written over here. And this you can see essentially, if you examine this deeply, what we are trying to do is essentially we are trying to complete the square over here as you are going to see and you can write this you can check this, this can be written in a very nice compact form as minimize trace $C R_{yy} - R_{xy}$ into $R_{yy}^{-1} C R_{yy} - R_{xy}$ transpose plus $R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$. So, this can be simplified in this fashion and now you can see that this quantity here if you look at this quantity, this is a constant in the sense that does not depend on C .

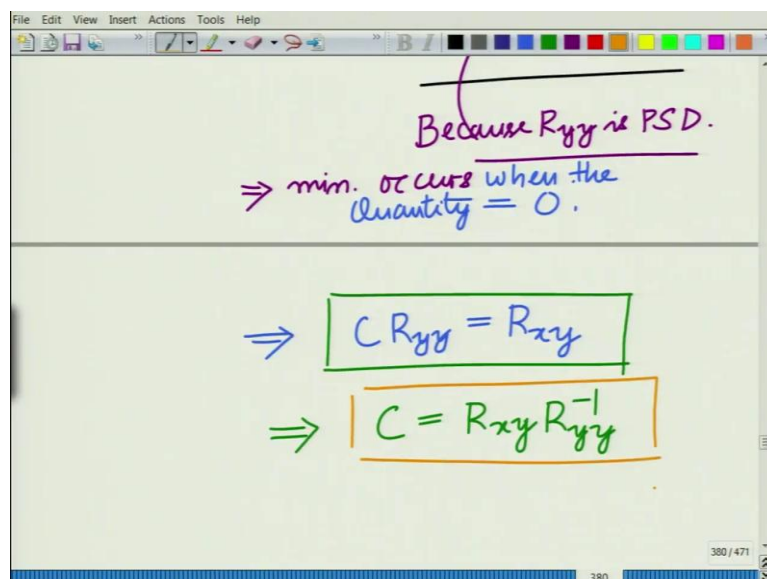

Remember we are trying to find the best C that minimizes the mean square error, constant that is does not this does not depends on C , implies I can write this as minimize trace of $C R_{yy} - R_{xy}$ times $R_{yy}^{-1} C R_{yy} - R_{xy}$ transpose plus $R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$ which is a constant. So, this comes out of the minimization and you are left with this first step essentially, because the second term is essentially a constant that does not depend on the matrix C .

(Refer Slide Time: 6:19)

And now, if you look at this to minimize this quantity, note that this quantity if you look at this this R_{yy} inverse this is interesting because R_{yy} remember R_{yy} is a covariance matrix. This is basically if you remember, this is basically expected $\bar{y}\bar{y}^T$. So this essentially implies that remember any (posi) covariance matrix is positive semi definite, this implies that R_{yy} . So, this implies that R_{yy} is a positive semi definite matrix, this implies that this quantity that is trace of $C R_{yy}$ minus R_{xy} into R_{yy} inverse $C R_{yy}$ minus R_{xy} , this quantity is always greater than or equal to 0 because R_{yy} is PSD

(Refer Slide Time: 7:54)

Implies minimum implies minimum of this occurs for above occurs when the quantity equal to 0, when the quantity is equal to 0, that is obvious because it is always greater than equal to

0 so the minimum value of this is naturally this is equal to C. And therefore, now for this to be minimum that occurs when does the minimum occur, if you remember it is a positive semi definite matrix minimum occurs only when $C R y y$ equals implies $C R y y$ equals $R x y$ which essentially implies that C equals $R x y$ times $R y y$ inverse implies C equals $R x y$ into $R y y$ inverse.

(Refer Slide Time: 9:12)

Handwritten mathematical derivation on a whiteboard:

$$\Rightarrow C = R_{xy} R_{yy}^{-1}$$

$$\Rightarrow \hat{x} = C \bar{y}$$

$$\Rightarrow \hat{x} = R_{xy} R_{yy}^{-1} \bar{y}$$

LMMSE
Linear Minimum Mean Square
Error Estimate of \bar{x}

And therefore, this implies now that \hat{x} equal to $C \bar{y}$ which implies \hat{x} the best that is the linear minimum mean squared error estimate of \bar{x} is $R x y R y y$ inverse into \bar{y} . This is the LMMSE estimator. So, it is very simple. It is a very simple structure, this is the LMMSE that is again linear Linear minimum mean squared error estimate of \bar{x} . So that is the LMMSE estimate of \bar{x} .

(Refer Slide Time: 10:33)

$$+ R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$$
 Constant i.e. Does NOT depend on C

$$\Rightarrow \min. \text{Tr} \left\{ (C R_{yy} - R_{xy}) R_{yy}^{-1} (C R_{yy} - R_{xy})^T \right\}$$

$$+ R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$$

R_{yy} is covariance matrix
 $= E \xi \xi^T$?

And what is the minimum error corresponding to this? The minimum error corresponding to this if you look at this remember the first term is reduced to 0 if you take a look at this, the first term this term can be reduced to 0, this term reduces to 0 implies error equal to the second term.

(Refer Slide Time: 11:01)

LMMSE
 Linear Minimum Mean Square
 Error Estimate of \hat{x}

Minimum MSE

$$= \text{Tr} \left\{ R_{xx} - R_{xy} R_{yy}^{-1} R_{yx} \right\}$$

Error covariance matrix

So, therefore, the minimum error if you very easy to deduce the minimum MSE becomes trace of trace of $R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$ this is the minimum MSC and in fact if you look at this, this is nothing but the error covariance matrix, matrix for the LMMSE.

(Refer Slide Time: 12:06)

The image shows a whiteboard with the following handwritten text:

$$E\{(\bar{x} - \hat{x})(\bar{x} - \hat{x})^T\}$$
$$= R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$$

LMMSE Error Covariance.

That is if you ask the question what is the expected value of \bar{x} minus \hat{x} into \bar{x} minus \hat{x} transpose that is going to be given as R_{xx} that is essentially what the error covariance is that is your R_{xx} minus R_{xy} times R_{yy} inverse into R_{yx} so this is your LMMSE error covariance matrix, this is the LMMSE error covariance. And so that is essentially that answers both the questions, what is LMMSE of estimator of \bar{x} in terms of the correlated vector \bar{y} and what is the what is the covariance error covariance of the LMMSE estimator.

(Refer Slide Time: 13:27)

The image shows a whiteboard with the following handwritten text:

\bar{x}, \bar{y} , NOT zero mean.

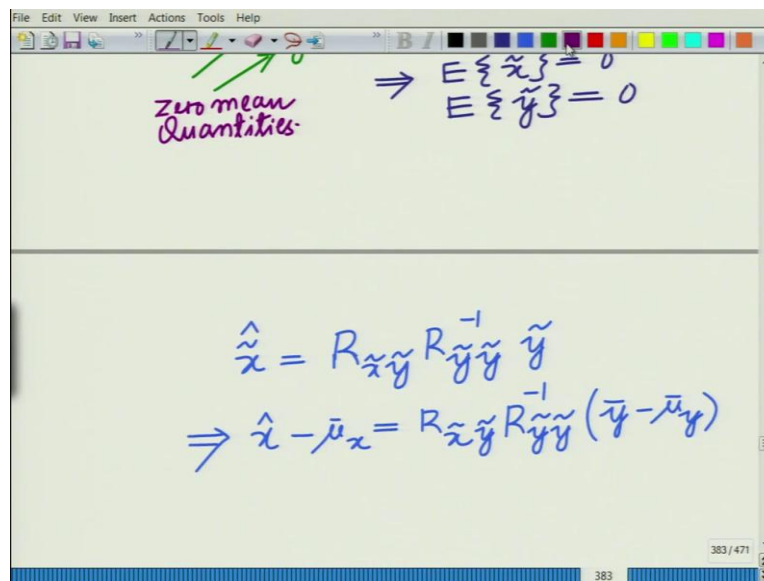

$$\Rightarrow E\{\bar{x}\} = \bar{\mu}_x$$
$$E\{\bar{y}\} = \bar{\mu}_y$$
$$\tilde{x} = \bar{x} - \bar{\mu}_x$$
$$\tilde{y} = \bar{y} - \bar{\mu}_y$$

zero mean quantities.

And now, let us look at the other case that is generalized this when \bar{x} comma \bar{y} are not, when \bar{x} \bar{y} are not 0 mean this implies that you have expected value of \bar{x} is

equal to 0, expected value of y I am sorry expected value of x x bar equal to Mu bar x which is not necessarily 0, this is Mu bar y not necessarily 0. Now, what we do is very simple, you subtract the mean for the 0 mean quantities x bar minus Mu x bar form y tilde equals y bar minus Mu bar y. Now, note that these are 0 mean quantities now you have subtracted the mean so you have got, these are 0 mean quantities.

(Refer Slide Time: 14:51)

zero mean quantities $\Rightarrow E\{\tilde{x}\} = 0$
 $E\{\tilde{y}\} = 0$

$$\hat{\tilde{x}} = R_{\tilde{x}\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} \tilde{y}$$

$$\Rightarrow \hat{x} - \bar{\mu}_x = R_{\tilde{x}\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} (\bar{y} - \bar{\mu}_y)$$

Essentially we have expected value of x tilde equal to 0 and expected value or y tilde equal to 0. So, we can use our we can use our LMMSE estimator that we have just been derived for the 0 mean quantities. And therefore, I can write the estimate of x tilde hat, this is going to be R x tilde y tilde times R y tilde y tilde inverse times y bar, which is nothing but remember now, writing this as x hat minus Mu bar x equal to R x tilde y tilde, sorry this will also be y tilde, R y tilde y tilde inverse times y bar minus Mu bar y.

(Refer Slide Time: 16:14)

$$\Rightarrow \hat{x} - \bar{\mu}_x = R_{\tilde{x}\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} (\bar{y} - \bar{\mu}_y)$$
$$\Rightarrow \hat{x} = R_{\tilde{x}\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} (\bar{y} - \bar{\mu}_y)$$
$$R_{\tilde{y}\tilde{y}} = E \{ \tilde{y} \tilde{y}^T \}$$
$$= E \{ (\bar{y} - \bar{\mu}_y) (\bar{y} - \bar{\mu}_y)^T \}$$
$$= R_{yy}$$

This implies that \hat{x} equals $R_{\tilde{x}\tilde{y}}$ times $R_{\tilde{y}\tilde{y}}^{-1}$ times $\bar{y} - \bar{\mu}_y$. Now let us ask the question what are these quantities $R_{\tilde{x}\tilde{y}}$, $R_{\tilde{y}\tilde{y}}$ and $R_{\tilde{x}\tilde{y}}$, there is a covariance matrix of \tilde{y} and the cross covariance between \tilde{x} and \tilde{y} .

And it is very easy to see that these quantities are nothing but $R_{\tilde{y}\tilde{y}}$ equals expected value of $\tilde{y} \tilde{y}^T$ which is nothing but expected value of $\bar{y} - \bar{\mu}_y$ into $\bar{y} - \bar{\mu}_y$ transpose which is nothing but R_{yy} , covariance matrix of \bar{y} .

(Refer Slide Time: 17:26)

$$R_{\tilde{x}\tilde{y}} = E \{ \tilde{x} \tilde{y}^T \}$$
$$= E \{ (\bar{x} - \bar{\mu}_x) (\bar{y} - \bar{\mu}_y)^T \}$$
$$= R_{xy}$$

Similarly, $R_{x\tilde{y}}$ is equal to the expected value of \tilde{x} minus or expected value of \bar{x} , this is expected value of \tilde{y} transpose which is nothing but expected value of \bar{y} minus $\bar{\mu}_y$ into \bar{y} minus $\bar{\mu}_y$ transpose which is equal to R_{xy} . So, we have $R_{x\tilde{y}}$ equal to R_{xy} and therefore finally, we can write this implies that we have a very simple expression for the LMMSE estimator \hat{x} equals $R_{xy} R_{yy}^{-1} \bar{y}$ minus $\bar{\mu}_y$ correct.

(Refer Slide Time: 18:46)

$$\hat{x} = R_{x\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} \tilde{y}$$

$$\Rightarrow \hat{x} - \bar{\mu}_x = R_{x\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} (\bar{y} - \bar{\mu}_y)$$

$$\Rightarrow \hat{x} = R_{x\tilde{y}} R_{\tilde{y}\tilde{y}}^{-1} (\bar{y} - \bar{\mu}_y) + \bar{\mu}_x$$

$$R_{\tilde{y}\tilde{y}} = E\{\tilde{y}\tilde{y}^T\}$$

$$= E\{(\bar{y} - \bar{\mu}_y)(\bar{y} - \bar{\mu}_y)^T\}$$

$$= R_{yy}$$

I am sorry here you have to have $\bar{\mu}_x$ that comes from the left $\bar{\mu}_x$.

(Refer Slide Time: 18:57)

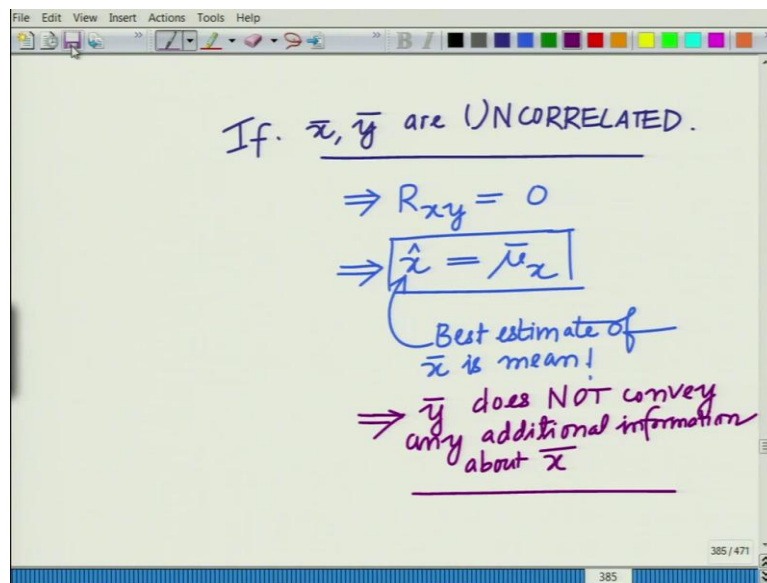

$$= R_{xy}$$

$$\Rightarrow \hat{x} = R_{xy} R_{yy}^{-1} (\bar{y} - \bar{\mu}_y) + \bar{\mu}_x$$

LMMSE Estimate

So, therefore, you have plus, you have this is essentially the expression that one obtains for the LMMSE estimate, once again this is the LMMSE estimate of, once again this is basically your LMMSE, this is basically your LMMSE estimate in terms of the this thing. So that essentially completes our derivation of the LMMSE estimate both for of course, first for the 0 mean quantities \bar{x} and \bar{y} and where the quantities are general that is the mean is not equal to the sum. And you can in fact observe something very interesting. So, what happens here is if \bar{x} and \bar{y} are uncorrelated.

(Refer Slide Time: 20:06)

Now, let us look at an interesting case, if \bar{x} and \bar{y} are uncorrelated. Now, this implies that this implies that R_{xy} equal to 0, if you look at this if R_{xy} equal to 0, \hat{x} is simply equal to $\bar{\mu}_x$. So this implies very interestingly, if you look at this, this implies \hat{x} equals $\bar{\mu}_x$ that is it, very interestingly \hat{x} reduces to $\bar{\mu}_x$ that is the best estimate of \bar{x} is simply the mean because \bar{y} does not convey any additional information about \bar{x} because the cross correlation R_{xy} equals 0. So, this also implies that \bar{y} , observing \bar{y} does not convey any additional, \bar{y} does not convey any additional information about \bar{x} .

So, therefore, the best way is to observe \bar{y} your knowledge about \bar{x} or your estimate of \bar{x} does not change and the estimate of \bar{x} is simply the mean that is $\bar{\mu}_x$, which you had set anyway, if there were no there was no observation to begin with. So, if you have a random vector, and there are no observations, and if someone asks you what is the best estimate that you can or the best prediction that you can make of a random quantity, without

any observation is essentially that the best estimate would be the mean of that random quantity.

Now, because \bar{x} and having observed \bar{y} if \bar{x} and \bar{y} are correlated, you would expect to make a better guess or a better estimate of \bar{x} , but unfortunately if \bar{x} and \bar{y} are uncorrelated, observation of \bar{y} does not help and the best estimate of \bar{x} is still the mean, which also goes to show that the better the correlation the stronger the correlation between \bar{x} and \bar{y} the better is your estimate of \bar{x} going to be and that is in fact, if you look at this expression, that is in fact reflected in the error covariance.

(Refer Slide Time: 23:19)

Handwritten mathematical derivation of LMMSE Error Covariance matrix:

$$E\{(\bar{x} - \hat{x})(\bar{x} - \hat{x})^T\} = R_{xx} - R_{xy} R_{yy}^{-1} R_{yx}$$

Annotations:

- Green arrow: Error covariance matrix
- Purple arrow: Greater $R_{xy} \Rightarrow$ Lower Error!
- Orange arrow: LMMSE Error Covariance

\bar{x}, \bar{y} , NOT zero mean.

If you examine this again you will notice that this error covariance is R_{xx} minus $R_{xy} R_{yy}^{-1} R_{yx}$ inverse implies this implies greater R_{xy} , greater the cross correlation of course, these are matrices So, you cannot say one is greater one is lesser but intuitively greater R_{xy} implies more error.

So, what you can see is that if R_{xy} if the correlation is strong, the resulting error will be lower because your prediction of \bar{x} is much better. So, these are essentially the very interesting things that followed from analyzing this LMMSE estimator and the LMMSE estimation principle in general. So, let us stop this discussion here and we will continue in the subsequent modules. Thank you very much.
