Lecture - 19
IIR Filters (Contd.)

(Refer Slide Time: 00:36)

Good morning friends, we shall continue our discussions on IIR filter.

(Refer Slide Time: 00:49)

LECTURE # 19.

$$|H_n(j\omega)|^2 = \frac{1}{1 + \epsilon^2 C_n^2\left(\frac{\omega_s}{\omega_p}\right)}$$

$$= \frac{1}{1 + \epsilon^2 \left\{ \cosh N \cosh^{-1}\left(\frac{\omega_s}{\omega_p}\right) \right\}^2}$$

$\cosh^{-1}(N \cosh^{-1} \omega) \Rightarrow |\omega| \leq 1$
 $\cosh(N \cosh^{-1} \omega) \Rightarrow |\omega| > 1$

$$= \frac{1}{A^2}$$

$$\sqrt{\frac{A^2 - 1}{\epsilon^2}} = \cosh N \cosh^{-1}\left(\frac{\omega_s}{\omega_p}\right)$$

$$N = \frac{\cosh^{-1}\left(\sqrt{\frac{A^2 - 1}{\epsilon^2}}\right)}{\cosh^{-1}\left(\omega_s/\omega_p\right)}$$

If you remember, yesterday we are discussing about chebyshev filter. Now, we can write the chebyshev function in the analog domain as; $1 + \epsilon^2 C_n^2(\omega_s/\omega_p)$ is a function of ω_s/ω_p . This is in terms of stop band and pass band ratio. So, this can be written as $1 + \epsilon^2 \left\{ \cosh N \cosh^{-1}\left(\frac{\omega_s}{\omega_p}\right) \right\}^2$ as I had mentioned yesterday; $\cosh N$, $\cosh^{-1} \omega$ for $\omega < 1$ and it is $\cosh N$, $\cosh^{-1} \omega$ for $\omega > 1$ and both of them generate the same polynomial functions.

So, $\cosh N \cosh^{-1}(\omega_s/\omega_p)$ squared, C_n^2 mean, this is C_n^2 and that is equal to $1/A^2$ where if you remember; we had mentioned in our earlier characteristics, the quantities A and ϵ , I will just refer back to the earlier notes. So, this was given as $1/A^2$ and this was the tolerance in the pass band, okay. So, will refer to the same quantity A and that will be equal to $1/A^2$ when it is in the stop band, okay.

So, $A^2 - 1/\epsilon^2$ is equal to $\cosh N \cosh^{-1}(\omega_s/\omega_p)$, which gives me $N = \frac{\cosh^{-1}\left(\sqrt{\frac{A^2 - 1}{\epsilon^2}}\right)}{\cosh^{-1}\left(\omega_s/\omega_p\right)}$, okay. So, this is how you determine the value of N which is equal to $\cosh^{-1} 1/k$.

(Refer Slide Time: 03:57)

$$= \frac{\cosh^{-1}(1/\kappa)}{\cosh^{-1}(1/\kappa)}$$

$$\gamma = \left[\frac{\sqrt{1+\epsilon^2} + 1}{\epsilon} \right]^{1/N}$$

$$\zeta_1 = \frac{\gamma^2 + 1}{\gamma} \quad \zeta_2 = \frac{\gamma^2 - 1}{\gamma}$$

$$\text{Roots} = p_k = \sigma_k + j\omega_k$$

$$\sigma_k = -\rho \cdot \zeta_1 \cdot \sin\left[\frac{(2k-1)\pi}{2N}\right]$$

$$\omega_k = \rho \cdot \zeta_2 \cdot \cos\left[\frac{(2k-1)\pi}{2N}\right]$$

You defined the two quantities, $k-1$ and it comes like this. So, the polynomials can be framed, you have to get the roots. So, say γ equal to; basically the chebyshev roots will be lying on an ellipse okay, so if you are given ϵ , if you are given ϵ then you can write this $1 + \epsilon^2$ plus 1 divided by ϵ to the power $1/N$, ζ equal to $\gamma^2 + 1$ by γ .

And they are two different entities; it becomes little difficult, I will call it 1 and 2 to distinguish because our hand writings are not matching with the prints. Our roots will be p_k equal to $\sigma_k + j\omega_k$; these are the roots k th root, so σ_k is given by $-\rho \zeta_1 \sin\left[\frac{(2k-1)\pi}{2N}\right]$, okay. And ω_k is equal to $\rho \zeta_2 \cos\left[\frac{(2k-1)\pi}{2N}\right]$, okay. Basically, they represent major axis and minor axis of the ellipse ρ times this.

There are other ways of looking at this chebyshev polynomials. There are many books where they refer to the direct design tables and we will discuss that at a later stage. Let us come back to what we are discussing yesterday. I had given you a small problem to try at home, did you try that?

(Refer Slide Time: 06:51)

Handwritten derivation on a grid background:

$$f(t) \rightarrow f_s(t)$$

$$f_s(t) = f(t) \sum_{k=0}^{\infty} \delta(t - kT)$$

$$= \sum f(kT) \cdot \delta(t - kT)$$

$$\int \sum \delta(t - kT) = \sum e^{-skT}$$

$$F_s(s) \Rightarrow \sum_{k=0}^{\infty} f(kT) \cdot e^{-skT} = F(z) \Big|_{z = e^{sT}}$$

$$F_s(s) = \frac{1}{T} \sum F(s + jn\omega_s)$$

A small sketch to the right shows a continuous function being sampled at regular intervals T, with vertical lines representing the sampling points.

You can see, $f(t)$ we are considering in the discretized form as $f_s(t)$, okay. I can write, say sample values of a continuous function as $f(t)$ multiplied by a series of delta functions at regular intervals of capital T , T is the sampling time, okay; k varying from 0 to infinity. So, if this is your $f(t)$, we are multiplying by delta functions.

So, these are the sample values. So, delta functions of unit magnitude at regular intervals that will give me; $f(kT)$ as the weightage of that delta function, I can write like this. Now Laplace transform of delta t minus kT is e to the power minus $s k T$ okay summation, is it not? These are shifted function, shifted impulse and series of shifted impulse; so it will be giving me a summation over k , this functions okay.

So, if I call the Laplace transform as F subscript s ; this will be Laplace transform of this okay which will be $f(kT) e$ to the power minus $s k T$, do you all agree? So, this is nothing but z transform, evaluated at z is equal to e to the power $s T$ basically, is it not? This is by definition, z transform; if I substitute for e to the power $s T$ z then this becomes z transform. So, $F_s(s)$ will be $1/T$ summation, this is a proof that I asked you to try out okay. Let me write $n s \omega_s T$; instead of that I will write capital ω_s , this is sampling frequency in the analog domain.

(Refer Slide Time: 10:04)

$$\mathcal{L}\{\sum \delta(t-kT)\} = \sum e^{-skT}$$

$$F_s(s) \Rightarrow \sum_{k=0}^{\infty} f(kT) \cdot e^{-skT} = F(z)$$

$$F_s(s) = \frac{1}{T} \sum_{n=-\infty}^{\infty} F(s + jn\omega_s) \quad z = e^{sT}$$

Will do that, that means whatever value of S you are having; you replace s by s plus $j n \omega_s$ and n varying from minus infinity to plus is infinity, okay. This is what we have got, basically this is the the situation from where we are getting aliasing.

(Refer Slide Time: 10:32)

$$F_a(s) = \frac{A_1}{s+s_1} + \frac{A_2}{s+s_2} + \dots$$

$$F_s(s) = ?$$

$$\frac{A_1}{s+s_1} \Rightarrow f_1(t) = A_1 \cdot e^{-s_1 t}$$

$$F_{s_1}(s) = A_1 \cdot \sum e^{-s_1 kT} \cdot e^{-skT}$$

$$= \frac{A_1}{1 - e^{-(s+s_1)T}}$$

$$e^{-(s+s_1)T} = 1 = e^{j2\pi n}$$

See let $F(s)$, $F(s)$ be $A_1/s + s^{-1} + A_2/s + s^{-2}$ and so on. Let us consider only one of them. We are trying to find out, what would be $F(s)$ by $F(s)$. We have seen, $F(s)$ will be, F original $F(s)$ replaced by s plus this with a with an average. So, you want to derive this relation. So, let us consider only the first term, okay.

So, $A_1/s + s^{-1}$, what is its corresponding time domain response? If I call it $f_1(t)$, that is equal to $A_1 \int_0^t e^{-s t} dt$, agreed? So, $F(s) = 1/s$ that means corresponding to this, what will be $F(s)$? It will be A times A_1 times discretized version of this. If I take $e^{-s k T}$ to the power minus $s^{-1} k T$, do you agree? Is that all right because, this is $e^{-s k T}$ to the power minus $s^{-1} t$; we are taking Laplace transform of the discrete version of this, mind you $s^{-1} k T$.

I have just put t equal to $k T$, so these are the magnitudes and this is the; just in the previous step we have done, $f(k T)$ into $e^{-s k T}$. So, what is $f(k T)$? The magnitude of the function that is $e^{-s k T}$, is it not? Because the response due to this is $e^{-s k T}$ to the power minus $s^{-1} t$ that we have seen; so if I discretized it $k T$, this is the specific value at that point. So, this summation will give me $A_1 \sum_{k=0}^{\infty} e^{-s k T}$, is that all right?

So, a term like $A/s + s^{-1}$ will give me, correspondingly here $A \sum_{k=0}^{\infty} e^{-s k T}$, for the sample function. So, what are the roots of this? What are the poles of this? That means corresponding to a pole at s equal to $-s^{-1}$; the set of poles that will be generated here will be the poles for the discretized function. So, we are trying to find out the poles of this. So that means, equate this to 0 so $e^{-s k T}$ to the power minus $s^{-1} k T$ is equal to 1, all right is equal to $e^{-s k T}$ to the power $j 2 \pi n$ okay.

(Refer Slide Time: 14:23)

$$A_1 \Rightarrow f_1(t) = A_1 e^{-s_1 t}$$

$$s_1(s) = A_1 \sum_{k=0}^{\infty} e^{-s_1 k T} \cdot e^{-s k T}$$

$$= \frac{A_1}{1 - e^{-(s_1 + s)T}}$$

$$e^{-(s_1 + s)T} = 1 = e^{j 2\pi n}$$

$$s_1 + s = -\frac{j 2\pi n}{T} \quad \therefore s = (-s_1 - j \frac{2\pi n}{T})$$

So, equate this two. So, s plus s_1 is basically $j 2\pi n$; actually plus or minus is immaterial, because I can always take negative integers also, $2\pi n$ by T okay and okay. Let me put it minus then s is equal to minus s_1 , minus can be plus or minus $j 2\pi n$ by T is ω_s sample ω_s , all right. So, s is equal to minus s_1 , the root at minus s_1 will generate minus s_1 minus or plus n times $j \omega_s$, what does it mean?

(Refer Slide Time: 15:18)

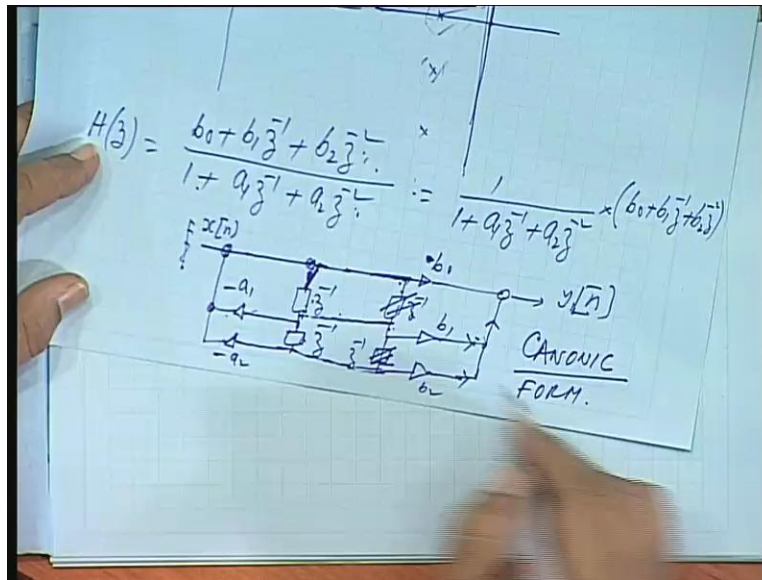

That means in the original time domain; if there is a pole here then for the discretized version this is for the continuous function, then for the discretized version in the s domain, we will have poles and infinite number of such poles at regular intervals of ω_s , okay. Now, the effect of when I am travelling along this, you traverse the entire ω_s of the imaginary axis. So, if I go along this at any point, what is the amplitude? I compute the amplitude by taking the zeros distances of zeros and poles.

Suppose there are zeros also, so there will be zeros correspondingly multiplied here; we are concentrating on one single pole, there can be a large number of poles in the family, large number of poles and zeros for the original one, so the entire set will be repeated. Now, at any point if I want to find out the magnitude in the discrete domain; if I want to find out the magnitude of the function then all such distances of poles and zeros will have to be taken out, then these distances will also influence, these distances will also influence, all right.

So, at any frequency if you consider the distances of poles and zeros and take that ratio of the products, that will decide the magnitude and if you do not eliminate the influence of these; that means they have to be widely separated okay, they are to be widely separated that means this ω_s should be very very large, that means sampling frequency should be large, otherwise there will be aliasing. So, this is the logic for having ω_s very large.

Now we will take up some examples, before we go there; there was one question raised after the class that is, can we avoid we are giving examples of impulse invariance and step invariance, for step invariance we found there are two delay elements all right, is it necessary to have two delay elements? So, it is not. So, suppose you have a function say $H(z)$, I will take a simple biquad; 0 plus $b_1 z^{-1}$ inverse plus $b_2 z^{-2}$ to the power minus 2, sorry okay. What would be the structure for this kind of function?

(Refer Slide Time: 18:14)

Now, I can segregate this into 1 plus a 1 z inverse plus a 2 z to the power minus 2 into another part b 0 plus b 1 z inverse plus b 2 z to the power minus 2 okay; if I consider this as part one okay, then I will have suppose x n is the input z inverse then I can have minus a 1, similarly minus a 2 another delay block z inverse and they are summated, then again they are summated here, okay.

Now, summation we normally note by a small circle and even the gain, we show by an arrow okay. Then on this side, you have b 0 z inverse b 1 then again z inverse b 2; added together that will give me y n okay, is the directional flow of information, sorry it not, minus. Now, since these two elements are appearing from the same signal, I might as well club them together. This is delay of this output, basically it is here; this is the delay of this output. This is also delay of the same signal.

So, this can be breached and I need not have these two delay elements separately. So, for a **bi-quad** I need two delay elements, all right. So, the number of delay elements in this arrangement will be depending on the highest order of the polynomials, either in the denominator or in the numerator, okay. So, this is known as the CANONIC form means; requiring minimum number

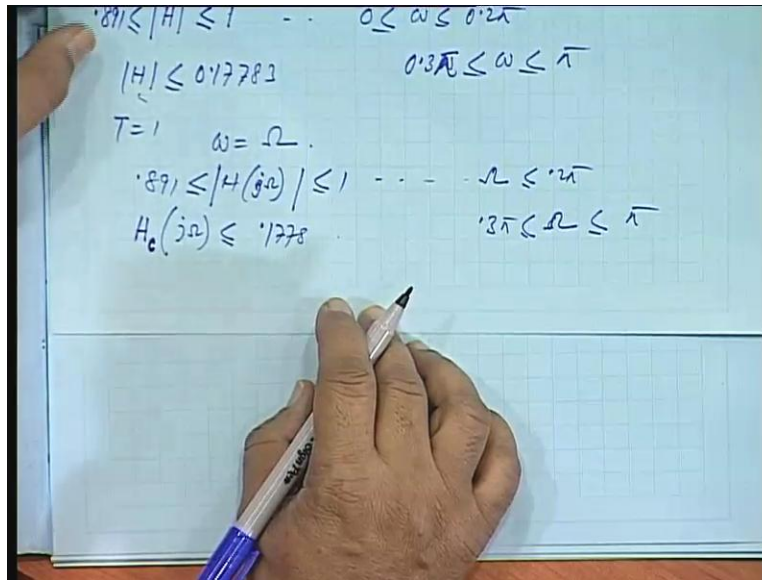

of delay elements. So with this canonic structure; in the earlier case that is for step invariance will require only a one element. Let us take some examples for filter.

(Refer Slide Time: 21:30)

Let us have a filter with these specifications; a Butterworth filter, first is to be designed to the specification that magnitude of H is less than equal to 1, on the other side it is 0.891 that means between 1 and 0.891, okay. And this is for $0 \leq \omega \leq 0.2\pi$. And H magnitude is less than equal to 0.17783 for ω between sorry, 0.3π to π , okay. That means from say 0.3π ; suppose this is 0.3π up to π , it should be within this value less than 0.177.

(Refer Slide Time: 22:56)

The specifications can be given in terms {abs} (00:22:58) absolute magnitude of the gain; some times in the logarithmic gain okay, so by impulse in variance method we are going to design this filter first. We can see in the impulse in variance, there is T coming there; so T will get cancel when we convert it, all right. So, we can take T equal to 1. So, we will put omega is equal to capital omega. So, these specifications we can write in terms of capital omega.

So, 0.891 is $H(j\omega)$, all right and $H(j\omega)$ is less than equal to 0.1778 this is in the pass band okay; that is ω less than 0.2π and here $0.3\pi \leq \omega \leq \pi$. So, H this is in the continuous domain. So, I will write H_c okay, what is given was in the discrete domain; in the continuous domain by putting ω equal to small ω equal to capital ω , we are going into the continuous domain.

(Refer Slide Time: 24:54)

Handwritten equations on a blue grid paper:

$$|H_c(j\omega)|^2 = \frac{1}{1 + \left(\frac{\omega}{\omega_c}\right)^{2N}}$$
$$(0.891)^2 = \frac{1}{1 + \left(\frac{\omega}{\omega_c}\right)^{2N}} = \frac{1}{1 + \left(\frac{2.12\pi}{0.2\pi\omega_c}\right)^{2N}}$$
$$(0.1778)^2 = \frac{1}{1 + \left(\frac{0.3\pi}{\omega_c}\right)^{2N}}$$

(Refer Slide Time: 26:36)

Handwritten equations on a blue grid paper:

$$(0.891)^2 = \frac{1}{1 + \left(\frac{\omega}{\omega_c}\right)^{2N}} = \frac{1}{1 + \left(\frac{2.12\pi}{0.2\pi\omega_c}\right)^{2N}}$$
$$(0.1778)^2 = \frac{1}{1 + \left(\frac{0.3\pi}{\omega_c}\right)^{2N}}$$

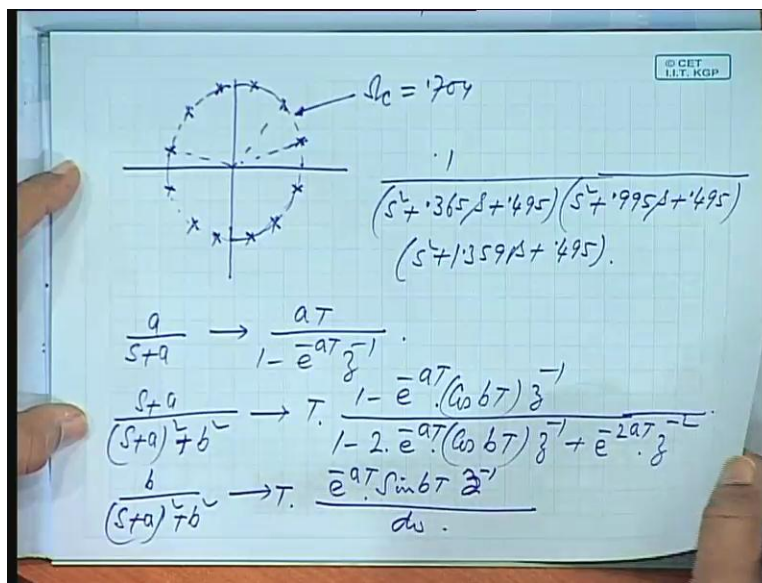

$N = 5.88$, $\omega_c = 0.704$
 $N = 6$

So, H continuous domain; the function is $1 + \omega$ by ω c to the power $2N$, this is the Butterworth filter of n th order. Now, we have to compute the two unknowns are ω c and N . So, you have compute these two quantities with these specifications. There are two inequality constants. So if you equate these, that is we are trying the border values; if you equate these two then 0.891 square, this is 0.89 square is equal to 1 by $1 + \omega$ by ω c to the power $2N$

where ω_c is corresponded point 2π , okay, the other way round, sorry 0.2π by ω_c , is it not? ω_c is unknown.

In the other case it is 0.1778 square equal to $1 + 1 + 0.3\pi$ by ω_c to the power $2N$. If you solve these two; you get N is equal to 5.88 and ω_c equal to 0.704 okay. So, you choose N is equal to 6 , nearest integer.

(Refer Slide Time: 27:04)

So, N is equal to 6 will give me the roots placed at an angle of three twenty, three sixty degrees divided by two into six, twelve; so thirty degrees, all right. So even number of roots, if you remember; discussed earlier even number of roots, six roots on this side, so there will not be anything on the real axis. So, at fifteen minus fifty degrees, fifteen plus thirty; forty-five degrees minus forty-five degrees, forty-five plus thirty, seventy-five degrees then again hundred and five, fifteen degrees; hundred and five degrees, hundred and thirty-five degrees and so on.

They just mirror images okay, one two three; so one, two, three, four, five, six, six on this side, six on the other side. So, you can form the polynomials and what is a radius of the circle? It will be point 0.704 ; you know it is the cut of frequency. You know it is normalized against this

ωc ; so this is of radius ωc equal to 0.7×10^4 , all right. So, you know the roots cosine of 15 degrees of this side, cosine of fifteen degrees with a negative sign and sin of 15 degrees and 45 degrees also and so on.

So, the polynomials if you take the pair of roots at a time, you will get $S^2 + 0.365s + 0.495$, after de-normalizing $s^2 + 0.995s + 0.495$ into $S^2 + 1.359s + 0.495$, okay. Now for if you remember; we had earlier discussed, if I have a function $a/(s + a)$, its corresponding discrete domain representation is $1 - e^{-aT}$ into z^{-1} okay, all right.

Then $(s + a)^2 + b^2$, exponentially decaying cosine function corresponding z transform is; $T \int_0^T (1 - e^{-a(t-T)}) \cos(b(t-T)) dt$ into z^{-1} divided by $1 - 2e^{-aT} \cos(bT) + e^{-2aT}$ into z^{-2} plus e^{-aT} into z^{-1} minus twice aT into z^{-1} square, is that all right?

Similarly, $b/(s^2 + a^2 + b^2)$ will give you, $T \int_0^T e^{-a(t-T)} \sin(b(t-T)) dt$ into z^{-1} divided by same denominator all right. So, this we derived earlier. So, will be making use of this; making partial fractions of this $h(s)$ and then making substitution correspondingly. We shall get this as

(Refer Slide Time: 31:17)

The whiteboard shows the following derivation:

$$= \sum_{k=1}^3 \frac{1 - e^{-ak} \cdot \cos bk \cdot z^{-1}}{1 - 2e^{-ak} (\cos bk) z^{-1} + e^{-2ak} z^{-2}}$$

$$= \frac{A_k \cdot (s + a_k)}{(s + a_k)^2 + b_k^2}$$

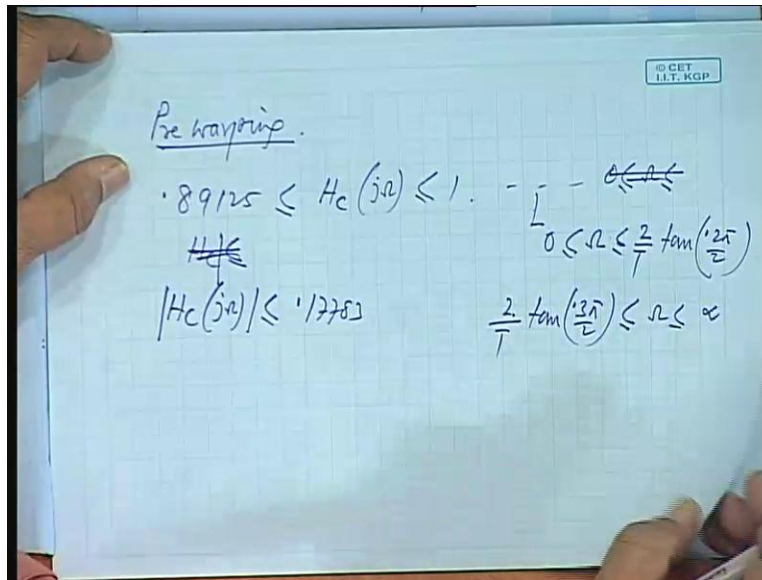

$$= \frac{0.287 - 0.447z^{-1}}{1 - 1.297z^{-1} + 0.695z^{-2}} + \dots$$

1 minus e to the power minus a k cosine b k z inverse divided by 1 minus 2 into e to the power minus a k cosine b k z inverse plus e to the power minus twice a k z to the power minus 2; k varying from 1 to 3 into, this is basically corresponding to S plus a k by S plus a k whole square plus b k square. So, corresponding to this term, this is the expansion.

So in this case in this particular example, we have already got these three factors. So, after doing this kind of partial fraction and simplification; it induces to 0.287 minus 0.447 z inverse divided by 1 minus 1.297 z inverse plus 0.695 z to the power minus 2 plus; three such similar terms I am not going to write all the details, similar terms will appear for the three factors. There are three quadratics, so there will be three such terms.

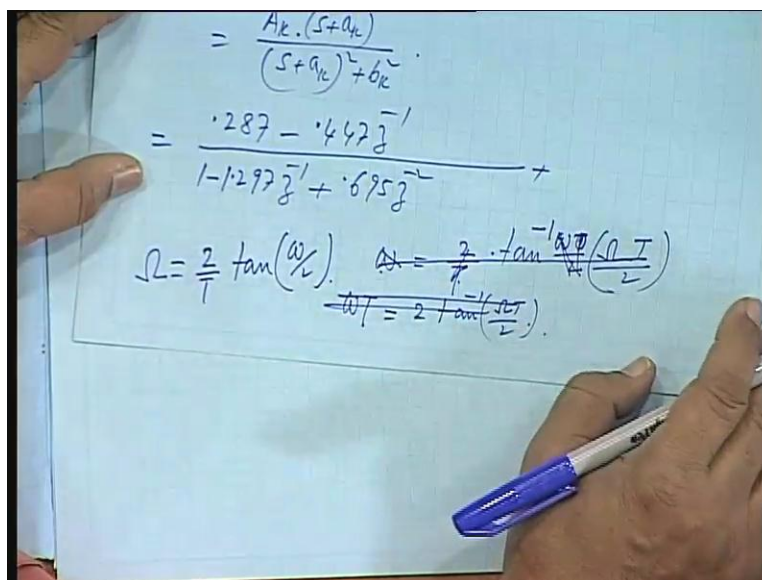

Now, the same problem, if you go for bilinear transformation; let us see what would be the effect. Now in case of bilinear transformation, we need pre-warping, all right.

(Refer Slide Time: 33:25)

So, we change the specification for pre-warping. Let us see, how we do that. The same magnitude 0.89125 should be H in the continuous domain $j\omega$ equal to 1. And H_c ; this is for the pass band 0ω and then what did you get in the bilinear transformation? What was the relation between discrete frequency ω and capital ω , small ω and capital ω ?

(Refer Slide Time: 34:14)

Tangent of omega T by 2, this capital omega into T by 2, is that all right? So, if we normalize if we take T to be 1 then 2 tan inverse, tan inverse or tangent? Are you sure, are you sure? Tan inverse, so omega into T is; omega into T is 2 into tan inverse omega T by 2, you mean this? Are you sure, okay. So, will apply this transformations or you can write omega, omega is equal to; it is the other way, you know.

T is not there. So, it is omega is equal to 2 by T, tangent omega by 2, all right. So, H c so this specification should be 0 omega 2 by T tangent 0.2 pi by 2, is that all right? Because omega is equal to this much, so we are replacing that omega limit of omega by this. Similarly, H c should be magnitude H c should be less than 0.17783 for 2 by T tangent 0.3 pi by 2 omega then this is infinity; earlier it was pi in the discrete domain, in the continuous domain it is infinity.

(Refer Slide Time: 37:30)

Handwritten equations on a grid background:

$$|H_c(j\omega)| \leq 0.17783$$

$$1 + \left[\frac{2 \tan 0.1\pi}{\Omega_c} \right]^{2N} = \frac{1}{(0.891)^2}$$

$$1 + \left[\frac{2 \tan 0.15\pi}{\Omega_c} \right]^{2N} = \frac{1}{(0.178)^2}$$

Frequency limits in the continuous domain:

$$0 \leq \Omega_c \leq \frac{\pi}{T} \tan\left(\frac{2\pi}{2}\right)$$

$$\frac{\pi}{T} \tan\left(\frac{0.3\pi}{2}\right) \leq \Omega_c \leq \infty$$

So, if you use this 1 plus let us convert this into equations, equality equations; 1 plus 2 tan 0.1 pi, this is 0.1 pi by omega c to the power 2 N that should be equal to 1 by 0.891 square, okay. This is s square and the other one is 1 plus 2 tan 0.1 5 pi by omega c to the power 2 N; should be 1 by 0.178 square, is that all right, T you have taken as 1, all right.

(Refer Slide Time: 38:37)

Therefore N , if you solve this two; N comes out to be 5.30466. So, we once again take the nearest integer, N equal to 6. If you substitute in the first equation then ω_c becomes 0.766, okay. Now see, this is ω , this is small ω all right. This is the kind of graph we are getting; as capital ω tends to infinity, this ω tends to $\pi/2$, π sorry, okay.

So, if I have a function specified like this, suppose this is the filter functions specified; these frequencies would be marked here, marked here, marked here, is marked here; so here it is much more compressed. Let me plot it to somewhat like this, sorry. It will be within π because this entire infinite range is compressed within π , so it will be, it will not go beyond this point. So, you can see there is a compression here, okay.

So, that is why while pre-warping, we have expanded this; so that after compression, it takes the normal shape. In any case it will get compressed, so while specifying you stretch it. If you stretch that then it is better to take the first equation. First equation N is more to meet the same same specification, if N is made more that means; ω_c will also be more, this ratio has to be equated to the same constant, N is fixed. So, if you take higher values then this gets stretched, so that that is going to eat the design.

(Refer Slide Time: 42:01)

$$H_c(s) = \frac{0.0238}{(s^2 + 0.396s + 0.5871)(s^2 + 1.083s + 0.5871)(s^2 + 1.4802s + 0.5871)}$$

$$s = \frac{z}{T} \frac{1-z^{-1}}{1+z^{-1}} = \frac{2(1-z^{-1})}{1+z^{-1}} \quad T=1$$

(Refer Slide Time: 43:33)

$$s = \frac{z}{1+z^{-1}} \quad T=1$$

$$H(z) = \frac{0.0407338(1+z^{-1})^6}{(1-1.268z^{-1} + 0.705z^{-2})(1-1.010z^{-1} + 0.358z^{-2})(1-0.903z^{-1} + 0.215z^{-2})}$$

So if you follow, this $H_c(s)$ comes out to be 0.0238 divided by $s^2 + 0.396s + 0.5871$ then $s^2 + 1.083s + 0.5871$ into $s^2 + 1.4802s + 0.5871$, okay. You have got the three factors. Now, you are going to make a direct substitution, there is no partial fraction; unlike the earlier case, here you do not require any partial fraction, no substitution, no transformation in terms of impulse response.

We make a direct substitution; s is equal to $2/T \ln z$ and $1 - z^{-1}$ by $1 + z^{-1}$ and since we have taken normalized T , T equal to 1. So, it will be just $2 \ln z$ by $1 + z^{-1}$, okay. T has been taken to be 1. So, if you substitute that here, you get $H(z)$ which is the discrete filter as $0.0007338 (1 + z^{-1})^6$ divided by; see $1 + z^{-1}$ square square and square, so that gives me it comes in the numerator as to the power 6.

Here in the denominator you get, $1 - 1.268z^{-1} + 0.7051z^{-2}$ into $1 - 1.0106z^{-1} + 0.3583z^{-2}$ into $1 - 0.9044z^{-1} + 0.2155z^{-2}$. So you get three quadratics in z^{-1} I mean z^{-1} and $1 + z^{-1}$ to the power 6 in the numerator. So, the order is 6 in the numerator, 6 in the denominator. So, you require 6 delay elements.

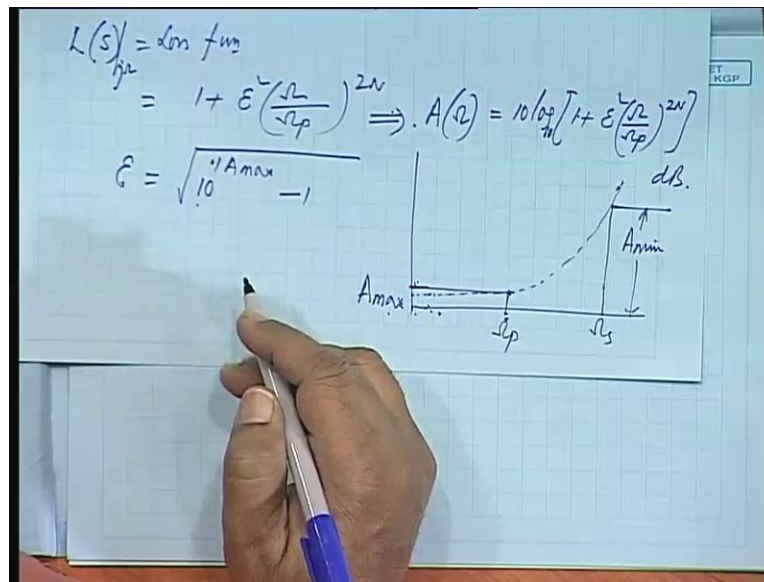

In the other one, in the impulse in variance, how many did you get? How many delay elements are there? There also you got 6, is not? There you have to put all all of them in parallel mode. Sometimes the specifications are given in decibel, decibel gain.

(Refer Slide Time: 45:27)

$$|H(s)|_{s=j\omega}^2 = \frac{1}{1 + \epsilon^2 \left(\frac{\omega}{\omega_p}\right)^{2N}}$$

$$L(s) = \ln f_{dB} = 1 + \epsilon^2 \left(\frac{\omega}{\omega_p}\right)^{2N}$$

(Refer Slide Time: 48:28)

So, we may be given say; $H(s)$ equal to $j\omega$ magnitude as in the pass band, if the specifications are given in the pass band and stop band, we might as well write this in another form. Some people to some people like to take the frequency in terms of ω_p , ω_c is not known. So, we are not going to try to find out ω_c , will straight away take ω_p , okay.

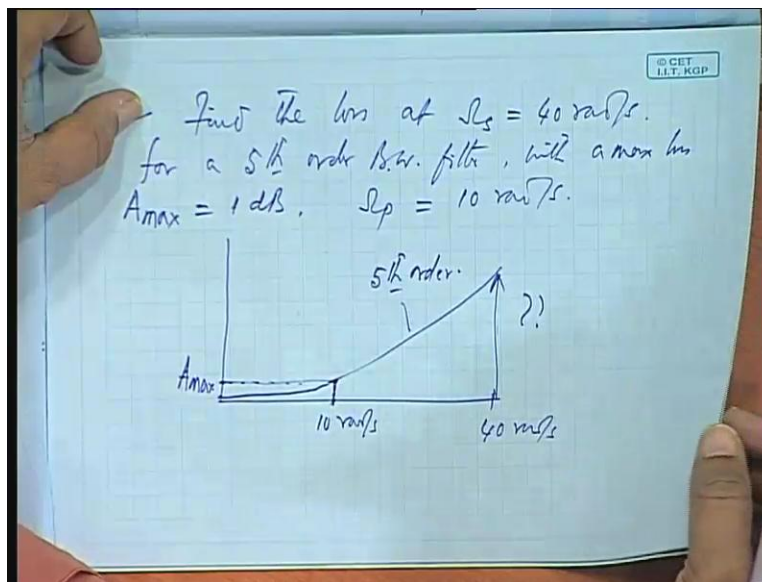

So, we also define a loss function instead of gain, we define loss function. And that may be $1 + \epsilon^2 \left(\frac{\omega}{\omega_p}\right)^{2N}$. Basically, loss means in terms of power; so square of that $1 + H^2$, H is basically output by input signal gain. So, power gain will be H^2 . So, loss will be in terms of in frequency domain s equal to $j\omega$, it will be this much.

So, ϵ is and if this loss is expressed in the logarithmic domain; so $A(\omega)$ will be $10 \log 1 + \epsilon^2 \left(\frac{\omega}{\omega_p}\right)^{2N}$, so many dB's all right. So, the loss function looks like this, I come to this afterwards. Loss function looks like this. Within a certain band this is the pass band; the loss maximum loss that the filter can suffer is specified A_{max} all right, that means the gain should not fall below this point, that means the loss should not be above this.

Similarly in the stop band, we want the loss should be at least this much, it should be above this. So this is A_{\min} . So, A_{\min} is very high and A_{\max} is very very small; mind you A_{\max} is not necessarily greater than A_{\min} , never greater than A_{\min} , A_{\min} means in the pass band, this is the minimum loss, it should have. So, it is a very high value.

So, epsilon if you are given this specification; that in the pass band A_{\max} is the maximum loss then $10 \log_{10} \frac{1}{\epsilon}$ and that would be, epsilon from here itself when ω is equal to ω_p , that will become epsilon square. So, A corresponds to A_{\max} . So, A_{\max} divided by 10, so $0.1 A_{\max}$. If you exponentiate with respect to the base 10, so 10 to the power this minus 1; that gives me epsilon, okay.

(Refer Slide Time: 49:38)

(Refer Slide Time: 51:11)

And let us work out one example. Find the loss, find the loss at omega s equal to 40 radians per second for a fifth order Butterworth filter; with a maximum loss which is A max, with a maximum loss A max equal to 1 d B in the pass band age, this is the pass band age frequency of 10 radians per second. That means, you are given this is 10 radians per second, this is 40 radians per second, this is the maximum loss A max. And you have to determine the loss here. If this is of fifth order Butterworth polynomial, okay.

So, epsilon is root over 10 to the power 0.1 A max minus 1; so that gives me 10 to the power 0.1 and A max is given 1 d b, so 0.1 in to 1 minus 1, is that all right? So, 10 to the power 0.1 is how much? If you take log, 0.1 into log 10 is 1. So, point 1, that is log of 5 minus log of 4 approximately; log of 4 is 0.6, log of 5 is 0.7, so this the difference is 5 by 4 is 1.25. So, 1.25 minus 1.25, so under root of that, approximately 0.5, okay under root of point 0.25.

(Refer Slide Time: 52:09)

$$s = \frac{0.509^{1/5}}{4}$$

$$\epsilon \left(\frac{\omega_s}{\omega_p} \right) \Rightarrow \frac{\omega_s}{\omega_p} = 4$$

$$10 \log [1 + \epsilon^2 \cdot 4^{10}]$$

$$= 10 \log [1 + 0.25 \times 4^{10}]$$

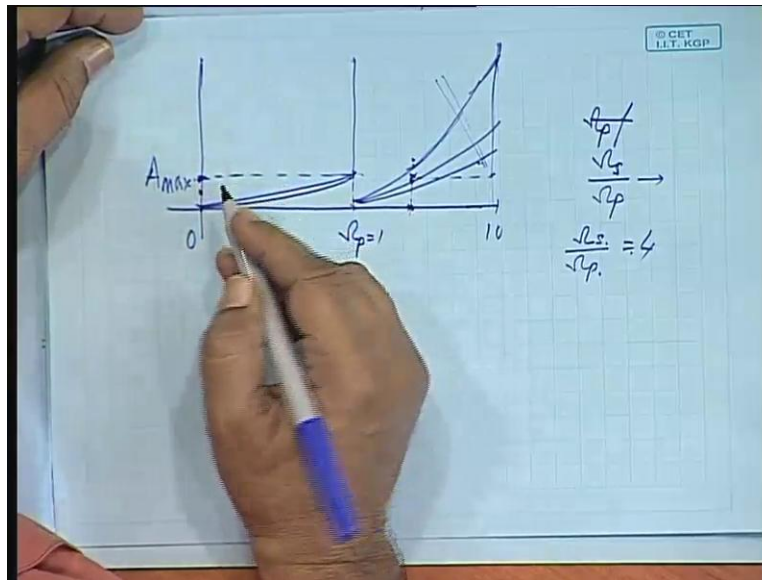

$$\approx 10 \log (0.25 \times 4^{10}) = 10 \log (4^9)$$

$$= 90 \times 0.6 = 54 \text{ dB}$$

So, omega s will be what will be omega s? Stop band frequency? 0.509 to the power 1 by 5 into 4, basically it is epsilon; actually this is 0.5 was an approximation, actual value is 0.509, okay. So, epsilon to the power 1 by N into whatever was that omega s by omega p, omega by omega p, okay; will be no, this will be the normal omega. See, omega s was given as 40 radians okay. 40 radians, we have got epsilon.

So, if you can put in that equation, what was the equation; you can see, the loss function was $10 \log [1 + \epsilon^2 (\omega_s/\omega_p)^{2N}]$, this is not I was calculating something else. So, $1 + \epsilon^2 (\omega_s/\omega_p)^{2N}$, and how much is that; is equal to 4. So, 4 to the power 10, okay. So, that is equal to 10, one can be neglected, 1 plus; and how much is epsilon, square 0.25 into 4 to the power 10. So, that is approximately equal to $10 \log (0.25 \times 4^{10})$, okay. So, I can write 10 into log of 4 to the power 9. So, $90 \log 4$, log 4 is 0.6; so approximately 54 dB okay, okay thank you.

(Refer Slide Time: 55:11)

Now in the design manuals, you may refer to design manuals where for different values of A_{max} in a normalized frequency, ω_p by okay ω_s by ω_p , is known okay. You make a plot of ω_s by ω_p , ω_s by ω_p so ω_p is taken as 1. You have for different orders, N is equal to 1, 2 etcetera; you have such plots and say this is between 0, 0 and 1.

And 1 to 10 makes decade, you have in the stop band you have the plots because ω_s will be given; ω_s by ω_p , suppose the ratio is 4. So, I will go to 4. And for different values of N , as N increases it goes on increasing, all right. So, at N is equal to 4, I can read of that particular stop band $d B$; that is A_{min} , if A_{min} is specified I will just refer to the nearest integer value, okay, I will go to the higher value, next integer.

So, I select N . Once you select N , the polynomials are fixed all right. There are, all of the unit circle, you know the location of the roots; so you can calculate the Butterworth polynomial and even there also available in the table. So, the design is very very simple with the help of such chart for different values of A_{max} .

A max will have to be given; so they give 0.25 d B 1, d B 0.5 d b and so on. So, these are specified and these curves are available; you can always select the particular value of N and design the filter okay. We will stop here for today; will continue with this in the next class. Thank you very much.
