Lecture - 29
Random Signals

(Refer Slide Time: 00:48)

So far we have discussed about discrete systems, which were deterministic in nature; that means, with respect to time, with respect to a particular interval we know the value of the variable to be somewhat exact. Only in the last few classes, when you are talking about quantization error, rounding off error, we talked about noise, which were random in nature. So, random signals are defined in terms of the statistical properties, now they are not periodic, but the statistics will give you some properties, you cannot take Fourier transform or z transform of random signals.

But you can take Fourier transform that is in the frequency domain, you can describe some of the statistical properties like, auto correlation, co variance and so on. Because, these properties are again will show later on they can be also expressed in terms of the time variable or in terms of distinct variable n . So, suppose you have a speech signal, we speak a word we alter different sounds.

So, they are all random in nature, when you say a say b there is a particular signal which is basically a sample of, so many I mean, so many sounds that we make a, b, c, d and b

may be pronounced by different people in different ways. So, there are, so many possible sounds, so many possible signals out of which say when I at a particular sound b, then it is one of those ensemble of those signals, which is the sound b.

Even in the same person when he utters the same sound at two different instant of time, suppose I have got cold, today I may have a little nozzle sound. So, the signal will change, so it is random in nature, there are so many instances of randomness in signals, that it is a very important study to be made. We are not going to the details of random signals, just basic statistical properties we are going to discuss, so let me first take up.

So, speech signal is a random signal, let me defined some of the simple quantities P_x alpha, we define as the probability, that the variable x is less than or equal to alpha P_x alpha we define as a probability of the variable x, x is the random variable, x is less than equal to alpha. We, define actually the probability in terms of a density function, which is small p you write alpha, which is variation of this probability with alpha any question.

Why should it be a partial derivative, it is implicit it may be a variable of time also, though you are not mentioning it here in a situation, when this varies with other variables like time, then it should be partial derivative. So, for a continuous variable x we can write P_x alpha as minus infinity to plus infinity small p x I will write u du, this is alpha, this is minus infinity to alpha.

(Refer Slide Time: 06:17)

$$P_x(\infty) = \int_{-\infty}^{\infty} p_x(u) du = 1.$$
$$P_x(-\infty) = \int_{-\infty}^{-\infty} p_x(u) du = 0.$$
$$0 \leq P_x(\alpha) \leq 1$$

$$0 \leq P_x(\alpha) \leq 1$$
$$r\text{th moment} = \mu_r$$
$$= E[x^r] = \int_{-\infty}^{\infty} \alpha^r \cdot p_x(\alpha) \cdot d\alpha.$$
$$r = +ve \text{ integer.}$$

The value of P_x at infinity will be minus infinity to plus infinity $P_x u d u$ that is the maximum probability, that you can have. And that is equal to 1 and P_x minus infinity will be from minus infinity to minus infinity, so it will be 0. So, $p_x \alpha$ will be varying between 0 and 1 as α changes from minus infinity to plus infinity.

Next we define the r 'th moment, the r 'th moment as μ_r is equal to expected value of x to the power r let me put this bracket, x is the random variable to the power r . So, this will be defined as minus infinity to plus infinity covering the entire range α to the power r $p_x \alpha d \alpha$ this is the running variable α r is any positive integer. So,

when you talk about random variables they are defined in terms of the statistics by that you mean all the moments.

So, the 0th order statistics would be r is equal to 0, if you put α equal to 0 it gives me only the total probability. If I take r is equal to 1, so that will be the mean that is if p_x is equal to 1 p_x is constant then it is a normal arithmetic mean, so it is basically p_x gives you the weight age.

(Refer Slide Time: 09:20)

Mean
 $E(X) = m_x$
 $= \int_{-\infty}^{\infty} \alpha p_x(\alpha) d\alpha$
 $E(X^r) = \int_{-\infty}^{\infty} \alpha^r p_x(\alpha) d\alpha$

$\sigma_x^2 = E[(X - m_x)^2] = E[(X - E(X))^2]$
 $= \int_{-\infty}^{\infty} (\alpha - m_x)^2 p_x(\alpha) d\alpha$

So, weighted mean that is known as the mean, so mean we write as expected value of x , so there are three quantities, the first moment, second moment and mean of the squared

quantity squared variable, these are the three quantities, which define more or less the statistics of a random variable. We can go for higher order statistics also higher order moments, but for most of the practical situations we deal with the mean variance and the mean squared variable. So, this we write as m_x is equal to minus infinity to plus infinity $\int_{-\infty}^{\infty} p(x) dx$ mean of the squared.

And we define variance as expected value of $(x - m_x)^2$ that is expected value of x minus expected value of x . So, square of this I will put another bracket, so square this and what will be this minus infinity to plus infinity. Say if we take the running variable $\int_{-\infty}^{\infty} (x - m_x)^2 p(x) dx$, I have a very bad habit writing infinity and alpha more or less that the same symbol this is infinity and this is alpha, the limits are minus infinity to plus infinity.

(Refer Slide Time: 12:19)

So, σ_x^2 if you expand this will be at σ_x^2 as expected value of x^2 minus m_x^2 and σ_x we call standard deviation. Now, this is very important whenever there is a particular distribution given say distribution of marks, we talk in terms of the dispersion σ_x . How much is the variable changing, in which range it is changing and how is it distributed, you can have a the range similar.

Suppose, the performance of students in a particular class, there may be two subjects, where in one case the dispersion is high, that is the distribution of marks may be like this in this is a mean value around the mean value, in the other case. And suppose the range

is only up to this, in the other case like this both of them are bell shaped having same range, same mean value, but the distribution is different. So, here sigma is more this sigma 2, this more than sigma 1 from the nature of the characteristics, you can find out.

Suppose, a random variable will take a simple example, a random variable has a probability density function given as $p_x(\alpha) = 1 - \frac{\alpha}{2}$ for $0 \leq \alpha \leq 2$ and equal to 0 otherwise, what is the nature of this function, it will be a straight line like this. So, this is the random variable x and this is the PDF. Now let us compute the three quantities, the first moment, second moment and the variance.

(Refer Slide Time: 15:34)

$$M_x =$$

$$P_x(\alpha) = \int_{-\infty}^{\alpha} p_x(u) du$$

$$= \int_{-\infty}^{\alpha} \left(1 - \frac{u}{2}\right) du = \alpha - \frac{\alpha^2}{4}$$

$$\text{Prob.} [0.6 \leq x \leq 1.2]$$

$$= P_x(\alpha_1) - P_x(\alpha_2)$$

$$= \left[1.2 - \frac{(1.2)^2}{4}\right] - \left[0.6 - \frac{(0.6)^2}{4}\right]$$

What will be the first moment could you check that is m_x , what is the probability $P_x(\alpha)$ to α , what is the dependence of this with respect to x that is this is the density function given. ((Refer Time: 16:07)) So, what is the probability, probability means area under the curve from minus infinity to that one, from minus infinity to this 0 it is all 0. So, you have to take only in this area and at x what is that capital P_x it will be only this area, so can I write in terms of that variable x .

So, we are writing this as α , so it will be p_x say du which will be $1 - u/2$ by du integrated from minus infinity to plus α is it all right. So, it will be $\alpha - \alpha^2/4$ is that I am just taking u as the running variable, so $\alpha - \alpha^2/4$. So, $0 \leq \alpha \leq 2$, so at $\alpha = 0$ it is 0, it is the area is increasing and

may be somewhat like this I do not know, that you have to compute it will be like this or may be like this, you have to check up you have to plot this.

What will be the probability that this lies between say 0.6 and say 1.2 what is the probability, this is the density function given what is the probability that x lies between 0.6 and 1.2. So, just I can write $P(x < \alpha_1) - P(x < \alpha_2)$, where this is α_2 , this is α_1 , so $P(x < \alpha_1)$ is this area, $P(x < \alpha_2)$ is this area, so the probability that it lies between 0.6 and 1.2 is this I mean area under this. So, it will be $1.2 - 0.6$ minus 0.6 squared by 4 minus 0.6 minus 0.6 squared by 4 .

(Refer Slide Time: 19:34)

Handwritten mathematical derivation on a blue notepad:

$$= 0.33.$$

$$m_x = \int_0^2 \alpha \left(1 - \frac{\alpha}{2}\right) d\alpha.$$

$$= \left. \frac{\alpha^2}{2} - \frac{\alpha^3}{6} \right|_0^2 = 2 - \frac{8}{6} = \frac{4}{3}$$

$$E(x^2) = \int_0^2 \alpha^2 \left(1 - \frac{\alpha}{2}\right) d\alpha = \frac{2}{3}.$$

Handwritten mathematical derivation on a blue notepad:

$$= \frac{\alpha^2}{2} - \frac{\alpha^3}{6} \Big|_0^2 = 2 - \frac{8}{6} = \frac{4}{3}$$

$$E(x^2) = \int_0^2 \alpha^2 \left(1 - \frac{\alpha}{2}\right) d\alpha = \frac{2}{3}.$$

$$\sigma_x^2 = E(x^2) - m_x^2 = \frac{2}{3} - \frac{16}{9} = \frac{2}{9}.$$

Diagram of a uniform distribution on the interval $[a, b]$:

$$p_x(\alpha) = \begin{cases} \frac{1}{b-a} & \dots a \leq \alpha \leq b \\ 0 & \text{otherwise.} \end{cases}$$

So, that gives me correct me if it is all right $m \times$ what is the mean value of this distribution. So, a 0 to 2 minus infinity to plus infinity will be now reduce 0 to 2 alpha into $1 - \alpha$ by $2 d\alpha$ is that all right, the variable and this is the distribution. So, it is α^2 by 2 minus α^3 by 6 0 to 2 we are not computing the earlier, so $2 - 8$ by 6 that gives me $2/3$, what is the expected value of the squared variable same, so that also comes out as $2/3$.

Now, let us compute the variance, so it will be $2/3 - (2/3)^2 = 4/9$, so it is $2/9$ quite often we come across a probability density function, which is uniform. If you remember, we are seeing the quantization error, so it may be say from a to b range may be specified. So, the density function can be written as $1/(b - a)$ when it is lying between a and b and equal to 0 otherwise.

(Refer Slide Time: 22:20)

$$m_x = \frac{1}{b-a} \int_a^b \alpha \, d\alpha = \frac{b+a}{2}$$
$$E(x^2) = \frac{1}{b-a} \int_a^b \alpha^2 \, d\alpha = \frac{b^3 + a^3 + 3ab}{3}$$
$$\sigma_x^2 = \frac{(b-a)^3}{12}$$

$$E(x^2) = \frac{1}{b-a} \int_a^b \alpha^2 \, d\alpha = \frac{b^3 + a^3 + 3ab}{3}$$
$$\sigma_x^2 = \frac{(b-a)^2}{12}$$

What would be the average or the mean it will be $\frac{1}{b-a} \int_a^b \alpha \, d\alpha$ is this all right, see this is the probability density function, which is constant. So, α into $\frac{1}{b-a} \int_a^b \alpha \, d\alpha$, so that $\frac{1}{b-a}$ I have taken out, that is $\int_a^b \alpha^2 \, d\alpha$ and if you take the limits. Then common factor $b-a$ goes out, what is expected value of x^2 again $\frac{1}{b-a} \int_a^b \alpha^2 \, d\alpha$, so it will be $\frac{b^3 - a^3}{3(b-a)}$, so $b-a$ will get cancelled, so it will be $\frac{b^2 + a^2 + ab}{3}$.

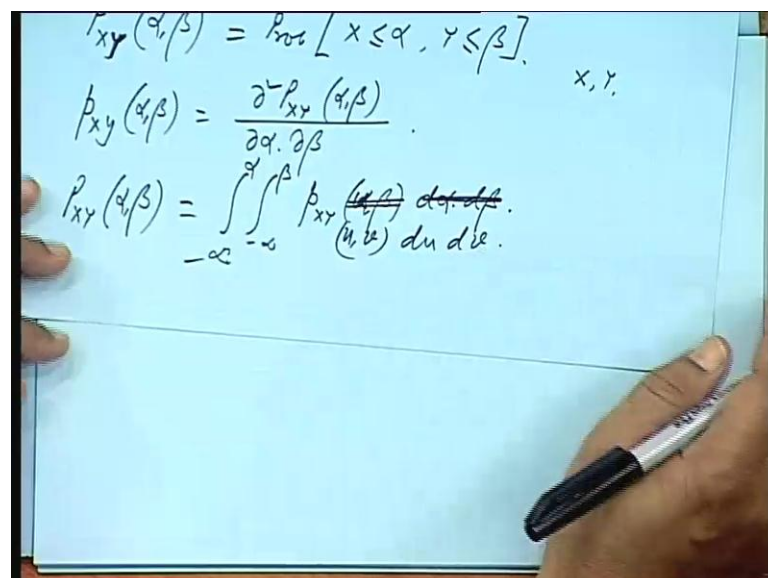

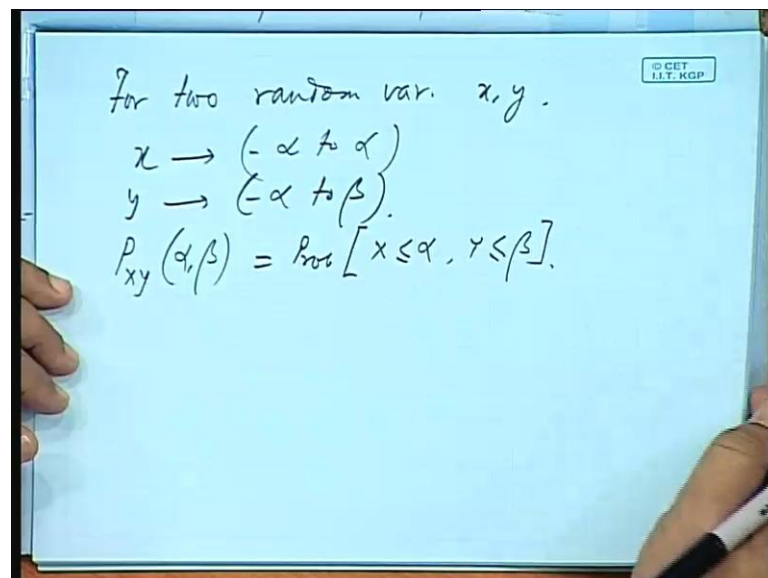

So, it will be σ_x^2 , so you have computed for two typical distributions. One was a distribution like this, the other one is a distribution like this, compute all these

three for a probability distribution, say minus 2 to plus 2 the area will be equal to 1. So, correspondingly you calculate the height 1 by 2, 1 by 2 half base into altitude that will be the area, so base is 4 half into 4 into height, so height will be 1 by 2. So, once you know this you know this we can find out the equation of the line and from there.

Student: ((Refer Time: 25:09))

This one, yes thank you very much all right, so this one you know, so you can find out the equation of the lines. And hence you can compute all the three quantities, the integrations for different a moments, try this is as an assignment.

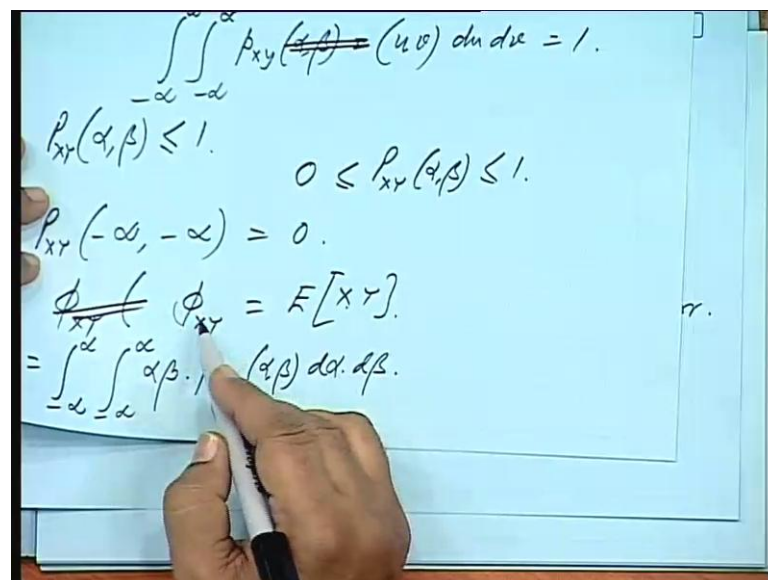

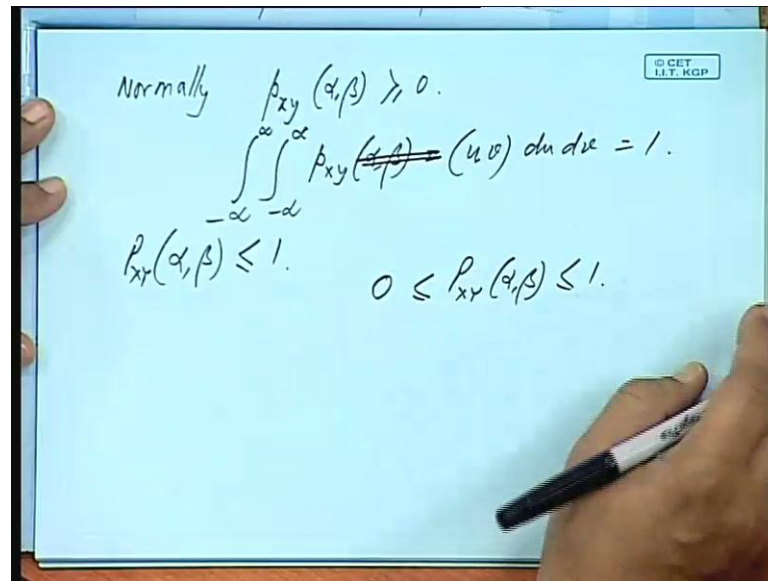

(Refer Slide Time: 25:42)

For two random variables x and y , we study their joint statistical property, in terms of the joint probability density function. There of practical interest quite often we find signals, which are either correlated or at least which are now whose properties are to be computed in a joint manner. So, suppose x is the variable which takes the values from minus infinity to α and y is a variable, which takes the value between minus infinity and β , then probability $x \leq \alpha, y \leq \beta$ is the probability that x is less than equal to α and y is less than equal to β . In many books you will find random variables are written as capital X and capital Y .

So, hence forth I will be using capital X and capital Y and the joint probability density function is defined as the partial derivative with respect to α and β . So, the probability $p(x, y)$ will be basically minus infinity to α minus infinity to β , α β we should not have the running variable same as the limits. So, let me put it as u and v and this is $du dv$.

(Refer Slide Time: 28:38)

So, when you are considering the joint probability density function normally this distribution or this density and minus infinity to plus infinity for both the variables will be always equal to 1 again the same slip u and v should write d u d v equal to 1, anyway it was not alpha. So, I could have put alpha, beta p x y alpha, beta is always less than equal to 1, so the value of the total probability will between 0 and 1 minus infinity and minus infinity it will be 0.

Now, you define cross correlation between two variables x and y, cross correlation of x and y you define as expected value of x and y, which is between minus infinity to plus infinity alpha, beta p x y alpha, beta d alpha, d beta. That means, you take the product of

x and y at all possible values of alpha, beta and then take their average expected value means basically average.

(Refer Slide Time: 31:07)

Handwritten mathematical derivation on a blue board:

$$\begin{aligned} \gamma_{XY} &= E[(X - m_x)(Y - m_y)] \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - m_x)(y - m_y) \cancel{d\alpha d\beta} p_{XY}(\alpha, \beta) d\alpha d\beta \end{aligned}$$

Handwritten mathematical derivation on a blue board:

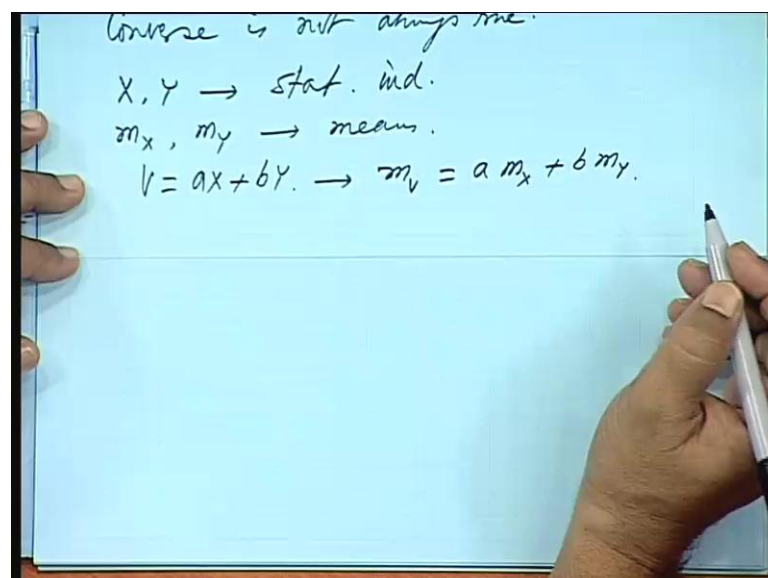

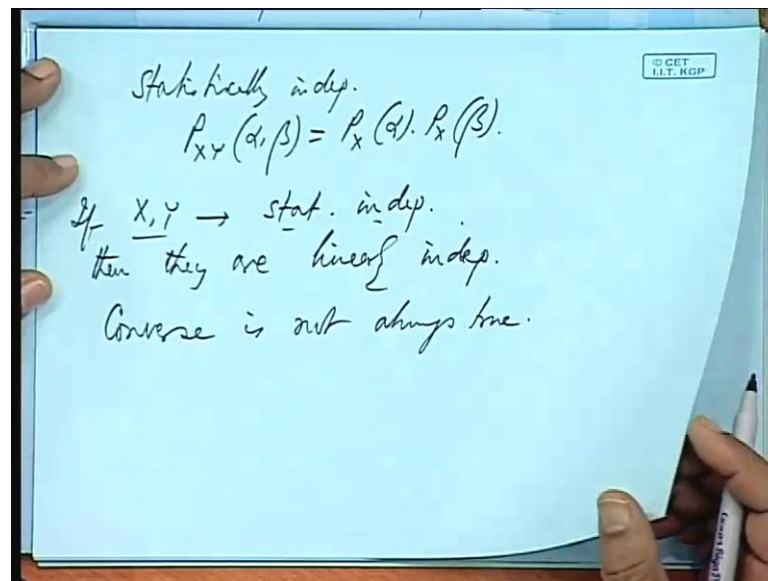

$$\begin{aligned} &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - m_x)(y - m_y) \cancel{d\alpha d\beta} p_{XY}(\alpha, \beta) d\alpha d\beta \\ &= \phi_{XY} = m_x \cdot m_y \end{aligned}$$

~~So~~ X, Y are linearly independent or uncorrelated
 $E(XY) = E(X) \cdot E(Y)$
 i.e. $\gamma_{XY} = 0$.

So, similarly, gamma x y is equal to expected value of x minus m x and y minus m y that is minus infinity to plus infinity alpha minus m x into beta minus m y d alpha into the probability p x y alpha beta d alpha d beta is that all right? Equal to phi x y minus m x m y I phi x y did we not define it yes, phi x y was expected value of x y. So, it will be like this, the variables x and y I linearly independent or uncorrelated if you find expected value of x y is equal to expected value of x in to expected value of y, what is expected value of x y is phi x y and what is expected value of x m x m y.

So, if ϕ_{xy} is equal to $m_x m_y$; that means, this will be 0 that is γ_{xy} is equal to 0. So, if γ_{xy} equal to 0, then if they are linearly independent or uncorrelated, quite often we try to find out if there is any correlation between two signals. Suppose, there is a random signal noise for example, a random noise when you try to find out the correlation of a random noise with any other signal it is always equal to 0; that means, they are two independent variables.

(Refer Slide Time: 34:59)

There are statistically independent if p_{xy} is equal to p_x into p_y , so it can be shown that if x and y are statistically independent, then they are also linearly independent. The reverse is not necessarily true, if x and y are statistically independent,

then they are linear independent, converse is not always true I leave it as an exercise try to prove if not the second one at least the first one.

So, if they are statistical independent if x and y are statistical independent it is easier to derive the statistical characteristics. Suppose, x and y are statistical independent variables with m_x and m_y as their means, then the variable v is equal to a x plus b y, a x plus b y is another random variable, it will have mean as say m_v will be a times m_x plus b times m_y can you prove it.

(Refer Slide Time: 37:34)

$$m_v = E(ax + by)$$

$$= E(ax) + E(by)$$

$$= a m_x + b m_y$$

$$\sigma_v^2 = a^2 \sigma_x^2 + b^2 \sigma_y^2$$

$$\beta_{xy}(\alpha, \beta) = A$$

$$= 0 \text{ otherwise}$$

$-1 \leq \alpha \leq 1$
 $0 \leq \beta \leq 1$

The diagram shows a coordinate system with a horizontal axis labeled α and a vertical axis labeled β . A shaded rectangular region is drawn in the first quadrant, bounded by $\alpha = 0$, $\beta = 0$, $\alpha = 1$, and $\beta = 1$. A point is marked at the origin (0,0).

So, what will be mean of v.

Student: ((Refer Time: 37:41))

Expectation of a x plus b y since they are statistical independent, so expectation of, so a times m_x plus b times m_y , sigma v squared what will be the variance of the variable v is this precisely you calculate, when there is a mixture of say sinusoids, we talking in terms of the RMS value, RMS value. If when you compute it is the RMS value of the first component, square it multiply by the square of the weight age. Similarly, RMS value of the second quantity square it plus multiply by the weight age and so on.

And then take the under root of the entire sum we get the RMS value of the overall variable, when it is a mixture of say 2, 3 sinusoids you compute the RMS value in a similar fashion. Now, let us take a problem, suppose we have p x y as equal to A the

range of alpha and beta, this given like this that is alpha if you write alpha it is between minus 1 and plus 1. And if I write beta, in the alpha beta plane I am just showing the variables it is between 0 and 1.

So, this is the range of alpha and beta, alpha and beta will be this set of points determine the and equal to 0 otherwise. So, the probability density function is if I take an alpha, beta plane and if the height represents the probability density function, then it is a it is like a rectangular cake know a just a brick. So, it is equal to a it is uniform for all the points of alpha and beta, the range is specified and it equal to 0 otherwise, say in this side it is all 0 what is the value of a.

Student: ((Refer Time: 41:07))

Very good, so what is a total area 2, 2 multiplied by a is the total volume and that is equal to one that is good.

(Refer Slide Time: 41:33)

The image shows a whiteboard with handwritten mathematical work. A hand is pointing to the first equation, and another hand is holding a marker near the second equation.

$$A = \frac{1}{2}$$

$$\int_{-1}^1 \int_0^1 A \cdot d\alpha \cdot d\beta = 2A \cdot = 1.$$

$$A = \frac{1}{2}$$

Prob. = $P_{xy} [0.5 \leq x \leq 1, 0 \leq y \leq 0.5]$

$$\dots = 0.25 \times A = 0.125$$

So, A is equal to half if you go by that integration relation it is between minus 1 and plus 1 and between 0 and 1 A d alpha d beta, the PDF is a and that is equal to 2 A and that should be equal to 1 total probability therefore, A is equal to half. So, compute the probability p x y, x lying between 0.5 and 1, y lying between 0 and 0.5, so what would be the value 0.5 and 1. ((Refer Time: 43:02)) So, once again A is between 0.5 and 1 and b is between 0 and 0.5 0 and 0.5, so is this small rectangular piece into A is not into A

height is A. So, this is 0.5 and this is also 0.5 0 to 0.5 y is between 0 to 0.5, so 0.5 into 0.5 0.25 into A. So, the total probability will be 0.25 into A that is 0.125 that is the volume of the brick for a discrete signal.

(Refer Slide Time: 44:09)

For a discrete signal is

$$m_{x[n]} = E\{x[n]\} = \int_{-\infty}^{\infty} \alpha p_{x[n]}(\alpha, n) d\alpha.$$

$$E\{x[n]\} = \int_{-\infty}^{\infty} \alpha p_{x[n]}(\alpha, n) d\alpha.$$

$$\text{Var. } \sigma_{x[n]}^2 = E\{x[n] - m_{x[n]}\}^2.$$

$$E\{x[n]\} = \int_{-\infty}^{\infty} \alpha p_{x[n]}(\alpha, n) d\alpha.$$

$$\text{Var. } \sigma_{x[n]}^2 = E\{x[n] - m_{x[n]}\}^2.$$

$$= E\{x[n]\} - (m_{x[n]})^2$$

We write the mean as expected value of x n, let me put once again the first bracket, so that is minus infinity to plus infinity, in the discrete domain will put summation. So, expected value of x n how do you put that.

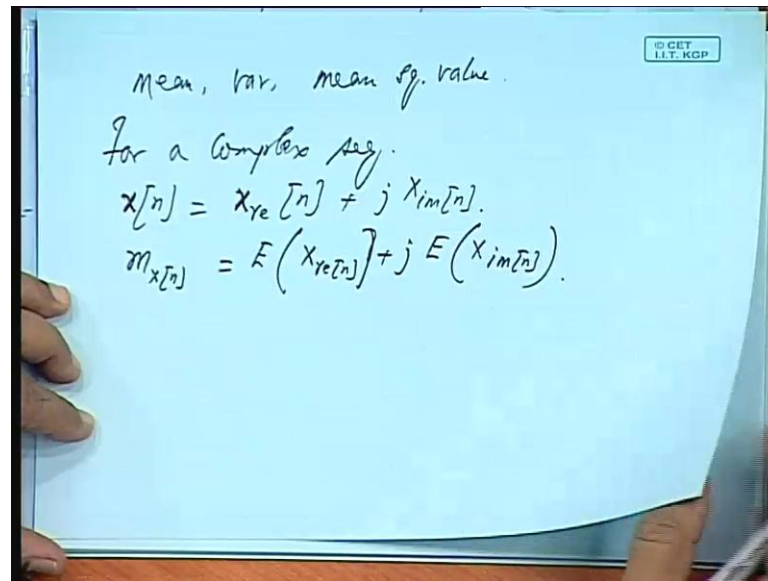

Student: ((Refer Time: 45:00))

Now, in the beginning itself I had mentioned about the speech signal, we are taking discrete domain of time, but we are considering at any moment there can be, so many possibilities at any moment there are, so many possible values. So, it is one of those values, what is the probability that at this moment the say sound will be like this, what are the possible values of the sound.

So, it is in the discrete domain of time is it all right we are not varying n at any instant of time n , what are the possible combinations, what are the possible values of x_n . So, it will be minus infinity to plus infinity, this is the range of x at any instant of time $\alpha \leq x_n \leq \alpha + \Delta$. Actually, we are in the habit of taking mean with respect to time not the mean at a particular instant of all the possible values of that variable at a particular instant, if that mean is same as the other mean, then it is definitely a stationary process it is an ergodic process.

So, expected value of x_n^2 will be minus infinity to plus infinity $\alpha^2 \leq x_n \leq \alpha + \Delta$, if you want to calculate for all possible times then only the summation comes, I am not summing over n it is integrated over α . So, variance it will be expected value of x_n^2 minus $(\text{expected value of } x_n)^2$ after using the third bracket, so often I am use to it. So, I have forgotten about the first bracket that is equal to expected value of x_n^2 minus $(\text{expected value of } x_n)^2$.

(Refer Slide Time: 49:12)

Now, mean variance and the mean squared value mean of the squared value, these are function of n is it not; that means, they can change with time. So, if a process does not have a constant value; that means, does not have a value which is independent of n , then it is not a stationary process, when it remains constant with respect to n , then it is a stationary process.

We call it strictly stationary process, if all other moments higher order moments are also remaining stationary; that means, they are constant they are not changing with n . So, say when we speak for example, in a speech signal when I make a sound for some time you

will find it is having a particular average, particular variance. Then I change the word, I mean I change the sound I switch over to another sound, then again the mean changes.

So, it is a constantly changing mean, variance and other moments for a complex sequence we write $x_n = x_{\text{real } n} + j \text{ times } x_{\text{imaginary } n}$. So, mean of this will be expected value of $x_{\text{real } n} + j \text{ times expected value of } x_{\text{imaginary } n}$, so you segregate the real and imaginary parts in terms of the means. Similarly, variance will find expected value of $x_n - m$ and when you take magnitude square we will get expected value of $|x_n - m|^2$. Actually it is immaterial, you need not put a bracket you can expand and then see for yourself x_n , you put here and then see.

Sometimes we are interested in the statistical relation between two quantities in the time domain or; that means, at two different instance how are they related x at this moment, y at the other moment or x at this moment and x at the other moment. So, when we are talking about the two different instances x and y their cross correlations of different time span when they are with a same variable, then they are auto correlation.

So, these are two important quantities now depending on the nature of variation of these with respect to the time span the time range, if you can express them and if the statistical properties are definite, then we can take their Fourier transform. So, we can take transforms not of the original signal, but they are properties, original signals x and y it will be difficult to take transforms, but if you take their auto correlation or cross correlation, you can take their transforms. So, this is one very important property I do not think will be able to take up any example, will take it up in tutorial classes in a little more detail about the transforms and other relations if time permits.

(Refer Slide Time: 54:47)

$$x[n] = A \cos(\omega_0 n + \phi).$$
$$p_A(\alpha) = \begin{cases} \frac{1}{4} & 0 \leq \alpha \leq 4. \\ 0 & \text{otherwise.} \end{cases}$$
$$p_\phi(\beta) = \begin{cases} \frac{1}{2\pi} & 0 \leq \beta \leq 2\pi \\ 0 & \text{otherwise.} \end{cases}$$
$$p_A(\alpha, \beta) = \begin{cases} \frac{1}{8\pi} & 0 \leq \alpha \leq 4, 0 \leq \beta \leq 2\pi \\ 0 & \text{otherwise} \end{cases}$$

Let us take a simple example, $A \cos(\omega_0 n + \phi)$, the probability distribution of this amplitude, you say $1/4$ and is equal to 0 otherwise. Similarly, for this phase ϕ we have $1/2\pi$ and 0 , this is between β is between 0 and 2π equal to 0 otherwise. That means, the phase difference can vary between 0 and 2π and the magnitude can vary between 0 and 4 , so what would be the statistical properties of this.

So, p_A that joint probability density function will be $1/4$ in to $1/2\pi$, so $1/8\pi$ in the range this $0 \leq \alpha \leq 4$, $0 \leq \beta \leq 2\pi$ and equal to 0 otherwise it is a constant. So, you can calculate m_x n_x n_x is this, so it is having dependence on two random variables α and ϕ .

(Refer Slide Time: 57:07)

$$\int_0^{2\pi} \int_0^{2\pi} \cos(\omega_0 n + \alpha) \cos(\omega_0 n + \beta) d\alpha d\beta$$

$$= 0.$$

$$E(x^2) = \frac{8}{3}.$$

$$\phi_{xx}[m, n] = \frac{8}{3} \cdot \cos[\omega_0(m-n)].$$

So, what is the average value of this what is the mean 1 by 8 pi 0 to 4, 0 to 2 pi then the variables α and β will write as a running variable α and β . So, $\alpha \cos(\omega_0 n + \alpha)$ $\beta \cos(\omega_0 n + \beta)$, so if you complete this you I leave it as an exercise, you complete this integration it will be 0, two sinusoidal quantities separated by 2π . Similarly, you also compute expected value of x squared you work it out find out the value.

And then autocorrelation, if I take an autocorrelation of lag m and n there are two variables is it not α and β magnitude and phase. So, there are two variables same may done, I am just giving the result check up whether you are getting this, so autocorrelation of two variables, means in both m and n you can take two dimensional transforms, autocorrelation of one dimension you can always take one dimensional transform. So, we will stop here for today, I will take up some problems in the tutorial class.

Thank you very much.
