Conditional Gaussian Density – Covariance

Hello, welcome to another module in this massive open online course. So, we are looking at the conditional Gaussian probability density function and let us continue our discussion.

(Refer Slide Time: 0:24)

So, one of the important concepts or principles of linear algebra is the Conditional Gaussian, the Conditional Gaussian PDF and we are specifically looking at a scenario where you have two

quantities \bar{y} , \bar{h} these are jointly Gaussian, typically you would like to consider a scenario where for instance \bar{y} is an observation. So, we have a set of observations and \bar{h} is an unknown to be estimated, an unknown quantity, this quantity is to be, this is an unknown quantity that is to be estimated.

(Refer Slide Time: 1:44)

Handwritten slide content:

$$h|\bar{y} \sim \text{GAUSSIAN.}$$

$$E\{h|\bar{y}\} = R_{hy} R_y^{-1} \bar{y}$$

↑
CONDITIONAL MEAN

Handwritten slide content:

$$E\{h|\bar{y}\} = R_{hy} R_y^{-1} \bar{y}$$

↑
CONDITIONAL MEAN

COVARIANCE MATRIX
 $\text{cov}(h|\bar{y}) = ?$

And we have seen that the conditional mean that is we have \bar{y} or we have this probability density function, conditional probability density function \bar{h} given \bar{y} this is Gaussian, in fact the conditional mean that is what we established last time, if you go back and take a look at it is that expected value of \bar{h} given \bar{y} , this is what we call as the conditional mean,

conditional mean of \bar{h} conditioned on \bar{y} . This has an interesting structure, this is R_{hy} , cross covariance of \bar{h} and \bar{y} times R_y inverse into \bar{y} this is the conditional mean.

Now, in order to determine the PDF we also have to determine the covariance of \bar{h} power given \bar{y} . So, you ask the question what is remaining is the covariance, in particular the conditional covariance, the covariance matrix, in particular the conditional covariance, so we have this denoted by this covariance of \bar{h} bar given \bar{y} bar, what is this quantity?

(Refer Slide Time: 3:20)

The image shows a whiteboard with the following handwritten text:

$$\bar{z} = \bar{h} - R_{hy} R_y^{-1} \bar{y}$$

$$E\{\bar{z} \bar{y}^T\} = 0$$

$\Rightarrow \bar{z}, \bar{y}$ UNCORRELATED
 $\Rightarrow \bar{z}, \bar{y}$ ARE INDEPENDENT SINCE GAUSSIAN.

$$\Rightarrow \text{COV}(\bar{z} | \bar{y}) = \text{COV}(\bar{z})$$

Now, to do that let us start first once again with the covariance of this quantity \bar{z} bar given \bar{y} bar, where you remember \bar{z} bar is something we had defined as \bar{h} bar minus R_{hy} into R_y inverse into \bar{y} bar. So, we had constructed this vector \bar{z} bar, remember to aid us in this derivation, so \bar{z} bar equals \bar{h} bar minus R_{hy} R_y inverse into \bar{y} bar.

Now, we ask the question what is the covariance of this, now the other thing that we had seen is that expected value of \bar{z} bar \bar{y} bar transpose this equal to 0, which implies these are uncorrelated, implies \bar{z} bar comma \bar{y} bar these are uncorrelated and this also implies \bar{z} bar comma \bar{y} bar are independent, these are independent, \bar{z} bar \bar{y} bar are independent you can also say these are independent since they are Gaussian.

And therefore, now what does that mean and therefore, now this now since \bar{z} bar and \bar{y} bar these are independent, this essentially implies covariance of \bar{z} bar given \bar{y} bar this is simply equal to the covariance of \bar{z} bar, because \bar{z} bar and \bar{y} bar are independent. So, probability density function

of \bar{z} given \bar{y} is simply the probability density function of \bar{z} . Therefore, the covariance of \bar{z} given \bar{y} is simply the covariance of \bar{z} , because \bar{z} and \bar{y} are essentially independent.

(Refer Slide Time: 5:36)

$\Rightarrow \bar{z}, \bar{y}$
 ARE INDEPENDENT
 SINCE GAUSSIAN.

$$\Rightarrow \text{Cov}(\bar{z} | \bar{y}) = \text{Cov}(\bar{z})$$

$$E\left\{ \bar{z} \bar{z}^T \right\} = E\left\{ (\bar{h} - R_{hy} R_y^{-1} \bar{y}) (\bar{h} - R_{hy} R_y^{-1} \bar{y})^T \right\}$$

$$E\left\{ \bar{z} \bar{z}^T \right\} = E\left\{ (\bar{h} - R_{hy} R_y^{-1} \bar{y}) (\bar{h} - R_{hy} R_y^{-1} \bar{y})^T \right\}$$

$$= E\left\{ (\bar{h} - R_{hy} R_y^{-1} \bar{y}) (\bar{h}^T - \bar{y}^T R_y^{-1} R_{yh}) \right\}$$

$R_{hy}^T = R_{yh}$

Now, we simplify this covariance of \bar{z} , this you can derive as covariance, remember \bar{z} is a 0 mean random variable. So, covariance of \bar{z} is expected value of $\bar{z} \bar{z}^T$ which if you simplify it use the expression for \bar{z} this expected value of, you have your \bar{h} minus R_{hy} , \bar{h} minus $R_{hy} R_y^{-1} \bar{y}$ into \bar{h} minus $R_{hy} R_y^{-1} \bar{y}$ transpose which is

equal to expected value of, let me simplify this, $\bar{h} - R_{hy} R_y^{-1} \bar{y}$ into $\bar{h} \bar{h}^T - R_{hy} R_y^{-1} \bar{y} \bar{h}^T - \bar{h} \bar{y}^T R_y^{-1} R_{yh} + R_{hy} R_y^{-1} \bar{y} \bar{y}^T R_y^{-1} R_{yh}$ or taking the transpose of this quantity.

This becomes $\bar{y}^T R_y^{-1} R_{yh}$ because R_y is a symmetric matrix and $R_{hy}^T = R_{yh}$. So, we use the property here that $R_{hy}^T = R_{yh}$, this is something that we had established before, this is easy to see because R_{hy} is nothing but expected of $\bar{h} \bar{y}^T$ and R_{yh} is expected of $\bar{y} \bar{h}^T$ and these are transpose of each other.

(Refer Slide Time: 7:28)

$$\begin{aligned}
 &= E \left\{ \bar{h} \bar{h}^T - R_{hy} R_y^{-1} \bar{y} \bar{h}^T - \bar{h} \bar{y}^T R_y^{-1} R_{yh} + R_{hy} R_y^{-1} \bar{y} \bar{y}^T R_y^{-1} R_{yh} \right\} \\
 &= R_h - R_{hy} R_y^{-1} R_{yh} + R_{hy} R_y^{-1} R_{yh}
 \end{aligned}$$

$R_{hy}^T = R_{yh}$

Therefore, now if we simplify this quantity you will have, this is the expected value of, well writing a term by term $\bar{h} \bar{h}^T - R_{hy} R_y^{-1} \bar{y} \bar{h}^T - \bar{h} \bar{y}^T R_y^{-1} R_{yh} + R_{hy} R_y^{-1} \bar{y} \bar{y}^T R_y^{-1} R_{yh}$ and this is equal to, take the expected value of $\bar{h} \bar{h}^T$ this is R_h minus $R_{hy} R_y^{-1} R_{yh}$ plus $R_{hy} R_y^{-1} R_{yh}$ and this is equal to, take the expected value of $\bar{y} \bar{y}^T$ this is R_y into R_y^{-1} into R_{yh} and needless to say this $R_y^{-1} R_y$ this is identity, so this becomes your, these things cancel so this becomes identity.

This is R_{yh} minus expected of $\bar{h} \bar{y}^T R_y^{-1} R_{yh}$, this is R_{yh} into R_y^{-1} , I am sorry, this has to be R_{yh} subscript h , R_{yh} plus you have $R_{hy} R_y^{-1} R_{yh}$ expected value of $\bar{y} \bar{y}^T$ this is R_y into R_y^{-1} into R_{yh} and needless to say this $R_y^{-1} R_y$ this is identity, so this becomes your, these things cancel so this becomes identity.

(Refer Slide Time: 9:29)

$$= R_h - R_{hy} R_y^{-1} R_{yh} - K_{hy} R_y^{-1} R_{yh} + R_{hy} R_y^{-1} R_y R_y^{-1} R_{yh}$$

$$\text{cov}(\bar{z}|\bar{y}) = \text{cov}(\bar{z}) = E\{\bar{z}\bar{z}^T\}$$

$$= R_h - 2R_{hy} R_y^{-1} R_{yh} + R_{hy} R_y^{-1} R_{yh}$$

And therefore, you are left with the result that the covariance matrix of \bar{z} given \bar{y} equals the covariance of \bar{z} which is essentially since this \bar{z} is 0 mean, this is $\bar{z} \bar{z}^T$, this is R_h minus, you can see R_y inverse R_{yh} minus twice this plus again the same quantity $R_{hy} R_y$ inverse R_{yh} .

(Refer Slide Time: 10:14)

$$+ K_{hy} R_y^{-1} R_{yh}$$

$$\text{cov}(\bar{z}|\bar{y}) = R_h - R_{hy} R_y^{-1} R_{yh} = \text{cov}(\bar{z})$$

$$\text{cov}(\bar{h}|\bar{y}) = ? \quad \text{CONSTANT GIVEN } \bar{y}$$

$$= \text{cov}(\bar{h} - R_{hy} R_y^{-1} \bar{y} | \bar{y})$$

And now if you simplify this you get this is essentially R_h minus $R_{hy} R_y$ inverse R_{yh} , so this is the covariance of \bar{z} given \bar{y} , which is very interesting or which is essentially also the covariance of \bar{z} . Now, remember ultimately we want to ask the question what is the

covariance of \bar{h} given \bar{y} , this is the thing that we set out to derive and if you look at this we substitute \bar{z} , we substitute for the vector \bar{z} here which is \bar{z} equals.

Remember, \bar{h} minus R_{hy} into R_y inverse into \bar{y} so this is equal to the covariance of \bar{h} bar minus $R_{hy} R_y$ inverse \bar{y} given \bar{y} bar, but now look at this, the covariance of now this quantity given \bar{y} bar, this quantity is a constant, this quantity is a constant given \bar{y} bar.

(Refer Slide Time: 11:44)

SUBTRACTING CONSTANT
DOES NOT AFFECT COV

GIVEN \bar{y} , $R_{hy} R_y^{-1} \bar{y}$
BECOMES CONSTANT!

$$\text{cov}(\bar{z} | \bar{y}) = \text{cov}(\bar{h} | \bar{y})$$

$$= R_h - R_{hy} R_y^{-1} R_{yh}$$

So, given \bar{y} bar, given \bar{y} bar you have $R_{hy} R_y$ inverse \bar{y} bar this quantity becomes constant and therefore, this is equal to simply now you are subtracting a constant from \bar{h} bar. Now, subtracting a constant does not affect the covariance or variance therefore, this is also equal to the covariance of \bar{h} bar given \bar{y} bar.

So, therefore, since subtracting a constant does not affect the covariance, so subtracting constant does not affect constant, so this is equal to the covariance of \bar{h} bar given \bar{y} bar. So, what we are saying is the covariance of \bar{z} bar given \bar{y} bar equals covariance of \bar{h} bar given \bar{y} bar which now you can write as R_h minus R_{hy} into R_y inverse R_{yh} this is essential.

(Refer Slide Time: 13:25)

$$\text{cov}(h|y) = \text{cov}(h) - R_{hy} R_y^{-1} R_yh$$

$$= R_h - R_{hy} R_y^{-1} R_yh$$

$$h|y \sim \mathcal{N}(R_{hy} R_y^{-1} \bar{y}, R_h - R_{hy} R_y^{-1} R_yh)$$

Gaussian
 CONDITIONAL MEAN
 CONDITIONAL COV.
 CONDITIONAL Gaussian PDF of $h|y$

And therefore, now you can write \bar{h} given \bar{y} this is Gaussian, remember this shows that the PDF is Gaussian or multivariate Gaussian, the mean is $R_{hy} R_y^{-1} \bar{y}$, this is the conditional mean and the conditional covariance is $R_h - R_{hy} R_y^{-1} R_yh$. This is the conditional Gaussian PDF, so this is the conditional Gaussian PDF of \bar{h} given \bar{y} , this is the conditional Gaussian PDF of \bar{h} given \bar{y} , this is the conditional mean, this is the conditional covariance, this is the conditional mean, this is a conditional covariance.

Now, if you look at it, now if you go if you think about it there is something that is very interesting, there is something that we have already seen, my claim is there is something that we already seen, if you go all the way back and take a look at what is known as this principle of this LMMSE estimation, the Linear Minimum Mean Square Error Estimate, if you go all the way back.

(Refer Slide Time: 15:16)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it says $\Rightarrow C = R_{xy} R_{yy}^{-1}$. Below that, it says $\Rightarrow \hat{x} = C \bar{y}$ with a pink arrow pointing to the text "LMMSE Estimate". Below that, it says $\Rightarrow \hat{x} = R_{xy} R_{yy}^{-1} \bar{y}$, which is circled in purple. A bracket below this equation points to the text "LMMSE Linear Minimum Mean Square Error Estimate of \bar{x} ". At the bottom of the whiteboard, it says "Minimum MSE".

Let me just refresh your memory a little bit, you go all the way back and you look at this quantity, if you look at this quantity this is something that you should have already seen which is essentially that ah this thing that is if you look at the LMMSE estimate, this is of \bar{x} given \bar{y} , that is essentially same thing we have replaced x by \hat{x} , this essentially is your LMMSE estimate.

And now if you look at this you will exactly get the same kind of expression what you are observing here, is that if you denote this by what is known as the MMSE, this quantity is what is known as the MMSE estimate, that is the Minimum Mean Square Error estimate.

(Refer Slide Time: 16:12)

ESTIMATE.

$$\hat{h} = E\{h | \bar{y}\} \quad \text{LMMSE Estimate}$$
$$\hat{h} = R_{hy} R_y^{-1} \bar{y}$$

h, \bar{y} are jointly Gaussian
This is the Minimum mean Square Error Estimate.

MMSE
 $\min E\{\|\hat{h} - h\|^2\}$

$$\hat{h} = R_{hy} R_y^{-1} \bar{y}$$

h, \bar{y} are jointly Gaussian
This is the Minimum mean Square Error Estimate.

MMSE
 $\min E\{\|\hat{h} - h\|^2\}$

For h, \bar{y} GAUSSIAN
BEST LINEAR MMSE ESTIMATE
= BEST MMSE ESTIMATE.

That is it can be shown that if you set the estimate, remember \hat{h} is unknown, if you set the estimate of \hat{h} , remember \bar{h} is an unknown quantity, we are trying to estimate \bar{h} after observing \bar{y} and therefore, one way to derive this estimate of \bar{h} is to set it as the conditional mean of \bar{h} given \bar{y} , that is set it as expected value of \bar{h} given \bar{y} which essentially is the $R_{hy} R_y^{-1} \bar{y}$ which is R_{hy} into R_y^{-1} into \bar{y} and which is exactly as the LMMSE estimate.

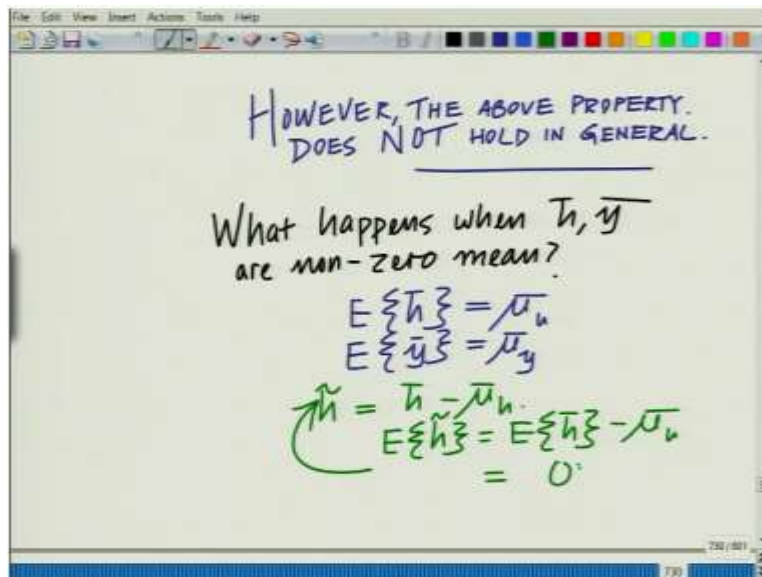

So, which is exactly as the LMMSE estimate and this quantity here when \bar{h} and \bar{y} are jointly Gaussian this becomes the LMMSE estimate, so when \bar{h} , this is the MMSE estimate, that is

the minimum mean, MMSE by MMSE mean this is the minimum mean squared error estimate. So, this becomes the MMSE estimate, that is it minimizes, that is if you ask the quantity what is the estimate \hat{h} such that $\hat{h} - \bar{x}$ norm square, the mean of that, the mean square error is minimum that is this MMSE estimate.

So, what you see is that the MMSE estimate is equal to the LMMSE estimate when the \bar{h} and \bar{y} are jointly Gaussian, which is what we already seen, which the LMMSE estimate is something that we already seen, what we are seeing now is something new that is the MMSE estimate and much harder to derive, but for the Gaussian the MMSE estimate is equal to the LMMSE estimate, that is the best linear estimate, that is the best linear estimate itself is the best estimate however, this does not hold for other PDF.

So, something important to note here is for Gaussian, that is for Gaussian for \bar{h} \bar{y} Gaussian the best that is LMMSE, that is the best linear estimate, best linear MMSE estimate equals the best MMSE estimate. However, this is an important property of the Gaussians, this is a very important property for Gaussian random vectors however, this does not hold for others.

(Refer Slide Time: 20:01)

In general however, this is a very interesting property however, the above property does not hold in general, this something where is very important, that is the best LMMSE estimate need not be the best MMSE estimate, this only holds when it is a Gaussian.

Now, let us consider what happens when you have 0 mean, I think we have already seen this but we can also consider this once more, what happens when \bar{h} comma \bar{y} are non 0 mean? Well, very simple, if they are non 0 mean we define these new quantities, let us say expected value of \bar{h} equal to $\mu_{\bar{h}}$ and expected value of \bar{y} equal to $\mu_{\bar{y}}$ then we define these new quantities, we define \tilde{h} equals \bar{h} minus $\mu_{\bar{h}}$ and now observe that expected value of \tilde{h} , this tilde quantity equals expected value of \bar{h} minus $\mu_{\bar{h}}$ which is equal to 0.

(Refer Slide Time: 22:03)

Handwritten mathematical derivation on a whiteboard:

$$\tilde{y} = \bar{y} - \mu_{\bar{y}} \quad \text{Zero mean Qty}$$

$$E\{\tilde{h}\tilde{h}^T\} = R_h = E\{(\bar{h} - \mu_{\bar{h}})(\bar{h} - \mu_{\bar{h}})^T\}$$

$$E\{\tilde{y}\tilde{y}^T\} = R_y = E\{(\bar{y} - \mu_{\bar{y}})(\bar{y} - \mu_{\bar{y}})^T\}$$

Handwritten mathematical derivation on a whiteboard:

$$E\{\tilde{h}\tilde{h}^T\} = R_h = E\{(\bar{h} - \mu_{\bar{h}})(\bar{h} - \mu_{\bar{h}})^T\}$$

$$E\{\tilde{y}\tilde{y}^T\} = R_y = E\{(\bar{y} - \mu_{\bar{y}})(\bar{y} - \mu_{\bar{y}})^T\}$$

$$E\{\tilde{h}\tilde{y}^T\} = E\{(\bar{h} - \mu_{\bar{h}})(\bar{y} - \mu_{\bar{y}})^T\} = R_{hy}$$

Similarly, we define these tilde quantity \tilde{y} equals \bar{y} minus the expected value of \bar{y} that is μ_y and this is also another zero mean quantity. Now, we can estimate in terms of this tilde quantities now we say expected value of \tilde{h} \tilde{h}^T let us say this is equal to its still denoted by R_h , which is R_h which is nothing but expected value of because this is nothing but expected value of R_h is now nothing but expected value of $\bar{h} \bar{h}^T - \mu_h \mu_h^T$, because the shifting by the mean that does not affect the covariance. So, covariance of \bar{h} and \tilde{h} will still be the same.

Similarly, the covariance of \bar{y} and \tilde{y} that is expected value of, $\tilde{y} \tilde{y}^T$ equals R_y equals expected value of $\bar{y} \bar{y}^T - \mu_y \mu_y^T$, I am sorry, $\bar{y} \bar{y}^T - \mu_y \mu_y^T$ into $\bar{y} \bar{y}^T - \mu_y \mu_y^T$. And similarly, you have your R_{hy} that will become expected value of $\tilde{h} \tilde{y}^T$ equals $\bar{h} \bar{y}^T - \mu_h \mu_y^T$ into $\bar{h} \bar{y}^T - \mu_h \mu_y^T$ this is equal to your R_{hy} .

(Refer Slide Time: 24:00)

The image shows a whiteboard with handwritten mathematical equations. The top equation is $\tilde{h} | \tilde{y} = \mathcal{N}(R_{h\tilde{y}} R_{\tilde{y}}^{-1} \tilde{y}, R_{\tilde{h}} - R_{h\tilde{y}} R_{\tilde{y}}^{-1} R_{\tilde{y}} \tilde{h})$. Below it, the same expression is written as $\mathcal{N}(R_{h\tilde{y}} R_{\tilde{y}}^{-1} (\tilde{y} - \mu_{\tilde{y}}), R_{\tilde{h}} - R_{h\tilde{y}} R_{\tilde{y}}^{-1} R_{\tilde{y}} \tilde{h})$. A curved arrow points from the first equation to the second. Below the second equation, the expression $\tilde{h} - \mu_{\tilde{h}} | \tilde{y} - \mu_{\tilde{y}}$ is written, with an arrow pointing from the mean term in the second equation to this expression.

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is an equation:
$$= \mathcal{N}(R_{hy} R_y^{-1} (\bar{y} - \bar{\mu}_y), R_h - R_{hy} R_y^{-1} R_{yh})$$
 A blue arrow points from this equation down to the next one. Below it, the expression $\bar{h} - \bar{\mu}_h | (\bar{y} - \bar{\mu}_y)$ is written, with a red circle around $(\bar{y} - \bar{\mu}_y)$ and a red arrow pointing to the text "CONDITIONAL GAUSSIAN PDF" written in red. Below this, the final expression is written:
$$\bar{h} | \bar{y} \sim \mathcal{N}(R_{hy} R_y^{-1} (\bar{y} - \bar{\mu}_y) + \bar{\mu}_h, R_h - R_{hy} R_y^{-1} R_{yh})$$

And now you put these things together now you will have the conditional PDF of \tilde{h} given \tilde{y} this is basically a Gaussian with mean you will have $R_{\tilde{h}|\tilde{y}}$ into $R_{\tilde{y}}$ inverse into \tilde{y} into the conditional covariance that is $R_{\tilde{h}} - R_{\tilde{h}\tilde{y}} R_{\tilde{y}}^{-1} R_{\tilde{y}\tilde{h}}$, which again if you replace these quantities by their logical equivalents it is not very difficult to see that this is kind Gaussian.

Because $R_{\tilde{h}\tilde{y}}$ is R_{hy} this is R_y inverse and this one becomes $\bar{y} - \bar{\mu}_y$ and this quantity the other quantity that is the covariance becomes $R_h - R_{hy} R_y^{-1} R_{yh}$ and this is \tilde{h} given \tilde{y} but \tilde{h} , remember what is \tilde{h} ? \tilde{h} is simply your $\bar{h} - \bar{\mu}_h$ conditioned on $\bar{y} - \bar{\mu}_y$ this has this PDF.

So, you are simply subtracting which means \bar{h} , to get the PDF of \bar{h} all you have to do or \bar{h} given $\bar{y} - \bar{\mu}_y$ that is $\bar{y} - \bar{\mu}_y$ or \bar{h} given simply \bar{y} , because \bar{y} and $\bar{y} - \bar{\mu}_y$ that is PDF of \bar{h} given \bar{y} is the same as the PDF of \bar{h} given $\bar{y} - \bar{\mu}_y$ because these are \bar{y} and $\bar{y} - \bar{\mu}_y$ simply differ by the shift.

So, this becomes now all you have to do is you have to add the mean to this. So, $\bar{h} - \bar{\mu}_h$ as this mean, so \bar{h} will have the mean $R_y^{-1} (\bar{y} - \bar{\mu}_y) + \bar{\mu}_h$ and the covariance will not, the covariance does not remain unchanged, does not change because remember, simply shifting by the mean or shifting by a mean does not affect and this is the final expression for the conditional Gaussian PDF and which is very useful.

And as I said arises, this is the expression for the conditional Gaussian PDF which is very useful and arises very frequently for instance arises in machine learning, data analytics, signal processing, communication is there everywhere in the principle and this remember I already told you relates to the principle of MMSE estimation, the minimum mean squared error estimation. So, this has a lot of use in that sense.

So, that is wonderful, so I think we have covered this, we have, I hope all of you have been able to appreciate and completely understand this concept of the conditional probability, Gaussian probability density function that is when \bar{h} and \bar{y} are jointly Gaussian random vectors given \bar{y} what is the conditional PDF of \bar{h} and that then determines what is the estimate MMSE estimate of \bar{h} given \bar{y} which is nothing but the conditional expectation of \bar{h} given \bar{y} . So, let us stop here and we will continue with equivalent modules, thank you very much.
