**Time-series Prediction via auto-regression (AR) model**

Hello, welcome to another module in this massive open online course. So, let us continue our discussion on optimal estimation and let us look at another interesting extension of this and this is to the concept of, what we call a self prediction or what essentially auto-regression.

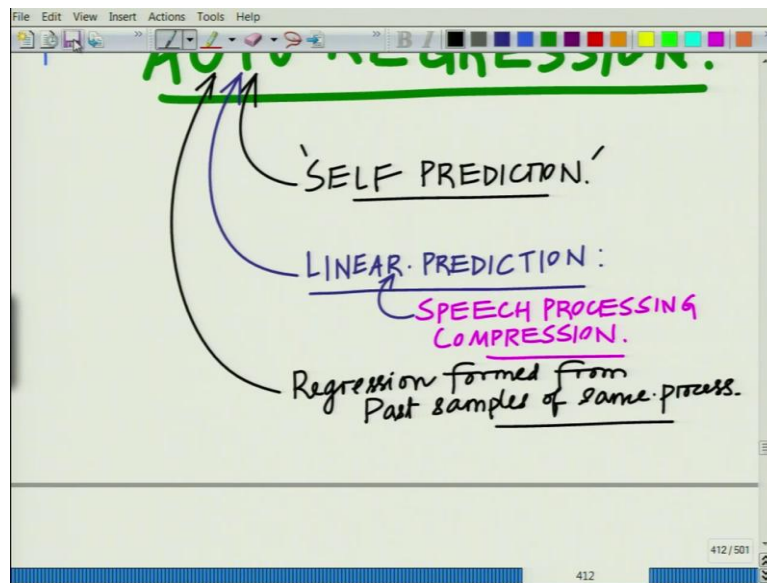

(Refer Slide Time: 00:35)

So, I am going to explain more about this, what we want to discuss or talk about is essentially the concept of auto-regression as you are familiar regression essentially is prediction. So, auto-regression, auto is essentially self prediction using the quantities in fact the past values of the quantities as we are going to see, this auto means the self itself and regression is essentially prediction or approximation and this belongs to an important class of techniques that is essentially your linear prediction so, this essentially is based on the theory of linear prediction or linear estimation.

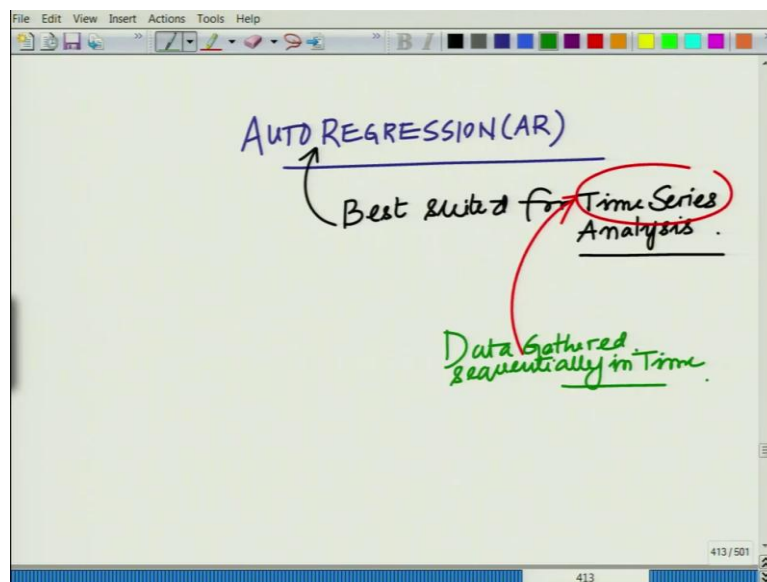

Which is essentially also used in linear predictive coding, which is again used in speech processing and so on so, there are many applications for this which, processing is also used in for instance compression so on and so forth so, what is auto regression?

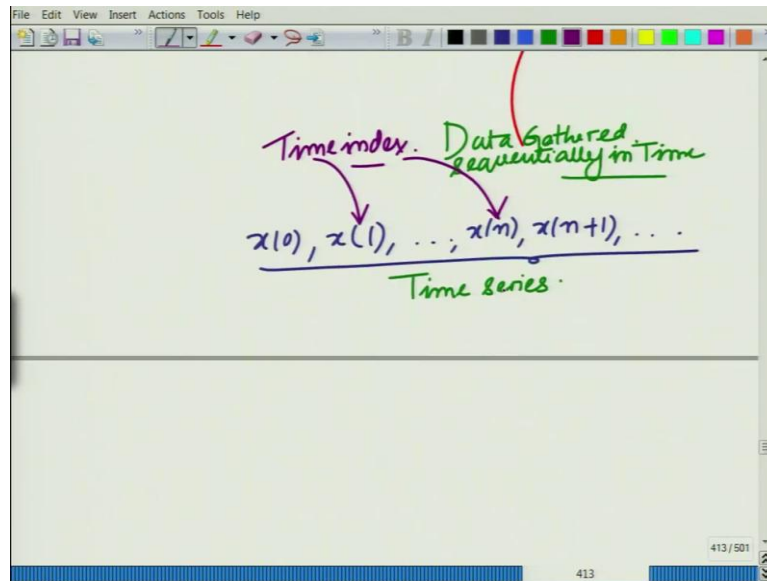

(Refer Slide Time: 02:16)

As I have already said auto-regression is essentially the regression formed from the past sample of same process and where you see this most often is in the context of a time-series that is data gathered sequentially in time those linear prediction is best suited for a time-series or the analysis of time-series.

(Refer Slide Time: 03:05)

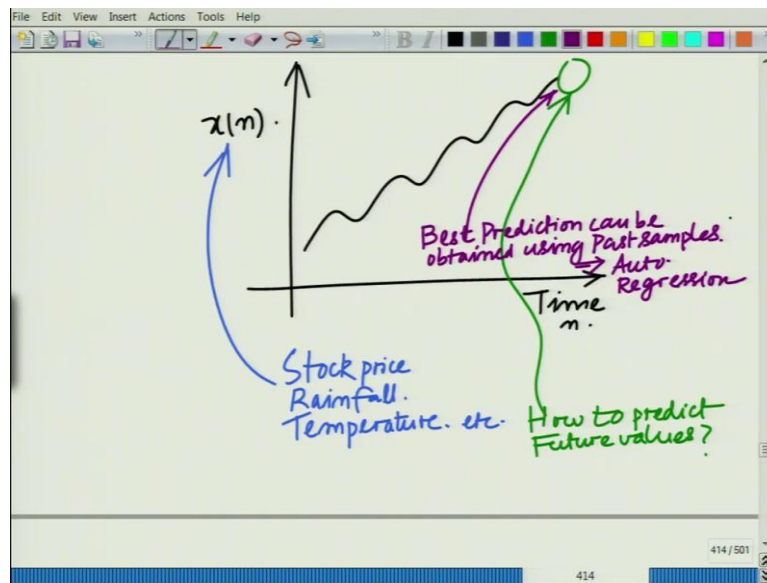

So, auto-regression what, we call as AR auto-regression this is best suited for time-series analysis and what is time-series?

This time-series is nothing but, data gathered sequentially in time, so time-series is basically data that is gathered sequential in time for instance you have the data  $x_0, x_1, x_n$ , so on and so forth, so this forms your time-series and this is your time index and this for instance this  $n$ , this is essentially the time index.

And, so you have time-series and essentially regression that is formed using the past samples of this time-series, that is essentially auto-regression that is prediction using the past samples where is this useful?

(Refer Slide Time: 05:18)

Now, this time-series typically occurs many places such as for instance you have some quantity that is varying with respect to time and this is your  $x$  of  $n$  and this can arise for instance in your stock price or the amount of rainfall or parameters such as, temperature, etc.

So, these that is when you measure these things, that is the stock price day after day, when you tabulate the stock prices list the stock prices day after day as a series day 0, day 1, day 2 so on so, that becomes a time-series similarly, the amount of rainfall the temperature on a particular day.

So, it occurs very, very frequently that is wherever you are taking samples of the quantity in time. And naturally the question that we are interested in is at this point, if you are at this is the current point, how to predict the future values of the time-series the point is you might have already guessed the best prediction of the future can be obtained using the past samples or the immediate past samples and that is essentially what we would like to regress on that is regress on the past samples and that makes it the auto-regression. So, the best prediction can be obtained using past samples, this implies auto-regression. So, what is auto regression?

(Refer Slide Time: 07:54)

The image shows a handwritten slide with the following content:

$$\hat{x}(n) = a_1 x(n-1) + a_2 x(n-2) + \dots + a_L x(n-L)$$

Annotations on the slide:

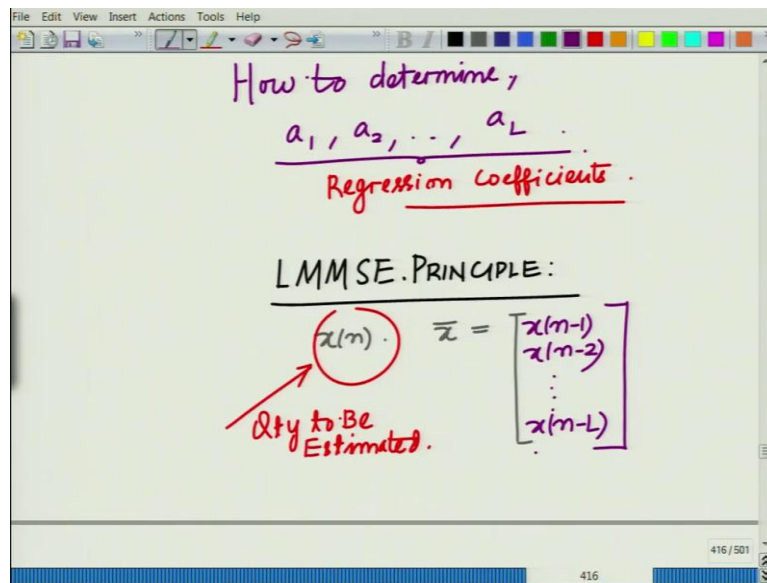

- A blue arrow points from the text "Form: Best estimate of  $x(n)$ ." to the circled  $\hat{x}(n)$  in the equation.
- Green text: "Regress using past samples of same process." with arrows pointing to the terms  $a_1 x(n-1)$  and  $a_2 x(n-2)$ .
- Pink text: "L past samples.  $\Rightarrow$  L<sup>th</sup> order AR model." with an arrow pointing to the term  $a_L x(n-L)$ .
- Blue text: "AR model." with an arrow pointing to the entire equation.

415 / 501

Auto-regression is essentially you form the prediction that is  $\hat{x}(n)$  using the past samples regress based on past samples of the same process. So, this is if you look at this what we are doing is we are regressing, we regress using the past samples of the same process and we form the best estimate of  $x(n)$ , form best, obtain the best estimate of  $x(n)$  and this is essentially your autoregressive model.

And in fact, you are using  $L$  past samples so remember this implies, this becomes  $L^{\text{th}}$  order, so this becomes an  $L^{\text{th}}$  order AR model if you are using 1 past sample like  $x(n) = a_1 x(n-1)$  that mean, that is the first order model and  $a_1 x(n-1) + a_2 x(n-2)$  that becomes a second order AR model we are using  $L$  past samples. That is the  $L^{\text{th}}$  order AR model.

(Refer Slide Time: 10:02)

How to determine,  
 $a_1, a_2, \dots, a_L$   
Regression coefficients.

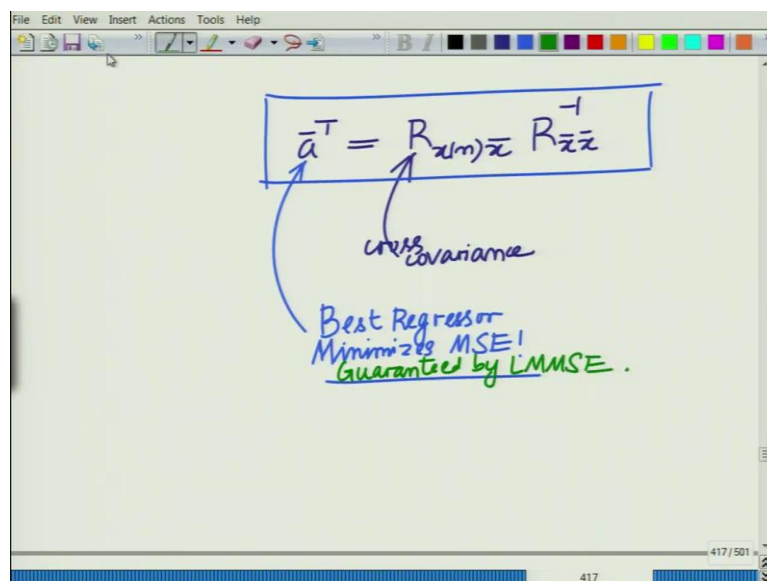

LMMSE PRINCIPLE:

$x(m)$ . Qty to be Estimated.

$\bar{x} = \begin{bmatrix} x(m-1) \\ x(m-2) \\ \vdots \\ x(m-L) \end{bmatrix}$

Now, the idea here is what are the regression coefficients, how to determine which are essentially nothing but the, which are nothing but the regression coefficients and these as we know can be determined by using the LMMSE we once again come back to the LMMSE principle that is, if we call the quantity to be predicted as  $x_n$  and then, we denote by  $\bar{x}$  this is the quantity to be estimated and  $\bar{x}$  these are the known this is  $x_{n-1}$   $x_{n-2}$  so on  $x_{n-L}$ .

(Refer Slide Time: 11:44)

$\bar{a}^T = R_{x(m)\bar{x}} R_{\bar{x}\bar{x}}^{-1}$

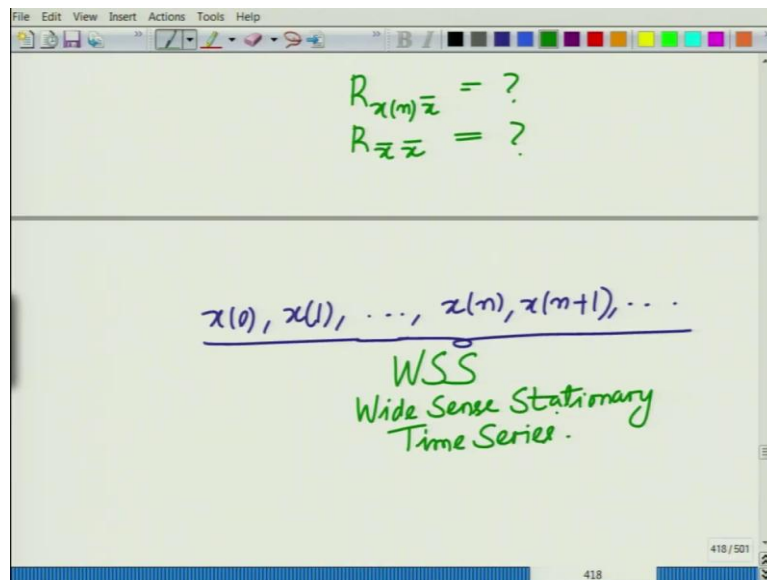

cross covariance

Best Regressor  
Minimizes MSE!  
Guaranteed by LMMSE.

Then, the optimal regressor as we know, is given a bar transpose this is the cross covariance of  $x_n$  bar  $\bar{x}$  so this is the cross covariance times  $R_{\bar{x}\bar{x}}^{-1}$  this is your optimal

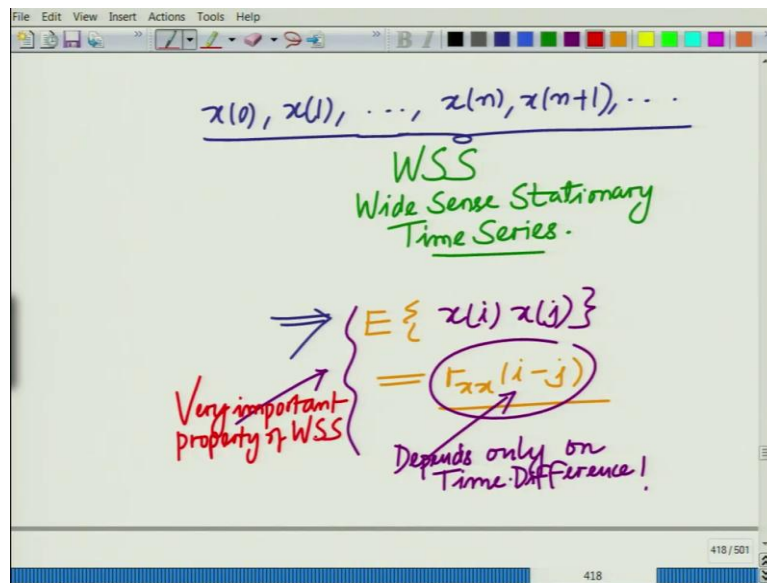

regressor, this is the best regressor that minimises the mean squared error, this minimises the MSE and we know that from the LMMSE principle, so that is we want to predict or if you want to estimate  $\bar{x}$  then the optimal regressor is  $R_{xy} R_{yy}^{-1}$  and this is basically guaranteed by the LMMSE principle.

(Refer Slide Time: 13:13)

Now, let us look at these quantities the question that we want to ask is what are these quantities  $R_{x \bar{x}}$  and what are these quantities  $R_{\bar{x} \bar{x}}$  and for that we will need some property on this time-series  $x_0, x_1, x_{n+1}$  so on, we will assume that this is what is known as a WSS that is wide, this is a wide sense stationary time series that is we will assume this is a wide sense stationary time series.

(Refer Slide Time: 14:24)

Which essentially implies that if you look at the correlation that is  $x$  of  $n$  minus  $i$  times  $x$  of  $n$  minus  $j$  this only depend on  $i$  minus  $j$  that is the lag between these two samples this is an important property of wide sense stationary time-series that is if you look at auto correlation between two different samples  $x$  of  $n$  minus  $i$  into  $x$  of  $j$  or you can also write it as  $x$  of  $i$  times probably it is better to write it this way  $x$  of  $i$  times  $x$  of  $j$  this is simply  $x$  of  $i$  minus  $j$  depends only on the lag, on the time difference, depends only on the time difference between those two is two samples that is we will get two samples  $x$  of  $n$  and  $x$  of  $m$ , ask what is the correlation?

The correlation is  $R_{xx}(n$  minus  $m$  it does not depend on  $n$  and  $m$  but only the rather that difference  $n$  minus  $m$  so this is essentially a very important property a characteristic, a very important property of WSS, very important property of wide sense stationary random process.

(Refer Slide Time: 16:19)

Time Difference!

$$R_{\bar{x}\bar{x}} = E \{ \bar{x} \bar{x}^T \}$$

$$= E \left\{ \begin{bmatrix} x^{(n-1)} \\ x^{(n-2)} \\ \vdots \\ x^{(n-l)} \end{bmatrix} \begin{bmatrix} x^{(n-1)} & \dots & x^{(n-l)} \end{bmatrix} \right\}$$

$$= E \left\{ \begin{bmatrix} x^2(n-1) & x(n-1)x(n-2) & \dots \\ x(n-1)x(n-2) & x^2(n-2) & \dots \\ \vdots & \vdots & \ddots \end{bmatrix} \right\}$$

$$= E \left\{ \begin{bmatrix} x^{(n-1)} \\ x^{(n-2)} \\ \vdots \\ x^{(n-l)} \end{bmatrix} \begin{bmatrix} x^{(n-1)} & \dots & x^{(n-l)} \end{bmatrix} \right\}$$

$$= E \left\{ \begin{bmatrix} x^2(n-1) & x(n-1)x(n-2) & \dots \\ x(n-1)x(n-2) & x^2(n-2) & \dots \\ \vdots & \vdots & \ddots \end{bmatrix} \right\}$$

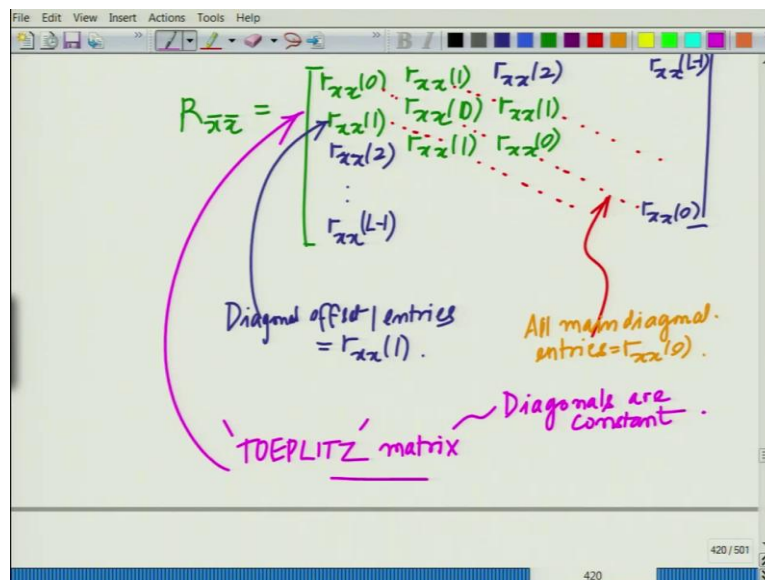

Now, let us ask the question what is  $R_{\bar{x}\bar{x}}$ , this is essentially expected value of  $\bar{x} \bar{x}^T$ , which is expected value of  $x_0, x_1, \dots, x_{n-1}$  times, I am sorry, this has to be  $x_{n-1} x_{n-2} x_{n-3} \dots x_{n-L}$  times the transpose  $x_{n-1} x_{n-2} \dots x_{n-L}$ .

Now, if you expand this and write it you will realise that this becomes expected value of for instance, here you will have  $x^2(n-1) x^2(n-2) x(n-1)x(n-2) \dots$  and so on and interestingly if you look at it you will see all the diagonals expected value of  $x^2(n-1) x^2(n-2)$ , expected value of  $x^2(n-1)$ , expected value is  $R_{xx}(0)$  because, the time difference is 0  $x_{n-1} x_{n-1} \dots x_{n-1}$ .

Similarly, expected value of  $x$  square  $n$  minus 2 expected value will once again be  $R_{xx} 0$  expected value of  $x_n$  minus 1 into  $x_n$  minus 2 time difference is 1 therefore, expected value will be  $R_{xx} 1$ .

So, if you look at it all the diagonals will have similar elements, the main diagonal will be  $R_{xx} 0$ , the diagonal with offset of 1 will be  $R_{xx} 1$ , diagonal with offset of 2 will be  $R_{xx} 2$  and so on. So, for instance expect, if you take the expected operator inside and write this expected value of this and this if you look at the expected value of these quantities for instance, if you look at the expected value of these quantities expected value equals  $R_{xx} 1$  similarly, here the expected value of this quantity equals  $R_{xx} 1$ .

(Refer Slide Time: 19:50)

So, if you look at this because, of the wide sense stationary nature of the random process  $R_x$  bar  $x$  bar will look like all the diagonals will be  $R_{xx} 0$ ,  $R_{xx} 0$  and 1 offset will be  $R_{xx} 1$ ,  $R_{xx} 1$  and this will be  $R_{xx} 1$  and this will be  $R_{xx} 2$  so on this will be  $R_{xx}$  of, if I m not mistaken, this will be  $R_{xx}$  of  $L$  minus 1 so on, so this will be  $R_{xx}$  of 0 this will be  $R_{xx}$  of  $L$  minus 1 and if you look at this, all the diagonal entries if you look at this all, so if you look at this all the diagonal principle diagonal so, all the principle diagonal entries, all at offset of 1 diagonal offset of 1 these are  $R_{xx} 1$  and 0, so this has a banded structure.

So, you will have the diagonal is  $R_{xx} 0$  then the diagonals with or offset the sub diagonals you can see which are offset of 1 sub and super diagonals which are offset of 1 they have  $R_{xx} 1$  the diagonals that are offset of 2 from the main diagonal they  $R_{xx} 2$  and so on and this

matrix is this is a very interesting structure such a matrix is known as a TOEPLITZ matrix so this matrix is known as TOEPLITZ.

So, if you look at  $x x^T$  vector of  $\bar{x} \bar{x}^T$  Hermitian this has a TOEPLITZ matrix each diagonal principal and sub diagonals, diagonals are constant, the diagonals are essentially constant that is if you look at any diagonal all the values on the diagonal are the same.

(Refer Slide Time: 23:30)

$$\begin{aligned}
 R_{x(m)\bar{x}} &= E \left\{ x^{(m)} \bar{x}^T \right\} \\
 &= E \left\{ x^{(m)} [x^{(m-1)} \dots x^{(m-L)}] \right\} \\
 &= [r_{xx}(1) \ r_{xx}(2) \ \dots \ r_{xx}(L)] \\
 \bar{a}^T &= R_{x(m)\bar{x}} \cdot R_{\bar{x}\bar{x}}^{-1} \\
 &= [r_{xx}(1) \ r_{xx}(2) \ \dots \ r_{xx}(L)] \\
 &\quad \times \begin{bmatrix} r_{xx}(0) & r_{xx}(1) & r_{xx}(2) & \dots \\ r_{xx}(1) & r_{xx}(0) & r_{xx}(1) & \dots \\ r_{xx}(2) & r_{xx}(1) & r_{xx}(0) & \dots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}^{-1}
 \end{aligned}$$

$$\begin{aligned}
 &= [r_{xx}(1) \ r_{xx}(2) \ \dots \ r_{xx}(L)] \\
 \bar{a}^T &= R_{x(m)\bar{x}} \cdot R_{\bar{x}\bar{x}}^{-1} \\
 &= [r_{xx}(1) \ r_{xx}(2) \ \dots \ r_{xx}(L)] \\
 &\quad \times \begin{bmatrix} r_{xx}(0) & r_{xx}(1) & r_{xx}(2) & \dots \\ r_{xx}(1) & r_{xx}(0) & r_{xx}(1) & \dots \\ r_{xx}(2) & r_{xx}(1) & r_{xx}(0) & \dots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}^{-1}
 \end{aligned}$$

Optimal Self Regression AR coefficients

And, now we want to find this, the other matrix that is  $R_{xx}$  bar that is expected value of  $x_n x_n^T$  bar transpose, which is expected value of  $x_{n-1}$  so on up to  $x_{n-L}$  and this is equal to your basically your, you can see this is essentially your  $R_{xx} 1 \ R_{xx} 2 \ R_{xx} L$  which implies that your  $\bar{a}$  bar transpose, this is your  $\bar{a}$  bar transpose is  $R_{x(m)\bar{x}}$  times  $R_{\bar{x}\bar{x}}$  inverse,

which is essentially  $R_{xx}^{-1}$  times inverse of this auto correlation matrix which is  $R_{xx}$  all the diagonals are  $R_{xx}(0)$   $R_{xx}(1)$   $R_{xx}(1)$   $R_{xx}(0)$   $R_{xx}(1)$   $R_{xx}(2)$  so on and then you have the inverse of this matrix.

So, this is essentially your optimal self-regressor, optimal self-regression or basically your auto-regression coefficients, which minimise the mean square error. So, these are the best regression coefficients, which minimise the mean squared error hence, can be used for your prediction essentially also your forecasting in the stock market kind of application you would like to forecast the stock price in the next day or the next couple of days and so on and thereby, bet appropriately or thereby investor properly.

So, this is a lot of applications in fact, even coding compression, if you can predict the next values of the signal then, the remnant what is the difference between the prediction and the actual signal, this is what is known as the innovation and then, one can actually compress only the innovation so, there are many applications actually.

(Refer Slide Time: 27:06)

PREDICTION ERROR:  
*Determines Quality of Regressor*

$$\begin{aligned} \sigma_e^2 &= r_{x(m)x(m)} - \underbrace{R_{x(m)\bar{x}} R_{\bar{x}\bar{x}}^{-1} R_{\bar{x}x(m)}} \\ &= r_{xx(0)} - \bar{a}^T \cdot R_{\bar{x}x(m)} \\ &= r_{xx(0)} - \bar{a}^T \begin{bmatrix} r_{xx(1)} \\ r_{xx(2)} \\ \vdots \\ r_{xx(L)} \end{bmatrix} \end{aligned}$$

422 / 501

Regressors

$$\begin{aligned}
 \sigma_e^2 &= r_{x(m)x(m)} - \underbrace{R_{x(m)\bar{x}} R_{\bar{x}\bar{x}}^{-1} R_{\bar{x}x(m)}} \\
 &= r_{xx(0)} - \bar{a}^T \cdot R_{\bar{x}x(m)} \\
 &= r_{xx(0)} - \bar{a}^T \begin{bmatrix} r_{xx(1)} \\ r_{xx(2)} \\ \vdots \\ r_{xx(L)} \end{bmatrix} \\
 \sigma_e^2 &= r_{xx(0)} - a_1 r_{xx(1)} - a_2 r_{xx(2)} \\
 &\quad \dots - a_L r_{xx(L)}
 \end{aligned}$$

And the prediction error now one can ask the question as a scientist it is not just enough to come up with a prediction but it is also important remember to characterise the prediction error because what determines the quality of the prediction is a prediction error because anyone can come up with a predictor.

Now, what determines the quality of the predictor, is the prediction error so therefore you cannot just simply give a predictor but also the predictor and that is the regressor and what is the regression error going to be because that determines the quality and hence that will in turn determine whether this quality or this level or this regressor is acceptable or not because without that one is totally in the dark about what is the nature or what is the quality of the prediction.

So, that is an important, so this determines the quality of the regressor and thanks to the element missy principle, we already know that is your error sigma square this is in this case because, this is a scalar quantity so the prediction the covariance itself will be the variance.

So, this will be  $R_{x(m)x(m)} - R_{x(m)\bar{x}} R_{\bar{x}\bar{x}}^{-1} R_{\bar{x}x(m)}$ , now  $R_{x(m)x(m)}$  this is  $r_{xx(0)}$  minus  $R_{x(m)\bar{x}}$ , now this quantity if you look at this  $R_{x(m)\bar{x}}$  and  $R_{\bar{x}\bar{x}}^{-1}$  this is nothing but, a bar transpose so this a bar transpose  $R_{\bar{x}x(m)}$  that is expected value of  $\bar{x}$  this is  $r_{xx(0)}$  minus a bar transpose expected value of  $\bar{x}$  into  $x_n$  this is  $r_{xx(0)}$   $r_{xx(1)}$   $r_{xx(2)}$  sorry, this is  $r_{xx(1)}$  because the first value is  $x$  minus 1  $r_{xx(2)}$  so on  $r_{xx(L)}$  and therefore, this is essentially given sigma e square regression error is  $r_{xx(0)}$  minus

$a_1 R_{xx} 1$  minus  $a_2 R_{xx} 2$  minus 1 minus  $a_L R_{xx} L$ . And therefore, that completes our auto-regression.

(Refer Slide Time: 30:30)

EXAMPLE:

Consider 1<sup>st</sup> order AR model:

AR<sub>1</sub> model.

$$\hat{x}(m) = \beta x(m-1)$$

$\beta = ?$

$$\beta = \frac{\Gamma_{xx}(m)x(m-1)}{\Gamma_{xx}(m-1)x}$$

Consider 1<sup>st</sup> order AR model.

$$\hat{x}(m) = \beta x(m-1)$$

$\beta = ?$

$$\beta = \frac{\Gamma_{xx}(m)x(m-1) \cdot \Gamma_{xx}^{-1}(m-1)x(m-1)}{\Gamma_{xx}(1) \cdot \Gamma_{xx}^{-1}(0)}$$

$$\beta = \frac{\Gamma_{xx}(1)}{\Gamma_{xx}(0)}$$

Now, let us look at a simple example to understand this as usual because when we do simple examples, we tend to understand things better so, always, always support or enhance your understanding, we are trying to work out a simple example, like that always helps in significantly improving your understanding.

So, let us look at a first order AR model the simplest, consider a first order AR model although simple, this is used very frequently, this is simply termed as AR 1 that is AR subscript 1 model and of course AR model of order n you can determine denote using ARn

so, AR 1 model, which means you are trying to form the prediction  $\hat{x}_n$  of  $x_n$  equals  $\beta$  times  $x_{n-1}$ , what is  $\beta$ ?

And the answer to that is  $\beta$  equals your well,  $R_{xx}(1)$  times  $R_{xx}(0)$  inverse which is  $R_{xx}(1)$  divided by  $R_{xx}(0)$  inverse, which is nothing but,  $R_{xx}(1)$  divided by  $R_{xx}(0)$

(Refer Slide Time: 32:30)

The image shows a whiteboard with handwritten mathematical derivations. At the top,  $\gamma_{xx}(0)$  is written in green. Below it, the prediction equation is given as  $\hat{x}(n) = \frac{\gamma_{xx}(1)}{\gamma_{xx}(0)} x(n-1)$ , with an arrow pointing to the fraction and the label  $a_1 = \beta$ . A horizontal line separates this from the text "First order auto Regressor". Below this, the regression error variance is calculated:  $\sigma_e^2 = \gamma_{xx}(0) - a_1 \gamma_{xx}(1)$ , with an arrow pointing to the term  $\sigma_e^2$  and the label "Regression error". This is further simplified to  $\sigma_e^2 = \gamma_{xx}(0) - \frac{\gamma_{xx}(1)}{\gamma_{xx}(0)} \gamma_{xx}(1)$ . The final result is  $=$ .

So, therefore your optimal prediction that is  $\hat{x}_n$  this is simply  $R_{xx}(1)$  divided by  $R_{xx}(0)$  into this is essentially your first order auto-regressor, this is essentially your first order AR 1 model that is your  $\hat{x}_n$  equals  $R_{xx}(1)$  divided by  $R_{xx}(0)$  times  $x_{n-1}$ . And now, one can ask what is the modelling error or what is the regression error?

This is essentially your  $R_{xx}(0)$  minus  $a_1$  times  $R_{xx}(1)$  remember this is your  $a_1$  equals  $\beta$  so, this is going to be your  $R_{xx}(0)$  minus  $R_{xx}(1)$  divided by  $R_{xx}(0)$  times  $R_{xx}(1)$  which is essentially equal to  $R_{xx}(0)$  minus  $R_{xx}(1)$  divided by  $R_{xx}(0)$ , so this is essentially your regression error, this is essentially your regression error for this first order AR model.

So, essentially that completes our discussion of the AR modelling that is auto-regression, which is a special case of regression. Essentially, we are trying to regress using the past samples of the same process and we are using the property that these samples are wide sense stationary.

So, essentially the correlation that is what we call as the ACF function that depends only on the lag, that is the expected value of  $x_n$  minus 1  $x_n$  minus  $i$  into  $x_n$  minus  $j$  is  $R_{xx}(i - j)$ . So, that completes this discussion which I have already said is very important as many applications in forecasting, coding, compression, etc. So, please take a look at this again we will come back, we will discuss, continue our discussion of other similar concepts in the subsequent models. Thank you very much.
