Lecture – 12
Fourier series – Part 1

(Refer Slide Time: 00:16)

Average DC voltage,

$$V_d = \frac{1}{\pi/3} \int_{\alpha}^{\alpha+60} v_d d(\omega t) = \frac{3}{\pi} \int_{\alpha}^{\alpha+60} (e_b - e_c) d(\omega t) = \frac{3}{\pi} \int_{\alpha}^{\alpha+60} \sqrt{2} V \sin(\omega t + 60^\circ) d(\omega t) = \frac{3\sqrt{2}}{\pi} V \cos \alpha$$

V_{d0} ← Maximum average DC voltage
 $V_d = \frac{3\sqrt{2}}{\pi} V$
 $V_d = V_{d0} \cos \alpha$

Average power = $V_d I_d$
 If $0 \leq \alpha < 90^\circ$, $V_d > 0$, average power > 0
 Then converter operates as a rectifier

V_d $I_d > 0$
 (constant)

NPTEL

So, let me spend some time on the results of Fourier series.

(Refer Slide Time: 00:18)

Fourier Series of a periodic function $f(\omega t)$, with period 2π , is

$$\frac{a_0}{2} + \sum_{h=1}^{\infty} [a_h \cos(h\omega t) + b_h \sin(h\omega t)]$$

$$a_h = \frac{1}{\pi} \int_c^{c+2\pi} f(\omega t) \cos(h\omega t) d(\omega t), h=0, 1, 2, \dots$$

$$b_h = \frac{1}{\pi} \int_c^{c+2\pi} f(\omega t) \sin(h\omega t) d(\omega t), h=1, 2, 3, \dots$$

$\frac{a_0}{2}$ is average value of $f(\omega t)$

RMS value of fundamental component of $f(\omega t) = \sqrt{\frac{a_1^2 + b_1^2}{2}}$

RMS value of h^{th} order harmonic component of $f(\omega t) = \sqrt{\frac{a_h^2 + b_h^2}{2}}, h > 1$

Now, the intention is to get the magnitude of the harmonic components in the voltage on the DC site and also the magnitude of the harmonic components in the current on the AC site ok. So, some results may be useful in trying to compute the harmonic components. So, what we try to do here is consider a periodic waveform; please note whether its AC site or the current or the DC site voltage, they are periodic waveforms. Now, we can say that all have a period 2π ; it may have a period which is less than 2π , but 2π is actually a period.

Student: (Refer Time: 01:11).

So, if it repeats every I mean every 2π radians; so then we can say that it is a period ok. So, for our purpose we will consider all our waveforms to be periodic with period 2π radians. So, I will consider Fourier series of a periodic function; so I will not explicitly state; what is that quantity I am considering voltage or current; I will just use the general function f , it is a

function of ωt of a periodic function with period 2π in radian is. So this Fourier series is actually given by a series which has infinite number of terms.

So, the Fourier series is like this; $\frac{a_0}{2} + \sum_{h=1}^{\infty} [a_h \cos h\omega t + b_h \sin h\omega t]$; so this is the Fourier series. Now, we will not get into the theoretical aspects; whether the Fourier series converges and if it converges whether it converges to f of ωt .

So, we will assume that it does converges and converges to f of ωt ; I mean we will just as I said we are just going into the results directly. So, we will use the results; we will not get into the theory behinds, that is not part this course ok. So, the intension is to get expressions for this a_h and b_h . So, if I take a_h ; so the result is like this, a_h can be obtained from the given periodic function f of ωt ; it is $\frac{1}{\pi} \int_{c}^{c+2\pi} f(\omega t) \cos h\omega t$ with respect to ωt .

So, I have to integrate over period one period. So, I can choose any arbitrary lower limit, c is any arbitrary real number. So, I have to integrate over one period. So, the upper limit should be $c + 2\pi$ and this is applicable for h equal to 0 also then 1, 2 so on. So, for all possible values of h ; including 0 and b_h is say when h is equal to 0, I get a_0 ; a_0 is the first term ok.

So, b_h is $\frac{1}{\pi} \int_{c}^{c+2\pi} f(\omega t) \sin h\omega t$ and again integration can be between any two arbitrary limits provided the difference between these two limits is 2π . So, it can be any arbitrary c as the lower limit and upper limit will be $c + 2\pi$ and this is applicable for all values of h ; now h does not take a value 0 here; so it is 1, 2, 3 and so on ok.

So, if I take the first term $\frac{a_0}{2}$; now if you look at the equation. So, you have to look at the expression for a_h with h equal to 0; so if h is equal to 0, what happens to $\cos h\omega t$? 1. So, if you take $\frac{1}{\pi} \int_{c}^{c+2\pi} f(\omega t)$ with respect to ωt between these two limits; what do you get?

Student: Two times the average.

It is two times the average because it is dividing just by π . So, if I have divided by 2π , you would have got average. So, a_0 by 2 is the average value of f of ω o t . So, this is average value of f of ω o t . Now, in power systems we do not work with the peak values, we normally work with RMS values ok.

So, we are interested in what is happening to the fundamental component on the AC sites; say what is important on the AC side is fundamental component. What is important on the DC side is average component, rest are unwanted things; please note that. On the DC side, we only want the average value all others are unwanted, on the AC side we only want fundamental or all others are unwanted.

So, if I take the RMS value that is the root means square value of fundamental component of f of ω o t . So, what is this RMS value of fundamental component of f of ω o t ?

Student: (Refer Time: 07:05).

So, can I write that say fundamental corresponds to h equal to 1; see fundamental means it is the values obtained from this a_h ; b_h expression with h equal to 1, just as I got average with h is equal to 0. So, it is equal to a_1 ; are you familiar with this? Can I relate the fundamental component RMS value of f of ω o t and a_1 , b_1 ? So, it is a_1^2 plus.

Student: B_1 square.

B_1 square by?

Student: 2.

2; this is taken under square root; so this is the fundamental component. Now, similar to fundamental, I can get a even the harmonic component; that is corresponding to h equal to 2,

3, 4 so on. So, RMS value of we call what is known as h th order; harmonic component, h th order harmonic component of f of omega o t. So, this is similar to fundamental; only thing is in place of a 1, I have a h and in place of b 1; I have b h. So, it is under root a h square plus b h square divided by 2.

So, please note this is applicable for h say; for h is equal to 1, we say the fundamentals. See the name fundamental is for h equal to 1, for h greater than 1; we say harmonic that is a point ok. Fine, now sometimes it is easy to use some other Fourier series other than this trigonometric, this is known as trigonometric Fourier series and there is an another equivalent form which is exponential.

(Refer Slide Time: 09:05)

The slide contains the following mathematical content:

$$\sum_{h=-\infty}^{\infty} \vec{C}_h e^{jh\omega t}$$

$$\vec{C}_h = \frac{1}{2\pi} \int_c^{c+2\pi} f(\omega_s t) e^{-jh\omega_s t} d(\omega_s t)$$

$$\vec{C}_0 = \frac{a_0}{2}$$

$$\vec{C}_h = \frac{a_h - jb_h}{2}, h = 1, 2, 3, \dots$$

$$\vec{C}_h = \frac{a_{-h} + jb_{-h}}{2}, h = -1, -2, -3, \dots$$

RMS value of fundamental component of $f(\omega_s t) = \sqrt{2} |\vec{C}_1|$
RMS value of h^{th} order harmonic component of $f(\omega_s t) = \sqrt{2} |\vec{C}_h|$

The NPTEL logo is located in the top right corner of the slide.

So, the exponential Fourier series is like this; sigma c h; so to explicitly indicate that c h is a complex number; I put a arrow over it ok; c h exponential of j h omega o t. So, this

summation is taken over different values of h ; what are the values of h ? Do minus infinity to plus infinity; so it is minus infinity to plus infinity. So, here c_h is the coefficient which is appearing in the Fourier series. So, c_h can be obtained from the expression for the function f of $\omega_0 t$.

So, it is $1/2\pi$; I will straight away give the answer $\int f(\omega_0 t) e^{-jh\omega_0 t} d\omega_0 t$. So, you recall exponential of; I mean do you recall minus j , it is minus $j h \omega_0 t$; $d\omega_0 t$. So, the integration can be between any two arbitrary limits, provided the difference between the upper limit and the lower limit is 2π .

Now, this is just an alternate series which is equivalent to the trigonometric series; I now sometimes this is easy to manipulate, sometimes the trigonometric is easier to manipulate ok. So, but the many times the problem is a priori you may not know which one is easy; only after trying both, many a times after trying both will come to know one was much easier than the other or you know for the sake of completeness I am giving this.

But can we relate these coefficients in this exponential series c_h to the ones in the trigonometric series a_h and b_h ? So, if I take for an example c_0 ; what is c_0 in terms of the trigonometric series coefficients? $A_0/2$. You have to just look at the expression for the c_h and then expression; I mean look at the expression for c_0 and a_0 ; then you will easily see that c_0 is $a_0/2$.

And since a_0 is real, c_0 is real; though in general c_h is complex, c_0 happens to be real ok. Then if I take any other c_h ; say if I take h equal to say 1, 2, 3 and so on. So, can I relate c_h , a_h , b_h ? So, can I get an expression for c_h in terms of a_h and b_h ? So, it is; it may not be straight forward one can show this. So, I will just give the result it can be shown that this is equal to $a_h \cos h - b_h \sin h$ divided by 2. So, this expression is applicable for positive values of h .

Student: Also we can write a_h in terms of c_h ?

We can do that.

Student: C_h minus a_h ?

Yes we can do that ok. Now, in c_h ; h can be either 0 or positive or negative. So, we have taken c_0 and positive values of h ; we can also consider negative values of h in c_h of course. So, when it comes to the subscript h in for c_h ; h can be positive as well as negative ok. So, can I relate this to the coefficients a_h and b_h ? So, here also I can relate, but it is not a_h minus $j b_h$ or a_h I mean it is not in terms of a_h and b_h because h is negative. See, what I am trying to do is; I am trying to do this for negative values of h ; so h equal to minus 1, minus 2, minus 3 and so on.

So, in this case if I take a_h ; a_h is not existent, a_{-h} a subscript minus h . So, it is actually a_{-h} plus j times b_{-h} divided by 2; these things can be derived, I am just giving the results. So, that gives the relationship between the coefficients of the exponential series and the coefficients of the trigonometric series.

So, if I take the RMS value; so similarly I can take the RMS value and try to express it in terms of c_h ; just as I did for the trigonometric series. So, RMS value of fundamental component of f of $\omega_0 t$. So, can I write it in terms of c_h ? In fact, when I say fundamental, it is in terms of c_1 ; in terms of c_1 .

So, no if you recall or it may take some time to find out what is RMS value. So, if you recall I do not know; you have seen this result, it is the absolute value of c_1 . Please note RMS value is always a positive real number ok; it is a positive real number; so you have to take the absolute value of c_1 multiplied by root 2.

See, the contribution to the RMS value of the fundamental which comes from both c_1 and c_{-1} ; it comes from both c_1 and c_{-1} . So, similarly if I take any harmonic

component; so RMS value of h th order; harmonic component. If you are not familiar with these results you can just verify these things; please verify if you are not familiar with this.

So, if you are never studied this earlier; you have to do it ok. So, you need to do just simple I mean, I mean I integrate functions and try to show that these are the expressions for the fundamental RMS and h th order harmonic component RMS. So, similarly for the h th order harmonic component; the RMS value is root 2 into absolute value of c_h . So, again if I take any h th order harmonic component; h is of course, say when I say h th order h is positive, when I say h th order h is positive. So, the contribution is coming from both c_h and c_{-h} ok.

So, I can use either the trigonometric Fourier series or a exponential Fourier series, but if you observe both involve taking; I mean taking integral over one full period that is 2π radian, whether it is a_h , b_h or c_h . Now, many times the waveforms are so complicated longer the duration for which you have to integrate; it is more laborious. So, there are some short cuts or I mean there are some easy ways to get the expressions for a_h , b_h , c_h .

So, if essentially we are trying to calculate the values of a_h , b_h or c_h ; I can use either one of them either one. So, if I can somehow reduce the duration for which I integrate then I mean I can quickly get the values. So, it is possible when these waveforms have some sort of symmetry ok.

(Refer Slide Time: 17:31)

$f(\omega_0 t)$ is an odd function $\Leftrightarrow f(-\omega_0 t) = -f(\omega_0 t)$
 $f(\omega_0 t)$ is an even function $\Leftrightarrow f(-\omega_0 t) = f(\omega_0 t)$

NPTEL

So, there are various forms of symmetry that a periodic waveform can have; so depending on that, there are simplifications ok. So, I will just start with some definitions, I will get into the details in the next class. So, all of you have heard of this odd function? So, we say that a function f of $\omega_0 t$ is an odd function. So, what I want to say is ok; so let me give a precise definition of this.

Student: Sir, (Refer Time: 18:06).

F of $\omega_0 t$.

Student: (Refer Time: 18:08).

Is an odd function.

Student: (Refer Time: 18:14).

So, that actually means that $f(-\omega t)$ is $-f(\omega t)$. Similarly, there is one more type of symmetry $f(\omega t)$ is an even function. So, the definition of this is $f(-\omega t) = f(\omega t)$. So, if a function is odd; then we get some simplification, if the function is even; we get some simplification.

There are other types of symmetries for example, half wave symmetry, quarter wave symmetry. So, due to all these symmetries; we get some simplification in the evaluation of the integral for the a or b or c . So, we will look at all these simplifications in detail in the next class.

So, I will stop here.
