

Estimation of Signals and Systems
Prof. S. Mukhopadhyay
Department of Electrical Engineering
Indian Institute of Technology, Kharagpur

Lecture - 19
Kalman Filter – Derivation Contd.

From where we left yesterday, so what did we find yesterday? Yesterday we had seen, basically two steps to remember that; we first solved the least square problem and found a solution, then we which is the which was the weighted least square problem, in which we choose some weight matrix W . Then we found then then from among that solutions we we found that, if we choose W is equal to some R^{-1} , then we we find that the variance of the states is minimized, right.

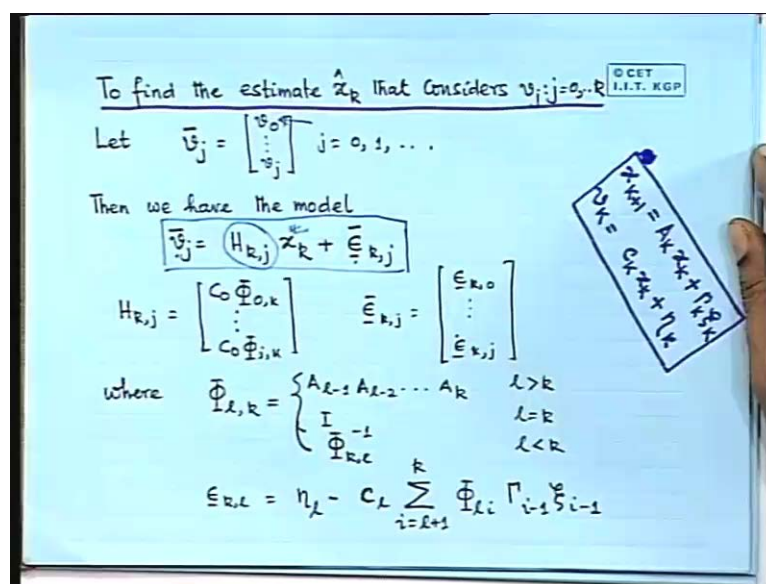

(Refer Slide Time: 01:33)

We did this for a single measurement v , now remember that; even if it is a single measurement, firstly remember that it is a vector and in our treatment, nowhere we it is for a general vector v . It is so happen that, it it it was v_k but we can do it with respect to any other vector. The analysis are as such did not assume anything, it just found simple least square solutions, may yes to a linear vector optimization problem, nothing else.

So the idea is that, if we want to do the same thing with respect to all the measurements from v_0 to v_k , then all we have to do is that, we have to formulate a similar estimation problem involving measurements from v_0 to v_k . Exactly a similar linear vector measurement problem, and then solve it in the exactly the same manner. So that is what what we are going to do today, okay. So first thing, that we are doing, now previously we had found out \hat{x}_k , that consider only v_k in the last days notes class.

(Refer Slide Time: 02:54)

Now we have we have we will find an estimate, which will not consider only v_k but we will consider all v_k , v_k from v_0 to v_k , right. So that is why we will solve a least square problem, which will minimize the weighted sum of all these errors and then be be be minimum variance. So now first of all we have to write the system equations in a, previously what was our equation? Our equation was v_k is equal to $C_k x_k$ plus $x_i k$. So v_k so the left hand side the is is the measurement vector, then a matrix C_k multiplied by the thing that we want to optimize x_k ; you want to optimize an estimate of x_k plus some noise term, this was our form.

So first of all when we consider so many measurements, you have to again pose the problem in that form, first. So so now how do you, so it it turns out that; if you write this v , you remember that in initially in the last class, we did it with respect to a single element. Now we

are cascading all the element, these may be individually these may be vectors. So we are putting one vector, then the next vector, then the next vector; we are making a long vector, okay. Now how do we now first of all we have to write our, to be able to utilize our last days results; we have to cast the problem in such a form, where we will have the measurement on the left hand side as a vector, then we will have some matrix, multiplied by the quantity, that we want to estimate plus some some a vector, you have to first put it in this form.

So so how do you put it in this form? So we apply the normal state transitions rules; that is what we are trying to say is that, we can always write that let us say, we can always write like this. That is what is the state transition relationship? Say our equation is, what is our equation? Our equation is this v is the, in this case this v is the, one second our equation is like this, x_k plus one is equal to $A_k x_k$ plus γ_k , x_i, k , okay. So if it is like that, then then you can you now now and finally; we have v_k is equal to $C_k x_k$ plus η_k , this is our system model, okay.

So now what we have to write is that, we have to cast we have have to express these in terms of in this form. How do you do that? This is again a kind of algebra, where so what we are what we are writing is, this is you know this is a kind of symbolic form. This what does it say? It says that, I have difficulty in writing, it says that v zero for example, let let's take the first term; first term is v_0 , right.

(Refer Slide Time: 07:23)

Handwritten mathematical derivations on a blue background, showing state transition equations and Kalman filter equations. The equations are:

$$z_1 = A_0 z_0 + \Gamma_0 \xi_0$$

$$z_2 = A_1 [A_0 z_0 + \Gamma_0 \xi_0] + \Gamma_1 \xi_1$$

$$z_0 = [A_1 A_0]^{-1} z_2 - A_1 \Gamma_0 \xi_0 - \Gamma_1 \xi_1 = \tilde{A}_1 \tilde{A}_0 z_0$$

$$\begin{bmatrix} v_0 \\ v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} C_0 [A_1 A_0]^{-1} z_2 - C_0 A_1 \Gamma_0 \xi_0 - C_0 \Gamma_1 \xi_1 \\ C_0 z_2 + \eta_2 \end{bmatrix}$$

$$E_{z,t} = \eta_t$$

v_0 is equal to what? v_0 is equal to c_0, x_0 plus η_0 , okay. Now if we have if if we have a concept of a state transition matrix, then we have what do we have? That is how do we write, x_k in terms of how do we write x_k in terms of x_0 ? For example, we write x_1 is equal to x_0 is equal to ϕ is equal to $A_0 x_0$ plus $\gamma_0 \xi_0$. Then we write x_2 is equal to $A_1 A_0 x_0$, x_2 is equal to A_1, x_1 plus γ_1, ξ_1 , right. So in other words, if you if you go on doing it like this you will get that, you will get x_2, x_k is equal to what? One second, you will get, right, correct. So you will get x_2 minus A_1 , let us get x_2 from x_0 ; just let us put k is equal to two to understand. So we are getting x_2 minus A_1, γ_0, ξ_0 minus γ_1, ξ_1 is equal to $A_1 A_0 x_0$, correct.

Now how do we get x_0 ? What do we have to get? We have to we will get this one from x_k , remember that we are estimating x, x at at time instant k , but we have to relate it to the measurement at zero; we are going we have to go back, okay. So so so now here is an assumption, that all these matrices are invertible; this we are assuming again as I said right in the beginning, that we have to assume certain things. So what we will this be? This will be A_1, A_0 inverse x_2 minus A_1, A_0 inverse, $A_1 \gamma_0, \xi_0$ minus $\gamma_1 \xi_1$, correct. So now what is A_1, A_0 ? Now you can say that, $A_1 A_0$ is a now you see that; so you see that, x_0 is equal to this. So what is v_0 ? So v_0 , I put this x_0 here. So I will get C_0, A_1, A_0 inverse x_2 minus $A_1 C_0 A_1 A_0$ inverse $A_1 \gamma_0 \xi_0$. Now A_1, A_0 inverse means; A_0 inverse, A_1 inverse A_1 inverse into A_1 will get cancel.

So actually this term will be $C_0, A_0 \gamma_0 \xi_0$ minus C_0 ; this will be A_1, A_0 inverse $\gamma_1 \xi_1$, correct. This is so now you see that, if you if your k is 2, then you have expressed v_0 in terms of x_2 and the noises ξ_0 and ξ_1 , correct. Similarly, you can write v_1 , similarly you can write v_2 . So if you now now you can form a vector v_0, v_1, v_2 and everywhere, you are you are going back to x_2 . So in this case what will will be? It will be C_0, A_1 inverse x_2 minus, C_0, A_1 inverse γ_1, ξ_1 . This will be what? This will be C_0, x_2 , there is v_0 is plus η_0 is there, if you write v_0 , you have to write plus η_0 . So plus η_1 plus η_2 , because of this term. So you see that you can it it is now possible; now now now you can now, this becomes your h matrix. So it is h into x_2 , plus some term which is a linear sum of the process noise components and the measurement noise, right.

So these terms these terms, I have made an this is the basic idea. So now therefore, these terms can be expressed in this form, you see what is this H k j matrix?

(Refer Slide Time: 13:27)

$$x_0 = [A_1 A_0]^{-1} x_2 - A_1 A_0^{-1} [A_1 \Gamma_0 \xi_0 - \Gamma_1 \xi_1]$$

$$\begin{bmatrix} x_0 \\ x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} C_0 [A_1 A_0]^{-1} \\ C_0 A_1^{-1} \\ C_0 \end{bmatrix} x_2 - \begin{bmatrix} C_0 A_1^{-1} \Gamma_1 \xi_1 \\ C_0 \Gamma_1 \xi_1 \end{bmatrix} + \begin{bmatrix} C_0 A_0 \Gamma_0 \xi_0 \\ C_0 (A_1 A_0)^{-1} \Gamma_1 \xi_1 \end{bmatrix}$$

$$x_1 = C_0 A_1^{-1} x_2 - C_0 A_1^{-1} \Gamma_1 \xi_1 + \eta_1$$

$$x_2 = C_0 x_2 + \eta_2$$

$$H_{k,j} = \begin{bmatrix} C_0 \Phi_{0,k} \\ \vdots \\ C_0 \Phi_{j,k} \end{bmatrix} \quad \bar{E}_{k,j} = \begin{bmatrix} E_{k,0} \\ \vdots \\ E_{k,j} \end{bmatrix}$$

where $\Phi_{l,k} = \begin{cases} A_{l-1} A_{l-2} \dots A_k & l > k \\ I & l = k \\ \Phi_{l,k}^{-1} & l < k \end{cases}$

$$E_{k,L} = \eta_L - C_L \sum_{i=L+1}^k \Phi_{L,i} \Gamma_{i-1} \xi_{i-1}$$

It is $c_0, \phi_{0,k}$. So what is $\phi_{0,k}$? $\phi_{l,k}$ has been defined as from A_k to A_{l-1} where l is greater than k . Now in this case A is less than k , because it is $0_k, k$ must be greater than zero. So $\phi_{k,l}$, so $\phi_{l,k}$ when l is less than k is equal to $\phi_{k,l}$ inverse. So it is nothing but $\phi_{k,0}$ inverse. Now $\phi_{k,0}$ is what? $\phi_{k,0}$ is A_0, A_1, A_2, A_1, A_k whether A_k minus one inverse. So you see when when when you have k is equal to 2, then you have A_0, A_1 inverse, right.

So in this way it will go, next one will be one inverse, next one will be i . So these are you know, kind of inverse state transition matrices, if you know what are state transition matrices. This is this is just algebra. I mean mean I I mean I just wanted to show that, you it is it is it is indeed possible to be cast in that form. So the so the major thing is that, you can cast you can write this problem into this linear form; in which we have already solved this problem.

(Refer Slide Time: 14:45)

To find the estimate \hat{x}_k that considers $v_j; j=0, \dots, k$ © CET
I.I.T. KGP

Let $\bar{v}_j = \begin{bmatrix} v_{0,j} \\ \vdots \\ v_{j,j} \end{bmatrix} \quad j=0, 1, \dots$

Then we have the model

$$\bar{v}_j = H_{R,j} x_k + \bar{\epsilon}_{R,j}$$

$\bar{\epsilon}_{R,j} \leftarrow P_k$

$C_k \rightarrow H_{R,j} = \begin{bmatrix} C_0 \Phi_{0,k} \\ \vdots \\ C_0 \Phi_{j,k} \end{bmatrix} \quad \bar{\epsilon}_{R,j} = \begin{bmatrix} \epsilon_{R,0} \\ \vdots \\ \epsilon_{R,j} \end{bmatrix}$

where $\Phi_{l,k} = \begin{cases} A_{l-1} A_{l-2} \dots A_k & l > k \\ I & l = k \\ \Phi_{R,l}^{-1} & l < k \end{cases}$

$$\epsilon_{R,l} = \eta_l - C_l \sum_{i=l+1}^k \Phi_{l,i} \prod_{i-1}^k \xi_{i-1}$$

$$y_k = A_k x_k + \beta \beta_k$$

$$y_k = C_k x_k + \eta_k$$

But this will now if you if you now solve this least square problem, and then choose our weight according to the according to the; see previously what what happened? Here what did we have? Previous problem, we had here we had ξ_k , if you recall and this one was our C_k , correct. So now so now we have we we are trying to solve this this augmented problem. So so we will do exactly the same thing. That is after all the least square solution, I mean does not depend on the interpretation as long as you have a problem in this form; you will get the same least square solution, is it not? So therefore now we can use our last result, that is this is just what I proved, just right now, the same thing written in written in general notation.

(Refer slide Time: 15:40)

From transition property of Φ_{ki} and

$$x_k = \Phi_{kk} x_{k-1} + \sum_{i=k+1}^R \phi_{ki} \Gamma_{i-1} \xi_{i-1}$$

$$x_{k-1} = \Phi_{k,k-1} x_k - \sum_{i=k+1}^R \phi_{k,i-1} \Gamma_{i-1} \xi_{i-1}$$

Then

$$H_{kj} x_k + \bar{E}_{kj}$$

$$= \begin{bmatrix} c_0 & \phi_{0k} \\ \vdots & \vdots \\ c_j & \phi_{jk} \end{bmatrix} x_k + \begin{bmatrix} \eta_0 - c_0 \sum_{i=1}^R \phi_{0i} \Gamma_{i-1} \xi_{i-1} \\ \vdots \\ \eta_j - c_j \sum_{i=j+1}^R \phi_{ji} \Gamma_{i-1} \xi_{i-1} \end{bmatrix}$$

$$= \begin{bmatrix} c_0 x_0 + \eta_0 \\ \vdots \\ c_j x_j + \eta_j \end{bmatrix} = \begin{bmatrix} v_0 \\ \vdots \\ v_j \end{bmatrix} = \bar{v}_j$$

So x_k is equal to this, I did exactly that for for that for that one, two, case. So this we can skip, probably now.

(Refer Slide Time: 16:01)

By analogy optimal weight matrix

$$W_{k,j} = (\text{Var}(\bar{E}_{k,j}))^{-1}$$

$$\bar{E}_{k,k-1} = \begin{bmatrix} \eta_0 - c_0 \sum_{i=1}^R \phi_{0i} \Gamma_{i-1} \xi_{i-1} \\ \vdots \\ \eta_{k-1} - c_{k-1} \sum_{i=k}^R \phi_{k-1,i} \Gamma_{i-1} \xi_{i-1} \end{bmatrix}$$

$$\text{Var}(\bar{E}_{k,k-1}) = \text{Var}(A) + \text{Var}(B)$$

$$\text{Var}(A) = \begin{bmatrix} R_0 & & 0 \\ & \ddots & \\ 0 & & R_{k-1} \end{bmatrix}$$

$$W_{k,k}^{-1} = \begin{bmatrix} W_{k,k-1}^{-1} & 0 \\ 0 & R_{k,k} \end{bmatrix}$$

So now now we know, now previously what did we see? We see we saw that, if we choose $W_{k,j}$ equal to $R_{k,j}$ inverse, we get the optimal solution. What was $R_{k,j}$? $R_{k,j}$ was variance of these, in our last this problem. So now we have to choose variance of this as the optimal

weight matrix. So we have to choose $W_{k,j}$ as variance of this term, there is a lot of algebra here today; we cannot help, it is probably the simplest case, we cannot so so so please bear with me and try to understand. Now this term is of this form, as we have already seen that it will contain all these η , one η term and the rest will be all a linear combination of this past ξ terms, is what it will be.

So so so there are two terms, now the question is that; if this is ϵ , what is variance of ϵ ? So we want to find out this W , imagine that what are we trying to say? We are trying to say, that is a stochastic vector A and if there is another random vector B , what is the variance of A plus B ? That is what we are trying to find out. So now can you imagine, what we what we are trying to do? You have a vector and we are trying to, so you know one interesting thing about matrices; is that if you can if you if you break them into sub vectors, and if you can write it as a block matrix. For example this itself is a vector, but just for the time being treat it as an element. It is a vector but just treat it as a scalar element. So then this matrix has this element, this element this element, as if they are scalars then if you just multiply, then when the same same kind of results will follow.

So you do not really need to treat them as vector and get more complicated. So so if you have, what is variance of A plus B ? In this case it will be variance of A plus variance of B , why? Because these two vectors are independent, because here we have.. what were our assumptions? Our assumptions was that η and ξ are totally uncorrelated. So so any of these terms, that is this and this no correlation and so now what is what is variance of A again? We have assumed that, each one of them are actually white. So therefore η_0 is not correlated with η_1 , is not correlated with η_2 . So therefore when you take variance of A , you get individual variance of η_0 , individual variance of η_1 , their cross variations are zero, even η_0 , η_1 does not have any cross correlation. This is our assumption in fact to make them in this form; we have made those assumptions, otherwise I mean the algebra becomes too complicated to solve.

So variance of A comes in this block diagonal form, these are these are individually matrices; because these are individually vectors, you have to visualise this, okay. Now Kalman filter is actually a recursive algorithm. So we have see how we we are not solving, you know what is the problem of solving this problem? The problem of solving this problem is that, as k goes

increasing; this vector becomes longer and longer in length. So after sometime it will become so long that, you will not be able to compute the solution. So we are not going to compute the solution that way. So we have to have a finite fixed dimensional problem; whatever equations we have must have constant dimension vector, we cannot our problem in which the vector dimension is increasing with time. So therefore we have to **recursify** it, that is we have to compute our new solution; based on our earlier solution and some constant computation. Unless we bring any algorithm in that form, it is not useful to compute in, I mean especially in real time. So therefore our objective is that, we have to we have to **recursify** this form; we know the so we know the non-recursive solution, but it is not useful right. So we had that is what we are trying now.

Now let us see what happens? What is this remember what is this $W_{k,j}$? $W_{k,j}$ is the weight matrix, when you try to solve for x_k ; taking care of measurements from v_0 to v_j , that is why we called it $W_{k,j}$, correct. Because on the left hand side we have v_0 to v_j and we are trying to solve for x_k . Now let us see, now we are trying to we we will go about (**recursifying**) ((00:21:31 min)) it, so we will first note that first note this identity. This is pretty cool, because after all W^{-1} is this inverse; so therefore W^{-1} is nothing but the variance. So what is $W^{-1} k$? $W^{-1} k$ means, I am trying to solve for x_k taking measurements from v_0 to v_k same instant; and at every instant my measurement vector is increasing by one, correct, correct. Some v_0 to v_{k-1} , then I am adding one v_k term at the bottom it becomes a longer problem, okay.

So if I take the inverse of this it will become a longer matrix, I mean the variance of this; because with the error term also one more one more block rows will come. So when you take the variance of that; then you will get for the first n minus rows, for the first n minus one rows you will get the k k minus one problem. So k k minus one, k minus one means you are trying to take care of measurement from v_0 to v_{k-1} . So you have v_0 , v_1 , v_2 , v_{k-1} . Now on the left hand side you have added another row v_k . So when you take when you multiplied by its transpose, then you will get the block matrix and you will get one matrix corresponding to v_k , v_k transpose. That is the rather rather η_k , because a new row η_k will now appear here. So corresponding to that, you will have R_k , k .

So first thing is that this can be written like this, we have a long way to go out so do not shy okay. I have tried to make it simpler than the original source, from where is which it is taken now. Remember our old solution, what was our solution? What it what is our solution?

(Refer Slide Time: 23:35)

By analogy,

$$\hat{x}_{k,j} = (H_{k,j}^T W_{k,j} H_{k,j})^{-1} H_{k,j}^T W_{k,j} \bar{y}_j$$

Now,

$$H_{k,k}^T W_{k,k} H_{k,k} = \begin{bmatrix} H_{k,k-1}^T & C_k^T \end{bmatrix} \begin{bmatrix} W_{k,k-1} \\ R_k^{-1} \end{bmatrix} \begin{bmatrix} H_{k,k-1} \\ C_k \end{bmatrix}$$

$$= H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k$$

Similarly,

$$H_{k,k}^T W_{k,k} \bar{v}_k = H_{k,k-1}^T W_{k,k-1} \bar{v}_{k-1} + C_k^T R_k^{-1} v_k$$

Hence

$$\hat{x}_{k,k} = (H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k)^{-1} (H_{k,k-1}^T W_{k,k-1} \bar{v}_{k-1} + C_k^T R_k^{-1} v_k)$$

$$= H_{k,k-1}^T W_{k,k-1} \hat{x}_{k,k-1} + C_k^T R_k^{-1} v_k$$

and, $\hat{P}_{k,k} = H_{k,k-1}^T W_{k,k-1} \bar{P}_{k-1} + C_k^T R_k^{-1} v_k$

Our our solution, if you recall was finally after putting that R k inverse matrix. Our first problem taking only vk was C k transpose, R k inverse, C k whole inverse, C k transpose, R k into V k that was the solution. So the so I have just put the corresponding ones, this is corresponding to C k. This is corresponding to R k inverse, W k. So I have just put those. This is a this is C k transpose, R k inverse, C k whole inverse, C k transpose, R k, R k inverse v, v k; this was our solution. Just put them in the because, it because this is same problem longer dimension.

So this is my x hat k j, that is the optimal estimate of x k; taking into factor measurements from v zero to v j, this is my general solution. Now I have to **recursify** it, which means that I have to go from k minus one to k. Then again from k to k plus one then like this I have to go, right. So essentially I have to put as j, I have to put k minus one and k and see how are how they relate? So that is very simple. Now from from the previous from the previous two formulae that we have already obtained,

(Refer Slide Time: 24:52)

$$W_{k,j} = (\text{Var}(\hat{E}_{k,j}))^{-1}$$

$$\hat{E}_{k,k-1} = \begin{bmatrix} \eta_0 - c_0 \sum_{i=1}^k \phi_{0,i} \Gamma_{i-1} \xi_{i-1} \\ \vdots \\ \eta_{k-1} - c_{k-1} \sum_{i=k}^k \phi_{k-1,i} \Gamma_{i-1} \xi_{i-1} \end{bmatrix}$$

$$\text{Var}(\hat{E}_{k,k-1}) = \text{Var}(A) + \text{Var}(B)$$

$$\text{Var}(A) = \begin{bmatrix} R_0 & 0 \\ 0 & \ddots \\ 0 & R_{k-1} \end{bmatrix}$$

$$W_{k,k}^{-1} = \begin{bmatrix} W_{k,k-1} & 0 \\ 0 & R_{k,k} \end{bmatrix}$$

$$= H_{k,k-1}^T W_{k,k-1} \hat{V}_{k-1} + C_k^T R_k^{-1} C_k \hat{Z}_{k,k-1}$$
 and,
$$\hat{Z}_{k,k} = H_{k,k}^T W_k \hat{V}_R = H_{k,k-1}^T W_{k,k-1} \hat{V}_{k-1} + C_k^T R_k^{-1} \hat{V}_R$$

that is this one equal to this and H k, k is nothing but H k look at H k, k

(Refer Slide Time: 25:00)

To find the estimate x_k
 Let $\bar{v}_j = \begin{bmatrix} \bar{v}_{j,0} \\ \vdots \\ \bar{v}_{j,j} \end{bmatrix} \quad j = 0, 1, \dots$
 Then we have the model $\bar{v}_j = H_{k,j} x_k + \bar{e}_{k,j}$

$$H_{k,j} = \begin{bmatrix} c_0 \phi_{0,k} \\ \vdots \\ c_0 \phi_{j,k} \end{bmatrix} \quad \bar{e}_{k,j} = \begin{bmatrix} \bar{e}_{k,0} \\ \vdots \\ \bar{e}_{k,j} \end{bmatrix}$$

 where $\phi_{l,k} = \begin{cases} A_{l-1} A_{l-2} \dots A_k & l > k \\ I & l = k \\ I_{l-k} & l < k \end{cases}$

$$\eta_l = \eta_l - c_l \sum_{i=l+1}^k \phi_{l,i} \Gamma_{i-1} \xi_{i-1}$$

what is H k, k? H k, k will be C0 phi0 k, C0 phi j k. So if you have H k, k you will have how many zero k? one k, two k, three k, up to j k. So in in this case, it will be k k, if you have k k minus one; you will have one row less, correct. So so therefore; you can always partition the matrix like this and and what is phi k, k? Rather phi k, k is one because from from to to

take the state estimate from k minus one to k; you need to multiply it by the matrix A, but is it not what were we doing. We were, see, we have we were multiplying

(Refer Slide Time: 25:52)

$$y_0 = C_0 \underline{x_0} + \eta_0$$

$$x_1 = A_0 x_0 + \Gamma_0 \xi_0$$

$$x_2 = A_1 [A_0 x_0 + \Gamma_0 \xi_0] + \Gamma_1 \xi_1$$

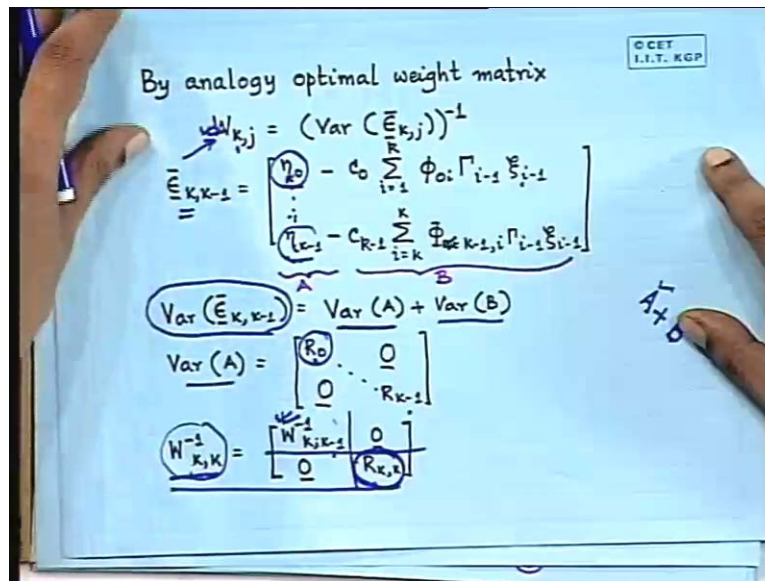

$$x_2 - A_1 \Gamma_0 \xi_0 - \Gamma_1 \xi_1 = \underline{A_1 A_0} x_0$$

$$x_0 = [A_1 A_0]^{-1} x_2 - A_1 A_0^{-1} [A_1 \Gamma_0 \xi_0 - \Gamma_1 \xi_1]$$

$$\begin{bmatrix} y_0 \\ y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} C_0 [A_1 A_0]^{-1} x_2 - C_0 A_0 \Gamma_0 \xi_0 - C_0 (A_1 A_0)^{-1} \Gamma_1 \xi_1 + \eta_0 \\ C_0 A_1^{-1} x_2 - C_0 A_1^{-1} \Gamma_1 \xi_1 + \eta_1 \\ C_0 x_2 + \eta_2 \end{bmatrix}$$

See if you want, if you want to take x_0 to x_1 , you have to multiply by A_0 . If we have to take x_k to x_k you have to multiply by the identity matrix. So ϕ_k, k it is the it is the state transition matrix, I think so between k and k the matrix is I . So therefore, so therefore here you have only C_k , no ϕ because ϕ_k, k is one. So you can partition the matrix like this; H_k k is this one plus one addition row, in this case one additional column because this transposed actually it is like this C an additional row. And W_k, k we have we we have already partitioned, that will come like this; because if if this is W inverse k, k then then W_k, k will be just again just treat them like a diagonal matrix as if these are scalar elements.

(Refer Slide Time: 26:40)

So it will be the inverse of this and the inverse of this, if you see these are the terms that I mean usefulness of block matrices. So then W_k , k is this inverse. Now you multiply this and you get, simply just multiply a diagonal matrix. So you get this term, so this term see why I have tried to relate them? What is if that I have got, if I put x_k , k I will get all these terms. That is if I put j is equal to k , I will get this term here. Now I have to relate it with j equal to k minus one. So if I put j equal to k minus one, I will get this term here.

So I have to be able to relate them, that is why I am trying to relate them; that is how this matrix relates to this solution. So I have related and then found that, that this is the relationship and this term appears additional. I must go from k minus one to k gradually; as I get new measurements as I want to go in advance, that is from x_k to x_{k-1} . So all those I have to do, okay. And so this part I have taken care of, now I have to take care of this part. So this part now I am writing; exactly in the similar way that this part will be like this, again simply by partitioning multiply only this to this. So you get this into plus this into this, that into v_{k-1} . And the total thing is in place of this vector, put this vector. This vector is V_{k-1} on top and small v_k at the bottom; so multiply these three you will get this, so now this part I have related here and this part I have related here, okay.

Systematically, only this that they are a few matrices; we have to carefully keep indexes, maintain, you have to go and multiply. So now if you find, now now you put it here, that is this whole... So now how do you get this? If you put k , k minus one, put j is equal

to k minus one, j is equal to k minus one, j is equal to k minus one and then on the left hand side; if you.. say this is assumption number two, what was assumption number one? That all the A 's are invertible, that was assumption number one. Now here is assumption number two that this is invertible. Previously also in in our last problem also; we we assume that that C_k transpose, R_k inverse, C_k is invertible same assumption we made. See if this invertible, you can pre-multiply this by this. So then this thing, you have this thing you are pre-multiplying with this and you are adding this term. Now this into this from this equation; so pre-multiply this for j is equal to k minus 1. This will come here j is equal to k minus 1 will be equal to this.

So this into this is this term, and and and this is simply added, correct. Now this whole thing is, what? This one, so this A this total term I have called A ; so this term is A and wait wait wait, correct. Now this is if you put j is equal to k , then this term becomes what? k k k k k everything will become k , all the j 's will become k . If you want to solve for x hat k , k if you want to solve for x hat k , k minus 1 in place of j ; everywhere you have to put k minus, this is general equation. So similarly you can write that, just like you have written this one; that is this inverse, this is equal to this. So you can write that same equation, either for j equal to k minus one or for j equal to k . If you write it for j is equal to k , then you wil get this inverse, this into this is equal to this for for j is equal to k .

Now now this, so exactly that is what I have written. Now this equal to A ; see this one from this equation, this is A the same A is here. This whole term is A , so what you are doing is so you have and so A is equal to this. So A into x_k , k is obviously this one; that is same equation I have put j is equal to k , this is the same equation I have put j equal to k . And that is equal to that is equal to what? That is equal to, this one I have broken up, no no no I am getting, I I

Student <first term on the right hand side k , k value>

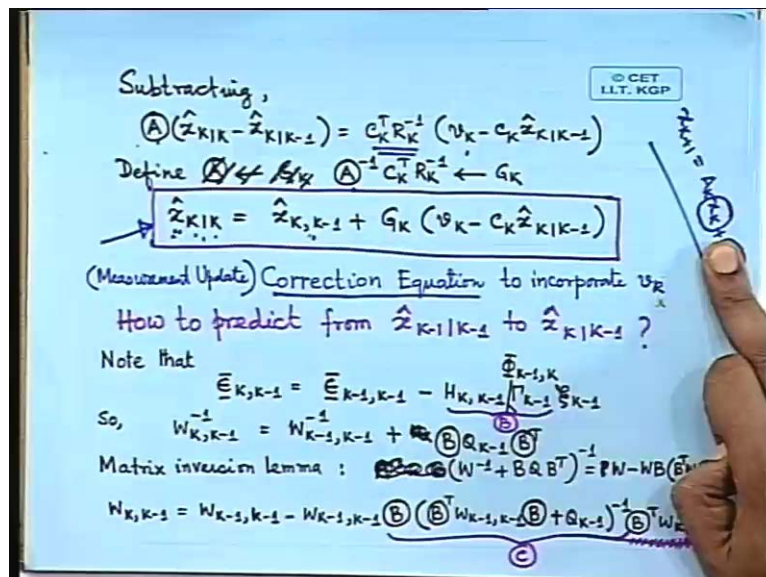

[Conversation between Student and Professor – Not audible ((00:32:50 min))]

This one, this one, it is this one. See the I got this one and this one I have already said that, that this one equal to this one. So I have just put it here, now I am going to subtract. Here I have got A into x_k k , given k minus 1, here I have got A into x_k given k ; have to finally

express x_k given k in terms of x_{k-1} given $k-1$, what am I getting? This is called the measurement update. That is I am estimating x_k based on measurement from $v_0, v_1, v_2, \dots, v_{k-1}$. That is my estimate $\hat{x}_{k|k-1}$ given $k-1$, given means given measurements up to. Now I get another measurement which is v_k ; so I have some more information, so ideally speaking I should be able to estimate x_k even better. So how do I now update my previous estimate $\hat{x}_{k|k-1}$, after I get a new measurement and make it $\hat{x}_{k|k}$, this is what I am trying to do.

So I am trying to generate $\hat{x}_{k|k}$ from $\hat{x}_{k|k-1}$, after another set of measurement of V_k becomes available to me. That is what I am trying to get at, okay; because as I get more and more measurements, I should be able to refine my estimate more and more. So I am that, that is why so now so exactly, so now you subtract this and this; that is subtract this from this simply subtract, which terms will get cancelled? These two terms will get cancelled, so you will have this A that is that old term into this is equal to so so so these two terms; as I said will get cancelled, this one will cancelled with this one.

(Refer Slide Time: 34:57)

(Refer Slide Time: 35:04)

By analogy,

$$\hat{x}_{k|j} = (H_{k,j}^T W_{k,j} H_{k,j})^{-1} H_{k,j}^T W_{k,j} \bar{z}_j$$

Now,

$$\rightarrow H_{k,k}^T W_{k,k} H_{k,k} = \begin{bmatrix} H_{k,k-1}^T & C_k^T \end{bmatrix} \begin{bmatrix} W_{k,k-1} \\ R_k^{-1} \end{bmatrix} \begin{bmatrix} H_{k,k-1} \\ C_k \end{bmatrix}$$

$$= H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k$$

Similarly,

$$\rightarrow H_{k,k}^T W_{k,k} \bar{v}_R = H_{k,k-1}^T W_{k,k-1} \bar{v}_{k-1} + C_k^T R_k^{-1} v_k$$

Hence

$$\begin{aligned} & (H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k) \hat{x}_{k|k-1} \\ &= H_{k,k-1}^T W_{k,k-1} H_{k,k-1} \hat{x}_{k|k-1} + C_k^T R_k^{-1} C_k \hat{x}_{k|k-1} \\ \text{and, } & \hat{x}_{k|k} = H_{k,k}^T W_{k,k} \bar{v}_R = H_{k,k-1}^T W_{k,k-1} \bar{v}_{k-1} + C_k^T R_k^{-1} v_k \end{aligned}$$

So they are same only these two will remain. So you get this and then then from this you can just invert the other one; so you can write $\hat{x}_{k|k}$ is $\hat{x}_{k|k-1}$ plus all these. That is this inverse this, you have to we are basically multiplying by this inverse on on both side pre-multiplying; so then this will go off. This will this inverse, A inverse will come here this one, and then take $\hat{x}_{k|k-1}$ on the other side; this is the first equation on the Kalman filter, which says that if you had a measurement, if you had an estimate of x_k given measurements up to $k-1$ and if you get a new measurement v_k , now. Then this is the way that, you must update your your your estimate; to make it now optimal with respect to the with respect to the set of measurements, from v_0 to v_k .

So basically what I have done? I have solved one block problem, I have shown that if you solve this this least square problem based on this block thing; first you solve it for $k-1$ then you include the new measurement, it becomes a longer vectors, longer matrices then you solve it for k . If you get this two solutions of the same thing x_k , then these solutions are actually related like this. This is what I have proved by lot of jugglery with matrices, nothing else. It is just algebra plains taking, tedious, but simple algebra there is no big concept in it.

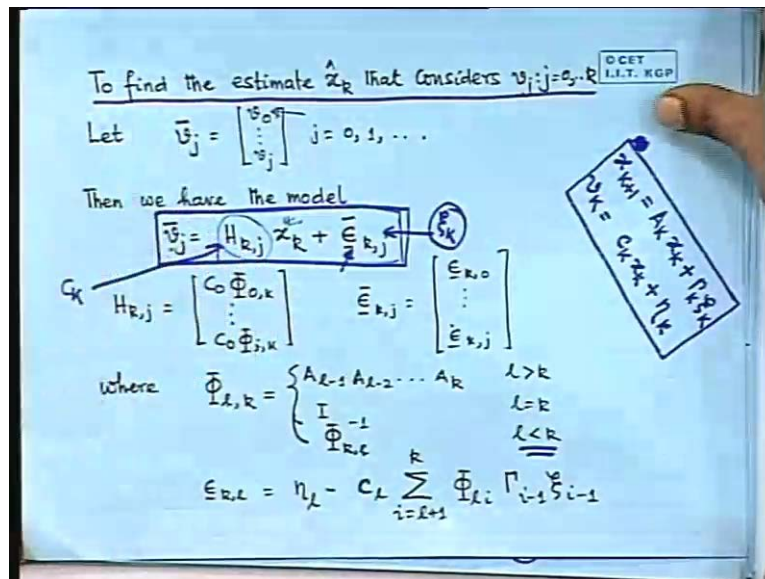

This is sometimes called the correction equation, because actually the Kalman filter is supposed to be divided into two parts; one kind one part is called the prediction equation

where you go from x_k to x_{k+1} that is you that the estimate, at which instant is the estimate that you advance. Another is you you relate two estimates at the same time step but which take measurements, which which taking a new measurement into account. So one is a measurement update which is called a correction equation; in the in the sense that you first obtain an estimate of x_k , without any measurement at the instant k . So only up to $k-1$ then once you got that, then you you you you correct your estimate, once you get a measurement at k . So that is why it is sometimes called the correction equation and sometimes called a measurement update, because this equation is executed once you get the measurement at k . So it is a measurement update.

So I have related this to this, but remember that we have still; that is my estimate is at the same instant k , but if I have to go on doing it then I have to advance k . I have to first make a make a make an estimate of x_1 , then I make to then then I make an estimate of x_2 , then make an estimate x_3 , so have to advance the first index. So how do I advance the first index? I have to advance time, okay. Here I did not advance time, I am.. left hand, right hand side I am I am standing at k . So advancing time is is again simple; involves matrices there is one see interestingly, I mean there are there are there are two approaches one one thing is going again rigorously, see we have I mean one one good thing is that we have solved the problem for for arbitrary k and j , on the two sides of this this problem this this this basic problem that we have formulated.

Fortunately k and j are actually unrelated in the sense that, j can be anything between zero to k . So so that way, I can I can write this problem for some value of k and some value of j .

(Refer Slide Time: 39:33)

So exactly one way is to again write these two problems; for now k is equal to k minus one on one side and k is equal to k on the other side, and then try to relate them that is the rigorous approach then written here. But then before we come to that, let us get a sort of you know, what is called as sneak preview kind of staff; that is just imagine you are I mean you are you have some state, right. So you have how is x_k plus one and x_k related? $A_k x_k$ plus $\gamma \xi_k$, this is how it is related, correct. Now you have already made an estimate of this; that was your \hat{x}_k given k that is the best estimate possible, because you have taken measurements up from zero to k into account. You cannot get future measurements, okay. So you have done all that you could in this.

Now standing there without any measurement, you want to look forward, correct. So how do you look forward? Obviously how does a system look forward? How does the true state get advanced in time? By like this, correct. Now so obviously you will have to use this rule, but then what about this? The question is that, here is something it is had it been simply this $A_k x_k$, you would have said that my estimate is x_k plus one equal to $A_k \hat{x}_k$ given k . If it was simply this then you would have also applied the same rule; because there is a there is nothing else; now the only problem is that you have something else, you have this one.

So the question is that, can you estimate even a part of this? That is the question but you cannot, why you cannot? Because this x_i in this estimate, you have taken care of all process noise up to k minus one and you have already made an assumption; that the process noise is uncorrelated, in the sense that x_i k the you cannot get any information about x_i k from all from zero to k minus one, that is the that is the nature of the random process.

So so from your previous measurements of x_i zero to x_i k minus one, you cannot get any information about x_i . So if you do not have any information about x_i k ; what is what is the best strategy? Best strategy is to assume that it is in the mean value, because it is completely random. What is the mean value? Zero. So so still even if this is there under the assumption of that stochastic characterisation, it is still best to just propagate with through A , this is an this is an intuitive picture. Now now the same intuitive is actually you can you you can rigorously compute, again the those two solutions for k minus one and k and then and then arrive at the same.

I.I.T. KGP

Since, $H_{k,k-1} = H_{k-1,k-1} \Phi_{k-1,k}$

$$H_{k,k-1}^T W_{k,k-1} = \Phi_{k-1,k}^T \left\{ I - H_{k-1,k-1}^T W_{k-1,k-1} \right\} \Gamma_{k-1}^T \Phi_{k-1,k}^T W_{k-1,k-1}^{-1}$$

(D)
$$\left(H_{k,k-1}^T W_{k,k-1} H_{k,k-1} \right) \Phi_{k-1,k}^{-1} \left(H_{k-1,k-1}^T W_{k-1,k-1} H_{k-1,k-1} \right)^{-1}$$

$$= \Phi_{k-1,k}^T \left\{ I - H_{k-1,k-1}^T W_{k-1,k-1} \Gamma_{k-1}^T \Phi_{k-1,k}^T \right\}^{-1}$$

(E)
$$H_{k,k-1}^T W_{k,k-1} = H_{k-1,k-1}^T W_{k-1,k-1} - H_{k-1,k-1}^T W_{k-1,k-1} \Gamma_{k-1}^T H_{k-1,k-1} W_{k-1,k-1}^{-1}$$

$$= H_{k-1,k-1}^T W_{k-1,k-1}$$

(E)
$$\bar{v}_{k-1} = H_{k-1,k-1}^T W_{k-1,k-1} \bar{v}_{k-1}$$

$$\Rightarrow A_{k-1} \left[\left(H_{k-1,k-1}^T W_{k-1,k-1} H_{k-1,k-1} \right)^{-1} H_{k-1,k-1}^T W_{k-1,k-1} \bar{v}_{k-1} \right]$$

$$= \left(H_{k-1,k-1}^T W_{k-1,k-1} H_{k-1,k-1} \right)^{-1} H_{k-1,k-1}^T W_{k-1,k-1} \bar{v}_{k-1}$$

$$\Rightarrow \hat{x}_{k|k-1} = A_{k-1} \hat{x}_{k-1|k-1} \leftarrow \text{Prediction Eqn (Time Update)}$$

See all these because of the fact that, that you have to you what is involved is what is what is known as, the matrix inversion lemma which of you might have studied in some other courses A plus, B , C , D inverse is equal to there is there is there is a big formula. A inverse minus A inverse B transpose... I mean I do not recall what the formula is, I always look it up.

So you can again go through that same thing and go on substituting all that, but finally you will get this.

(Refer Slide Time: 43:17)

$$\begin{aligned}
 & (H_{k,k-1}^T W_{k,k-1} H_{k,k-1}) \Phi_{k,k-1} (H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} \\
 & = \Phi_{k,k-1}^T \left\{ I - H_{k,k-1}^T W_{k,k-1} (H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} H_{k,k-1} \right\} \\
 & \text{D } H_{k,k-1}^T W_{k,k-1} = H_{k,k-1}^T W_{k,k-1} - H_{k,k-1}^T W_{k,k-1} (H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} H_{k,k-1} \\
 & \text{E } \bar{y}_{k-1} = H_{k,k-1}^T W_{k,k-1} \bar{y}_{k-1} \\
 & \Rightarrow A_{k-1} \left[(H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} H_{k,k-1}^T W_{k,k-1} \bar{y}_{k-1} \right] \\
 & = (H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} H_{k,k-1}^T W_{k,k-1} \bar{y}_{k-1} \\
 & \Rightarrow \hat{x}_{k|k-1} = A_{k-1} \hat{x}_{k-1|k-1} \quad \leftarrow \text{Prediction Eqn (Time Update)} \\
 & = \left\{ I - P_{k,k-1} C_k^T (C_k P_{k-1} C_k^T + R_k)^{-1} C_k \right\} P_{k,k-1}
 \end{aligned}$$

What we intuitively argued; that if you want to take, here is an estimate of \hat{x}_{k-1} , which you have generated using measurements up to $k-1$. Now you want to propagate the state up to k without having any additional measurement. So if you want to do that, you multiply simply by A_{k-1} . There is no better that, you can do simply because you cannot get any other information about the process noise from the past, that you have seen. So all these mathematics, all these equations we will finally give you the next equation of the Kalman filter; which is called a prediction equation or sometimes called a time update, because here you are advancing time and in other words without any measurement beyond $k-1$, you are trying to predict the state at k . Therefore it is called a prediction equation.

So either you have a predictor equip, predictor corrector formulation, there are various terms which are mentioned in the context of the Kalman filter; but these two are the basic state update equations. Now but the Kalman filter has many other equations, why? It has at least three four other equations, that is because of these, actually these two are the status.. basic state estimation, equation are these two; this prediction equation and this corrector equation. But now people will people wanted to say that this G_k , this G_k also should be you

know efficiently computed again recursively; that is every time I do not want to solve, you see what is G_k ? G_k is this A inverse, this now what does A involve? A involves big big quantities.

(Refer Slide Time: 45:15)

By analogy,

$$\hat{x}_{k|j} = (H_{k,j}^T W_{k,j} H_{k,j})^{-1} H_{k,j}^T W_{k,j} \bar{y}_j$$

Now,

$$\begin{aligned} \rightarrow H_{k,k}^T W_{k,k} H_{k,k} &= [H_{k,k-1}^T \quad C_k^T] \begin{bmatrix} W_{k,k-1} \\ R_k^{-1} \end{bmatrix} \begin{bmatrix} H_{k,k-1} \\ C_k \end{bmatrix} \\ &= H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k \end{aligned}$$

Similarly,

$$\rightarrow H_{k,k}^T W_{k,k} \bar{y}_k = H_{k,k-1}^T W_{k,k-1} \bar{y}_{k-1} + C_k^T R_k^{-1} y_k$$

Hence

$$\begin{aligned} & (H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k) \hat{x}_{k|k-1} \\ &= H_{k,k-1}^T W_{k,k-1} H_{k,k-1} \hat{x}_{k|k-1} + C_k^T R_k^{-1} C_k \hat{x}_{k|k-1} \\ \text{and, } \hat{x}_{k|k} &= H_{k,k-1}^T W_{k,k-1} \bar{y}_{k-1} + C_k^T R_k^{-1} y_k \end{aligned}$$

A involves A , what is A ? This one, now you see these again increase in length as k increases. H increases in length, W increases in length; so you cannot compute A inverse using this equation. So therefore again you have to bring that into some constant, constant computation time kind of form, right. So the rest of the equations are rest of the equations of the Kalman filter are devoted just to make this computation of G_k a constant computation which you does not increase with time, because otherwise you cannot use it.

So five minutes, so the question is how to update G_k recursively?

(Refer Slide Time: 46:03)

How to update G_k recursively? © CET
I.I.T. KGP

$$G_k = (H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k)^{-1} C_k^T R_k^{-1}$$

$$= \boxed{(H_{k,k}^T W_{k,k} H_{k,k})^{-1}} C_k^T R_k^{-1}$$

$$= \underbrace{P_{k,k}}_{\text{PKK}} C_k^T R_k^{-1}$$

$$P_{k,k}^{-1} = P_{k,k-1}^{-1} + C_k^T R_k^{-1} C_k$$

By M.I. Lemma

$$P_{k,k} = P_{k,k-1} - P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1}$$
~~$$P_{k,k}^{-1} = P_{k,k-1}^{-1} + C_k^T R_k^{-1} C_k$$~~

$$= \left\{ I - P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k \right\} P_{k,k-1}^{-1}$$

It is given G_{k-1} , how to get G_k from there using a constant computation at all k . So now again again a matrix algebra. Now this is this is just I have restated that formula; A inverse this again written it for your reference, this is nothing but this, let us give it a term called, P_k . This is sometimes called the process noise covariance, no not process noise covariance, state estimate covariance, state error covariance, why that we will see. But let us give it a name, we have given the name P_k ; because here also k , here also k so we have given P_k . So one thing is clear that, this is and correct. Obviously; if if this is P_k , this inverse remember that, P_k is the whole thing including the inverse. So then P_k inverse is the inner thing, just this one.

So obviously P_k inverse equal to from this equation itself, P_k inverse equal to this equation; this this is this follows from here to here. Now there is a matrix inversion lemma, again matrix inversion lemma is arrive in different forms. You know so again matrix, you know this is nothing this the it is a kind of matrix identity; people have said that, A plus B , C , D inverse if you do, it equates to that. It it is the identity, it will hold for all matrices which compute; so no problem it is just happens. It just a you know a cute observation, which somebody made regarding matrices.

So so lot of manipulation, putting this here, that here, taking left pre-multiplication ((00:48:05 min)) common and all that; You can you can read it, you can try this, this is not, mean I mean cannot really I mean you know recite these equations here. So finally it turns out that, m you can cast it in the in these two equations; this just nothing but manipulation, if you see in the notes, in fact I have tried to make it more simplified than the source.

(Refer Slide Time: 48:19)

Handwritten mathematical derivations on a blue background:

$$G_k = (P_{k,k-1}^{-1} + C_k^T R_k^{-1} C_k)^{-1} C_k^T R_k^{-1}$$

$$= [P_{k,k-1} - P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1}] C_k^T R_k^{-1}$$

$$= P_{k,k-1} C_k^T [I - (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1} C_k^T] R_k^{-1}$$

→ $G_k = P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1}$ (with $R = R_k$ indicated)

Thus → $P_{k,k} = (I - G_k C_k) P_{k,k-1}$

What are $P_{k,k-1}$ and $P_{k,k}$?

$$\hat{z}_{k,k-1} = (H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} H_{k,k-1}^T W_{k,k-1} \bar{z}_{k-1}$$

$$= \bar{z}_{k-1} + P_{k,k-1} H_{k,k-1}^T W_{k,k-1} \bar{e}_{k,k-1}$$

$$\text{Var}(\bar{z}_{k-1} - \hat{z}_{k,k-1}) = P_{k,k-1} (H_{k,k-1}^T W_{k,k-1} \text{Var}(\bar{e}_{k,k-1}) W_{k,k-1} H_{k,k-1} + P_{k,k-1})^{-1} P_{k,k-1}$$

$$= P_{k,k-1}$$

(Note: $\text{Var}(\bar{e}_{k,k-1}) = I$ is indicated in the original image)

I mean the the source from which this is adopted, that is chuan chens book; it none of these steps are are actually elaborated, where it will say, it can be shown, it it can be shown, it can be shown, but I have shown for your benefit, spending some midnight twelve.

So so finally you get this. This is nice see these are all these are all constant dimension matrices. So at least there is an inverse here which is slightly nagging but but this there is there is nothing whose dimension increases. So you have all constant matrices at at each instant k, same computation. Now there is a as I said that, this Pk's are called state error covariance's, why?

(Refer Slide Time: 49:20)

How to update G_k recursively? © CET
I.I.T. KGP

$$G_k = (H_{k,k-1}^T W_{k,k-1} H_{k,k-1} + C_k^T R_k^{-1} C_k)^{-1} C_k^T R_k^{-1}$$

$$= \boxed{(H_{k,k}^T W_{k,k} H_{k,k})^{-1}} C_k^T R_k^{-1}$$

$$= \underbrace{P_{k,k}}_{\text{PKK}} C_k^T R_k^{-1}$$

$$P_{k,k}^{-1} = P_{k,k-1}^{-1} + C_k^T R_k^{-1} C_k$$

By M.I. Lemma

$$P_{k,k} = P_{k,k-1} - P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1}$$
~~$$P_{k,k}^{-1} = P_{k,k-1}^{-1} + C_k^T R_k^{-1} C_k - P_{k,k-1}^{-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1}^{-1}$$~~

$$= \left\{ I - P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k \right\} P_{k,k-1}$$

I mean I just took some arbitrary form, I mean I just puts took some arbitrary formula matrices and then named it, P_k . So so how I can tell that it is a it is a state error covariance, that has to be proved.

(Refer Slide Time: 49:35)

© CET
I.I.T. KGP

$$G_k = (P_{k,k-1}^{-1} + C_k^T R_k^{-1} C_k)^{-1} C_k^T R_k^{-1}$$

$$= \left[P_{k,k-1} - P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1} \right]^{-1} C_k^T R_k^{-1}$$

$$= P_{k,k-1} C_k^T \left[I - (C_k P_{k,k-1} C_k^T + R_k)^{-1} C_k P_{k,k-1} C_k^T \right]^{-1} R_k^{-1}$$

$$\rightarrow G_k = P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} \quad \leftarrow R_k$$

Thus $\rightarrow P_{k,k} = (I - G_k C_k) P_{k,k-1}$

What are $P_{k,k-1}$ and $P_{k,k}$?

$$\hat{x}_{k,k-1} = (H_{k,k-1}^T W_{k,k-1} H_{k,k-1})^{-1} H_{k,k-1}^T W_{k,k-1} \bar{u}_{k-1}$$

$$= \hat{x}_k + P_{k,k-1} H_{k,k-1}^T W_{k,k-1} \bar{e}_{k-1}$$

$$\text{Var}(\hat{x}_k - \hat{x}_{k,k-1}) = P_{k,k-1} \left(H_{k,k-1}^T W_{k,k-1} \text{Var}(\bar{e}_{k-1}) W_{k,k-1} H_{k,k-1} \right) P_{k,k-1}^{-1}$$

$$= P_{k,k-1} W_{k,k-1}^{-1} P_{k,k-1}^{-1}$$

So you can actually prove you can actually prove that, this proof is also given here; that variance of x_k minus \hat{x}_k given k minus 1, evaluates to P_k , P_k k minus 1.

So what is this? This is state error. If you make an estimate of x_k taking measurements up to k minus one and then take the error from the true state; then and if you take its variance, then it will try to it will become P_k given k minus one. So therefore this is the covariance matrix of state error; that is why it is called state error covariance. Similarly by exactly same matrix algebra, you can you can compute even k given k , and you will get P_k k , same thing right.

(Refer Slide Time: 50:30)

Similarly,

$$E[(x_k - \hat{z}_{k|k})(x_k - \hat{z}_{k|k})^T] = \text{Var}(x_k - \hat{z}_{k|k}) = P_{k|k}$$

Now

$$\hat{z}_{k|k-1} = A_{k-1} \hat{z}_{k-1|k-1}$$

$$x_k = A_{k-1} x_{k-1} + \Gamma_{k-1} \xi_{k-1}$$

$$\Rightarrow (x_k - \hat{z}_{k|k-1}) = A_{k-1} (x_{k-1} - \hat{z}_{k-1|k-1}) + \Gamma_{k-1} \xi_{k-1}$$

Thus

$$P_{k|k-1} = A_{k-1} P_{k-1,k-1} A_{k-1}^T + \Gamma_{k-1} Q_{k-1} \Gamma_{k-1}^T$$

How to initialise?

$$\hat{z}_{0|0} = E(x_0)$$

$$P_{0,0} = E[(x_0 - E(x_0))(x_0 - E(x_0))^T] = \text{Var}(x_0)$$

So final thing, one there is there is only one thing remaining, so you see now what what have you what have you done in this equations? In this equation, you have calculated from P_k , k minus 1 to P_k , k . See using P_k , k minus 1 you can calculate G_k , using G_k and P_k , k minus 1 you have calculated P_k , k . So from k , k minus one you have gone to k , k ; so again it is like a measurement update, even for this you have to make a time update because everything must proceed in lock step.

So you have to now, final equation is that you have to take k k minus 1, you have to get from k minus 1, k minus 1, you have to update this one. So that is very simple, that is that is because simplify observing this equations. So this two are standard equations; so you now compute x_k , k minus 1, this side you get k minus 1, k minus 1. Now if you have a if if you have a vector which is like you know Ax plus B , then the vary say say y is equal to Ax plus B ; y is a vector, A is a matrix, x is a vector, v is a v is a vector. If you have such a case then

obviously variance of y will be A, variance of x A transpose; this is the this simple. So so just from this equation, you can get this equation because the variance of this is this and the variance of this is this, is very simple. How do you initialise this algorithm? You have to start with something because you are, every time you have to give some basic estimate of x hat zero, given zero and P zero given zero then you can take it up from k to k minus one.

So that is here is this this is your initial guess of x hat, you you know nothing about it. You have you have no measurement so far; so therefore you.. you you have what whatever is your mean estimate of your initial state, that you must put. And then P zero, zero will become the variance of so; that is why I said that you need to make assumptions about, the initial state as a random variable. You you need to make an assumption about its mean, and its variance. So that is how you initialize the algorithm, right. So finally we have made it in time, just in time by skipping some steps these are the Kalman filter equations.

The Kalman Filter Equations

© CET
I.I.T. KGP

$$\left. \begin{aligned} \hat{x}_{0|0} &= E(x_0) \\ P_{0|0} &= \text{Var}(x_0) \end{aligned} \right\} \begin{array}{l} \text{Initialization} \\ \text{Initialisation} \end{array}$$

$$\begin{array}{l} \text{Prediction} \\ \text{Time Update} \end{array} \left\{ \begin{aligned} \hat{x}_{k|k-1} &= A_{k-1} \hat{x}_{k-1|k-1} \\ \hat{P}_{k,k-1} &= A_{k-1} P_{k-1,k-1} A_{k-1}^T + \Gamma_{k-1} Q_{k-1} \Gamma_{k-1}^T \end{aligned} \right.$$

$$\begin{array}{l} \text{Kalman Gain Calculation} \\ \text{Correction} \\ \text{Measurement Update} \end{array} \left\{ \begin{aligned} G_k &= P_{k,k-1} C_k^T (C_k P_{k,k-1} C_k^T + R_k)^{-1} \\ \hat{x}_{k|k} &= \hat{x}_{k|k-1} + G_k (y_k - C_k \hat{x}_{k|k-1}) \\ P_{k,k} &= (I - G_k C_k) P_{k,k-1} \end{aligned} \right.$$

So you first initialise then after initialisation, what you do? Now you have no measurement, so from there you predict to x one. So from k minus 1 you predict to k so. First you apply the prediction equations, because you have no measurements so far. And similarly you update k to k minus 1 here. So these are your, so these are your time update equations, then you get your first measurement.

When you get your first measure; in the mean time you calculate G_k then after you get your first measurement, you correct this. And then again predict for the second measurement and then get, then again predict for the second time step and then get the second measurement correct it; then then again predict for the third time step. This is the way you go on and you get amazing results as we will see in the next class, thank you very much.
