Stability Notions: Lyapunov and LaSalle's theorem Part 04

(Refer Slide Time: 00:16)

LaSalle's Invariance principle

Theorem:
Let $\Omega \subset D$ be a **compact** set that is **positively invariant**.
Let $V : D \rightarrow \mathbb{R}$ be C^1 such that $\dot{V}(x) \leq 0$ in Ω .
Let E be the set of all points in Ω where $\dot{V}(x) = 0$.
Let M be the largest invariant set in E .
Then, **Every solution starting in Ω approaches M as $t \rightarrow \infty$**
(C^1 : continuously differentiable (at least once))

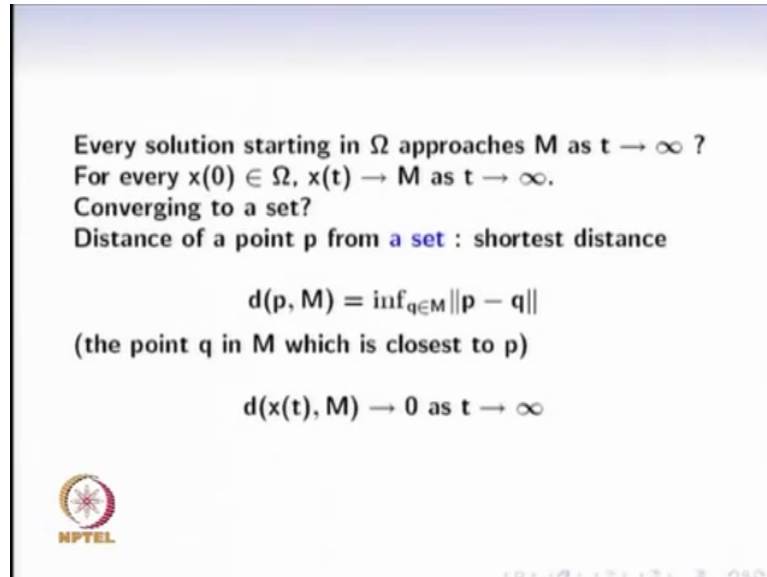

◀ ▶ ⏪ ⏩ 🔍 🔄

So we had started with LaSalle's invariance principle, the last lecture. So, let us just quickly review this. So, suppose Ω is a compact set that is positively invariant and suppose we have found a function V that is C^1 ; C^1 means differentiable and the derivatives continues such that this V satisfies \dot{V} is less than or equal to 0 on the set Ω .

For this V , we will now find a set E such that \dot{V} equal to 0 on the set E . And let M be the largest invariant set in E ; largest invariant set in E means it is invariant under the dynamics of this dynamical system, it is contained in E and it is the largest such set. In other words, any

other subset of E that has satisfies these properties is also contained in M . If these conditions are satisfied then, every solution starting in Ω approaches this set M as t tends to infinity.

(Refer Slide Time: 01:23)

Every solution starting in Ω approaches M as $t \rightarrow \infty$?
For every $x(0) \in \Omega$, $x(t) \rightarrow M$ as $t \rightarrow \infty$.
Converging to a set?
Distance of a point p from a set : shortest distance

$$d(p, M) = \inf_{q \in M} \|p - q\|$$

(the point q in M which is closest to p)

$$d(x(t), M) \rightarrow 0 \text{ as } t \rightarrow \infty$$

So, approach a set we had seen this as a definition. So, what the LaSalle's invariance principle says that, every solution starting in the set approaches M , in other words, for every initial condition that trajectory converges to M . What is the meaning of converging to a set?.

So the distance of a point p from a set is defined as the distance of p to different different points in M and the shortest such distance. So, this is a definition of distance of a point p from the set M . Now, as x evolves as a function of time, x of t is a point, and we look at the distance of x of t from the set M , and this distance decreases as t tends to infinity. That is the statement of the LaSalle's invariance principle.

So, we had already encountered the situation of the pendulum example in which, the natural energy function to take, did not satisfy strictly less than 0. So, let us do this example again.

(Refer Slide Time: 02:27)

$$\begin{aligned} \dot{x}_1 &= x_2 \\ \dot{x}_2 &= -\sin x_1 - b x_2 \end{aligned}$$

$b > 0$
(friction)

$$\ddot{x} = -\sin x - b \dot{x}$$
$$\begin{bmatrix} x_2 \\ -\sin x_1 - b x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$x_1 = 0$ & $x_2 = 0$
whether $(0,0)$
is - stable ?
- asymp. stable?

So we this is what we call as friction, this is the situation of a pendulum. The original differential equation was of second order which was equal to like this. This differential equation of second order be converted to a first order differential equation to first order differential equations by introducing x_2 .

So, x_1 is the same as x and x_2 is a derivative of x_1 and these 2 first order differential equations we will now study the equilibrium point and the stability properties of the equilibrium point.

So for this dynamical system, we will now see x_2 and \dot{x}_1 minus $b x_2$. This equal to 0 0, this gives us x_1 equal to 0 and x_2 equal to 0 as one of the equilibrium points. Of course, we could have x_1 equal to π also that corresponds to the pendulum standing upwards which we know is unstable, we can also obtain that as a conclusion by linearizing about that point and checking that the eigen values are at least one of them is in the open right of plane.

That we will keep as an exercise, what we will now check is whether this equilibrium point whether 0 comma 0 is stable; asymptotically stable. This is what we will check now. For this purpose, we will take the Lyapunov function coming as the energy of the system.

(Refer Slide Time: 04:28)

$$V(x) = (1 - \cos x_1) + \frac{x_2^2}{2}$$

$$\dot{V}(x) = \frac{\partial V}{\partial x} f(x)$$

$$= \begin{bmatrix} \sin x_1 & x_2 \end{bmatrix} \begin{bmatrix} x_2 \\ -\sin x_1 \\ -b x_2 \end{bmatrix}$$

$$\dot{V}(x) = x_2 \sin x_1 - x_2 \sin x_1 - 2 b x_2^2$$

angle x_1

So, take V of x equal to 1 minus cos of x_1 why, because this is the potential energy. So, what was our x_1 variable? This is our pendulum when it undergoes a deviation of angle x_1 .

So, this is the angle that time how much does it get raised? The amount by which it gets raised is the potential energy accumulated into the system and that turns out to be $1 - \cos x_1$; of course, multiplied by the mass and the gravitational acceleration g . But, we have a considered a model where those parameters are not arising. This can be considered as normalization of the equations or as normalization of the mass m .

There is only the potential energy, the other energy term is actually $\frac{1}{2} \dot{x}_2^2$. Let us check what happens if we take just \dot{x}_2^2 . So, this is not really energy because this is not kinetic energy second term is not kinetic energy, but twice the kinetic energy.

So, let us check what happens to $\nabla V \cdot \dot{x}$. So, this turns out to be $\nabla V \cdot \dot{x}$ times $f(x)$. And then we evaluate this, ∇V by \dot{x} is a row vector in which the first component here is a derivative of this with respect to x_1 , which is exactly $\sin x_1$ and the derivative of this with respect to x_2 , that is $2x_2$ times $f(x)$. What was the $f(x)$?

The first component was x_2 , second component was $-\sin x_1 - bx_2$ and when we multiply this product, those are like inner product we get $x_2 \sin x_1 - 2x_2^2 \sin x_1 - 2bx_2^3$. So, this is what we get as $\nabla V \cdot \dot{x}$. So, is this quantity positive or negative? That is the next thing we will investigate.

(Refer Slide Time: 06:52)

$\dot{V}(x) = -x_2 \sin x_1 - b x_2^2$

$\dot{V}(x) \neq 0$
close to $(0,0)$

$-b x_2^2 = \dot{V}(x) \leq 0$

$(0,0)$ is stable

So, we got \dot{V} of x was equal to this term is well behaved, but the other term is this is our x_1 , this is our x_2 . So, one term of course, does not change sign its always negative or equal to 0, but the other term x_1 and $x_2 \sin$ of x_1 has a same sign as x_1 close to x_1 equal to 0, but x_2 times this can change its sign depending on which quadrant it is. And hence, for small values of $x_1 x_2$; in other words, close to the origin we are not able to say that \dot{V} of x is less than or equal to 0.

This is not satisfied close to 0 comma 0. This one can check oneself. In order to check oneself, one could first ignore this particular term. Why we can ignore this term? Because this is it to put b equal to 0 just means that we have a pendulum without friction and for the pendulum without friction, we know that the system is stable.

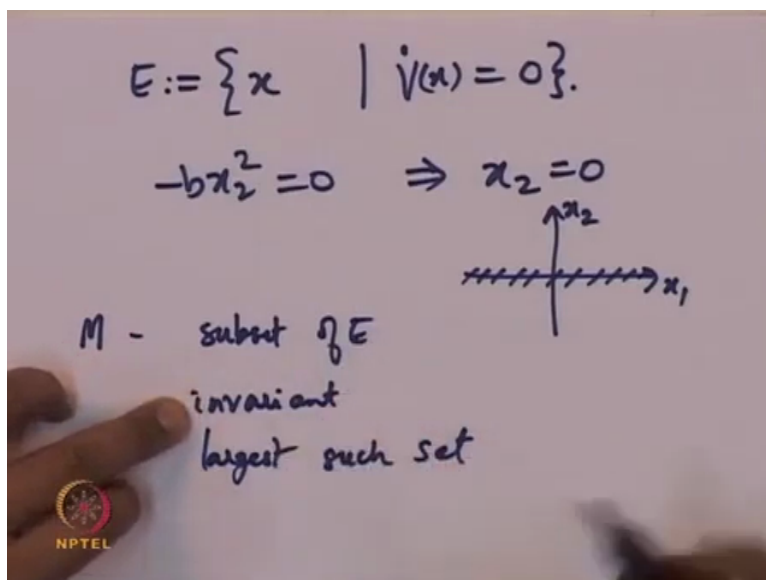

By intuition, we want to obtain that as a conclusion from the Lyapunov's theorem of stability and for that purpose, this particular quantity certainly changes sign, it will have different signs depending on x_1 , x_2 on in on each of these 4 quadrants and hence this \dot{V} does not satisfy less than or equal to 0. So, this is not a valid Lyapunov function, why? Because it is a Lyapunov candidate. It is positive definite, but it is not decreasing it is not non-increasing around the origin.

So, let us go back to our Lyapunov function and make a small change here. We will now divide this by 2. This perhaps we have already verified once. So, this now is indeed the kinetic energy. So by doing this, we do not get this 2 term here and we remove this also here because of which this term now cancels out and we have \dot{V} of x . Now it is indeed less than or equal to 0 why? Because \dot{V} of x was equal to minus $b x_2^2$.

So, this at least proves that $(0, 0)$ is stable; however, this had not helped us to prove that the origin is asymptotically stable even though, we by intuition we know that the equilibrium point is in fact, asymptotically stable because we have friction which continuously dissipates off the energy.

So, how do we obtain that? This particular function Lyapunov candidate does not help us. However, we can use LaSalle's invariance principle for the same Lyapunov function. So, construct the set E set of all x such that \dot{V} of x was equal to 0. In other words, minus $b x_2^2$ equal to 0, it gives us set of all points where x_2 is equal to 0. So, this x_2 equal to 0 is nothing but the x_1 axis. The x_1 axis is the set of all points where rate of change of the Lyapunov function is equal to 0.

(Refer Slide Time: 10:21)

So this is our set E, now we want to look at the set M which is subset of E invariant under the dynamics of the system and largest such set largest such set. Largest such set which satisfies that it is a subset of E and it is invariant under the dynamics of the system.

So, how will you find the largest such set? We will look for what values of x_1 and x_2 are subset of E and are also invariant. When we try to do this, we will automatically get the set of all $x_1 \times x_2$ points that are invariant and containing E and hence, it will be the largest such set.

(Refer Slide Time: 11:05)

The image shows a whiteboard with handwritten mathematical work. The equations are as follows:

$$x_2 = 0 \quad \dot{x}_1 = x_2$$
$$\dot{x}_2 = -\sin x_1 - b x_2$$
$$\dot{x}_1 = 0$$
$$x(t) \in E, \quad x_2(t) \equiv 0$$
$$\dot{x}_2 = 0$$
$$\Rightarrow \sin x_1 = 0$$

(0, 0) - of interest

$$M = (0, 0)$$

In the bottom left corner of the whiteboard, there is a small circular logo with a red and yellow design and the text "CAPTIVE" below it.

So, x_2 equal to 0 is requirement that the set M is contained in E . Now, we will put this in x_1 dot equal to x_2 and x_2 dot equal to minus sin x_1 minus $b x_2$. When we put x_2 equal to 0 we get x_1 dot equal to 0, we also put x_2 .

So, $x(t)$ is contained in set E which means $x_2(t)$ is equal to 0, always is uniformly equal to 0, equivalently equal to 0, identically equal to 0. These are the different ways we interpret this symbol, this equation. So, if some particular value of x has a function of time is always equal to 0, it is like a constant function which automatically means that x_2 dot is also equal to 0, identically.

So, when we put that x_2 dot equal to 0 then we also get sin of x_1 equal to 0 and this implies that sin of x_1 equal to 0 which of course, we know happens at either the vertically down position which is x_1 equal to 0 or the vertically up position which is x_1 equal to π . Since we

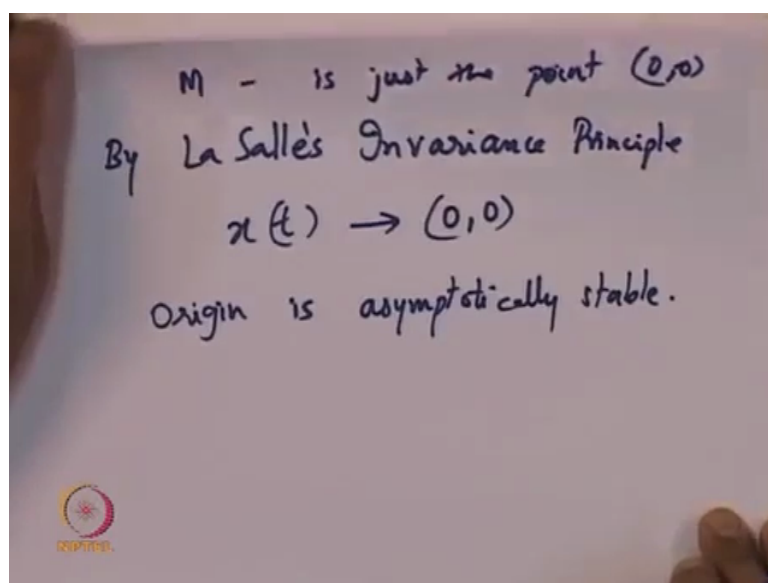

are interested about the stability properties of the position of the point $(0, 0)$, we get if this is of interest. Since we are interested at this point, we get that M is just the point $(0, 0)$.

When we ask the question inside the set E which are all those points which are invariant under the dynamics of f , the time we took the set E , which means you put the equation x_2 equal to 0 and we studied invariance by invariance for invariance we put the fact that x_2 is always equal to 0 its called which means \dot{x}_2 also equal to 0, when we substituted that back here, we got $\sin(x_1)$ also equal to 0.

This term was already 0, this term we now got equal to 0, because of which we obtained the $\sin(x_1)$ equal to 0 and which means that we this can happen at the point $(\pi, 0)$ also. The first component is equal to 0 that is a 1 of interest which is vertically down position.

So, we have obtained that the set of all invariance points that satisfies the property that is invariant and subset of E gives us only this point and this is the largest such set, any other set would not satisfy the equations. We looked at looked for all the points that satisfy the equations and got this point.

(Refer Slide Time: 14:02)

So in other words, we have obtained that M is just the set, just the point 0 comma 0 . So, what is the meaning? So, by so by LaSalle's invariance principle by LaSalle's invariance principle x of t converges to the set M which is just 0 comma 0 . So, this in other words proves that origin is not just stable, which we already concluded from the Lyapunov's theorem of stability. But we in fact, got that the origin is asymptotically stable. So, this concludes proof of the statement that the origin is asymptotically stable; by using what principle?

Not by using Lyapunov's theorem of asymptotic stability, but by using LaSalle's invariance principle which we used to conclude that the set M has just 1 point the origin. And by LaSalle's invariance principle the trajectory is x of t converge to M and hence, the origin is asymptotically stable. Now we will investigate whether the linearized system at this point is also asymptotically stable.

(Refer Slide Time: 15:34)

$$\begin{aligned} \dot{x}_1 &= x_2 \\ \dot{x}_2 &= -\sin x_1 - bx_2 \end{aligned}$$
$$\dot{x} = \begin{bmatrix} f_1(x) \\ f_2(x) \end{bmatrix}, \text{ eq. pt. } (0,0)$$
$$A = \left. \frac{\partial f}{\partial x} \right|_{x=(0,0)} = \begin{bmatrix} 0 & 1 \\ -\cos x_1 & -b \end{bmatrix}_{x=0}$$
$$= \begin{bmatrix} 0 & 1 \\ -1 & -b \end{bmatrix}, b > 0$$

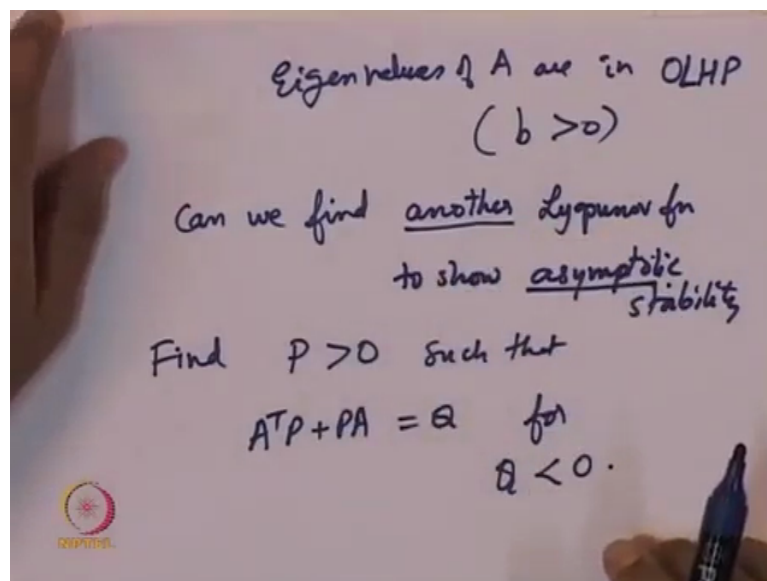

So consider again, \dot{x}_1 equal to x_2 and \dot{x}_2 equal to minus sin x_1 minus $b x_2$. So, \dot{x} is equal to this can be written as f_1 of x and f_2 of x as a vector. So, what is the linearization? We have already checked that the equilibrium point of interest is 0 comma 0 , we have checked that this is an equilibrium point. Now what is this linearized system? It is this particular matrix evaluated at x equal to 0 comma 0 . So, let us find what this matrix is.

The term that comes here is the derivative of f_1 with respect to x_1 . So, in f_1 which is this equation x_1 does not come at all. In other words, the derivative of f_1 with respect to x_1 is 0 . What is the derivative of f_1 with respect to x_2 ? That is the term that comes here that is precisely equal to 1 why? Because f_1 of x is equal to x_2 . So, derivative of f_1 of x with respect to x_2 is equal to 1 . What is the derivative of f_2 with respect to x_1 ? So, where all does x_1 appear in this equation.

It appears only here. In other words, derivative of $\sin x_1$ with respect to x_1 that is $\cos x_1$ what is the derivative of this term with respect to x_2 ? x_2 does not come here, it comes it appears only here and so we put minus b here. This as expected is a matrix, but it depends on x_1 and x_2 , it depends only on x_2 in this case. So, we are now required to evaluate this at x equal to 0 at the origin.

So, which means that in the first 2 entries $x_1 x_2$ do not appear, it appears only here when you put x_1 equal to 0 and we get minus 1. And of course, b is greater than 0. So, let us check how the eigen values of this matrix look.

Refer Slide Time: 17:52)

So, upon checking one can do the calculations and check that eigen values of A are in the open left half complex plane. One can check that by using the fact that b is greater than 0, the

eigen values of that particular matrix we wrote are both in the open left half plane, which means that the origin is asymptotically stable.

And for a linearized system if A is Hurwitz, if the origin of the linearized system has all eigen values in the open left half plane; then we know that the non-linear systems equilibrium point is also asymptotically stable.

However, that Lyapunov function could not help us with that. So, can we find another Lyapunov function? After all, the Lyapunov theorem was only a sufficient condition for stability and asymptotic stability. Since, we already know that the equilibrium point is asymptotically stable; can you find another Lyapunov function? To prove, to show asymptotic stability.

The energy function already helped us to prove stability, but we want to prove asymptotic stability. So, we will consider finding a Lyapunov function for a linearized system. In other words, find P greater than 0 such that $A^T P + P A$ is equal to Q ; for Q a negative definite matrix.

This is a problem that we will solve now. Why? Because this particular Lyapunov function for the linearized system will also help as Lyapunov function for the non-linear system. So, we can in fact, choose for linear systems because A is Hurwitz, for any Q we will be able to find such a P .

So, take Q equal to $\begin{bmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{bmatrix}$. In other words, this Q will correspond to our $V \cdot x$ of x . So, the corresponding $V \cdot x$ will turn out to be equal to $-x_1^2 - x_2^2$. Why? Because $V \cdot x$ is nothing but $x^T Q x$ for linear systems. So, when we put this particular Q we will get precisely this, and this we know is negative definite, it is strictly less than 0 for all $x \in \mathbb{R}^2$ except of course, $x_1 = 0$ and $x_2 = 0$.

(Refer Slide Time: 20:25)

Take $Q = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$

$$\dot{V}(x) = -x_1^2 - x_2^2 < 0$$
$$= x^T Q x$$

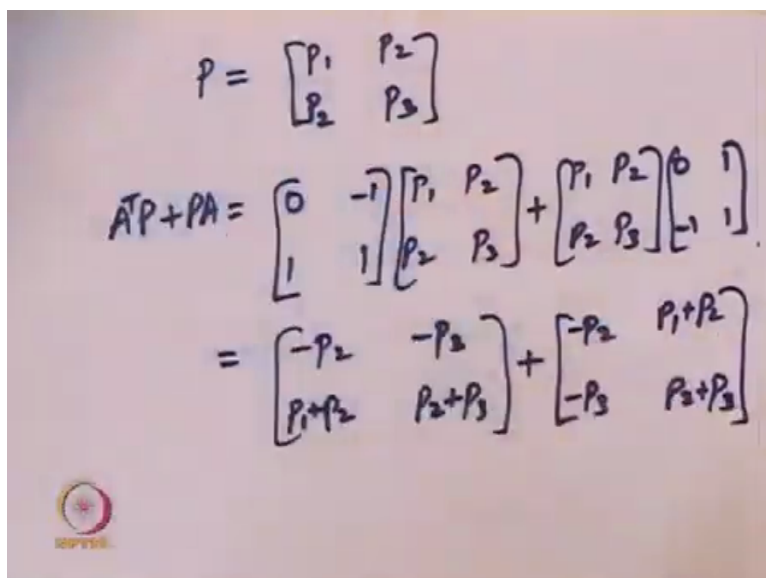

find P such that

$$A^T P + P A = Q$$
$$A = \begin{bmatrix} 0 & 1 \\ -1 & -b \end{bmatrix}, \quad b = 1$$

So, for this particular Q we will now look for a P such that, find P such that A transpose P plus $P A$ is equal to this Q because, that particular A is Hurwitz, the P that we will obtain from this equation will or will turn out to be positive definite matrix.

This is a equation that you will solve now. So, notice that A was equal to $0 \ 1$ minus 1 minus b . For the purpose of solving, we could take b equal to 1 . This is the rate at which energy decreases due to friction and this is required to be positive. So, we have taken b equal to 1 . What do we get by solving for P ?

(Refer Slide Time: 21:12)

$$P = \begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix}$$
$$A^T P + P A = \begin{bmatrix} 0 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix} + \begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ -1 & 1 \end{bmatrix}$$
$$= \begin{bmatrix} -P_2 & -P_2 \\ P_1 + P_2 & P_2 + P_3 \end{bmatrix} + \begin{bmatrix} -P_2 & P_1 + P_2 \\ -P_3 & P_2 + P_3 \end{bmatrix}$$

We can assume P has these entries. P is a symmetric matrix hence, this entry is also equal to P_{21} and P_{32} . So, when we do $A^T P + P A$, that time we get this to be equal to this is $A^T P$, what is written here is a transpose hence, $P_{11} P_{21} P_{22} P_{31}$ plus the same matrix $P_{12} P_{22} P_{23} P_{32}$ times A which was equal to $0 \ 1 \ -1 \ 1$.

So, we will now evaluate this is equal to $-P_2 \ -P_3$, this is $P_1 + P_2$ and here we have $P_2 + P_3$. This is $-P_2 \ -P_3$ and $P_1 + P_2$ and $P_2 + P_3$.

(Refer Slide Time: 22:38)

$$= \begin{bmatrix} -p_2 & -p_3 \\ p_1+p_2 & p_2+p_3 \end{bmatrix} + \begin{bmatrix} -p_2 & p_1+p_2 \\ -p_3 & p_2+p_3 \end{bmatrix}$$
$$A^T P + P A = \begin{bmatrix} -2p_2 & p_1+p_2-p_3 \\ p_1+p_2-p_3 & 2p_2+2p_3 \end{bmatrix} = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$$
$$\begin{aligned} -2p_2 &= -1 & p_2 &= \frac{1}{2} \\ p_1+p_2-p_3 &= 0 \\ 2p_2+2p_3 &= -1 & p_3 &= -\frac{1}{2} \end{aligned}$$

So now, we will equate this to Q and while doing that; so, we can add these 2 matrices to get finally, A transpose P plus P A is equal to minus 2 P 2 P 1 plus P 2 minus P 3. Here, we get the same thing P 1 plus P 2 minus P 3, and here we get 2 P 2 plus 2 P 3. So, since P was symmetric we have got this particular matrix to be symmetric and that is the reason that we should be choosing Q also to be symmetric and we have chosen Q to be equal to.

Let us find values P 1 P 2 P 3, a particular theorem we already saw claims that this system of equations is solvable. So, there are only 3 entries to 3 equations 1, 2 and 3. Why? Because this entry equal to this is the same equation as this entry equal to 0. So, let us put minus 2 P 2 equal to minus 1, P 1 plus P 2 minus P 3 is equal to 0. And finally, 2 P 2 plus 2 P 3 equal to minus 1.

So, the first equation just tells that P_2 is equal to $1 - 2P_2$ which when we substitute in the last equation we get P_3 is equal to $-1 - 2P_2$, $-2P_2$ is nothing, but -1 again which gives us P_3 equal to $-1 - 2P_2$. So, we have taken A equal to $\begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$, let us go back to this equation; we have got A equal to $\begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$ minus b and we are put b equal to 1 .

(Refer Slide Time: 24:35)

The image shows a handwritten derivation on a whiteboard. At the top, a symmetric matrix P is defined as $P = \begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix}$. Below this, the expression $A^T P + P A$ is calculated. The matrix A is given as $A = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix}$. The calculation proceeds as follows:

$$A^T P + P A = \begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix} \begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix} + \begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix} \begin{bmatrix} 0 & 1 \\ -1 & -1 \end{bmatrix}$$

$$= \begin{bmatrix} P_2 & -P_3 \\ P_1 - P_2 & P_2 - P_3 \end{bmatrix} + \begin{bmatrix} -P_2 & P_1 - P_2 \\ -P_3 & P_2 - P_3 \end{bmatrix}$$

Finally, the two matrices are added together to yield the result:

$$\begin{bmatrix} -2P_2 & P_1 - P_2 - P_3 \\ P_1 - P_2 - P_3 & 2P_2 - 2P_3 \end{bmatrix}$$

An NPTEL logo is visible in the bottom left corner of the whiteboard image.

And let us now take P equal to $\begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix}$, we have taken P to be symmetric, that is why, we have taken a same entry here. So, let us solve for $A^T P + P A$ this gives us for A^T , we will write $\begin{bmatrix} 0 & -1 \\ 1 & -1 \end{bmatrix}$ times $\begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix}$ plus the same matrix $\begin{bmatrix} P_1 & P_2 \\ P_2 & P_3 \end{bmatrix}$ times A which is equal to $\begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$ and then, we solve this.

So, this when we do, we get $-2P_2$ $P_1 - P_2 - P_3$ and $P_2 - P_3$ plus this particular matrix product when we evaluate, we get $-2P_2$ $P_1 - P_2 - P_3$ $2P_2 - 2P_3$

minus P_3 and when we add these 2 matrices we get $2P_2 - P_1 - P_2 - P_3$, $P_1 - P_2 - P_3$, $P_1 - P_2 - P_3$ and finally, $2P_2 - 2P_3$.

So, this matrix we finally got is nothing but $A^T P + P A$. Now, we will equate this to Q . So, we had already taken. So, notice that this matrix is symmetric because P we have because we have taken P to be symmetric, this matrix has been obtained to be symmetric and hence, it is important that this matrix be equal to a Q which also should be assumed to be symmetric.

(Refer Slide Time: 26:36)

$$\begin{array}{l}
 \left. \begin{array}{l} -p_3 \\ -2p_3 \end{array} \right\} \quad \begin{array}{l} -2p_2 = -1 \\ p_1 - p_2 - p_3 = 0 \\ 2p_2 - 2p_3 = -1 \end{array} \quad Q = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \\
 \hline
 p_2 = \frac{1}{2} \\
 2p_3 = 2p_2 + 1 = 2 \\
 p_1 = p_2 + p_3 = 2.5
 \end{array}$$

So, we have taken Q to be equal to $\begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$. So, when we equate this matrix to Q then we have it appears like 4 equations, this entry equal to minus 1, this entry equal to 0, this entry equal to 0 is again the same equation. So, it is not really 4 equations, but 3. What is the last equation? This entry equal to minus 1. So, these 4 equation now we will write here. So,

we have $-2P_2 = -P_1 - P_2 - P_3 = 0$ and $2P_2 - 2P_3 = -1$.

So, the first equation gives us $P_1 = 2P_2$ which, when we substitute into the last equation, we get $2P_3 = 2P_2 + 1$ which was equal to 2, when we put $P_2 = 0.5$, here we get 2. And these $P_1 = 2P_2 = 1$ and $P_3 = 2 - 2P_2 = 1$ when we substitute into the second equation, we get $P_1 = P_2 + P_3 = 2.5$.

(Refer Slide Time: 28:04)

$$P = \begin{bmatrix} 2.5 & 0.5 \\ 0.5 & 2 \end{bmatrix}$$

$P > 0?$

$$P_{11} = 2.5 > 0$$
$$\det P = 2 \times 2.5 - 0.5^2 = 5 - 0.25 = 4.75 > 0$$

So, what is our matrix P? As a result of this, the matrix P was equal to $P_1 = 2.5$, $P_2 = 0.5$, which is the same entry here and finally, $P_3 = 1$. So, the claim is that this matrix P that we have obtained is positive definite because, A was Hurwitz and Q was negative definite.

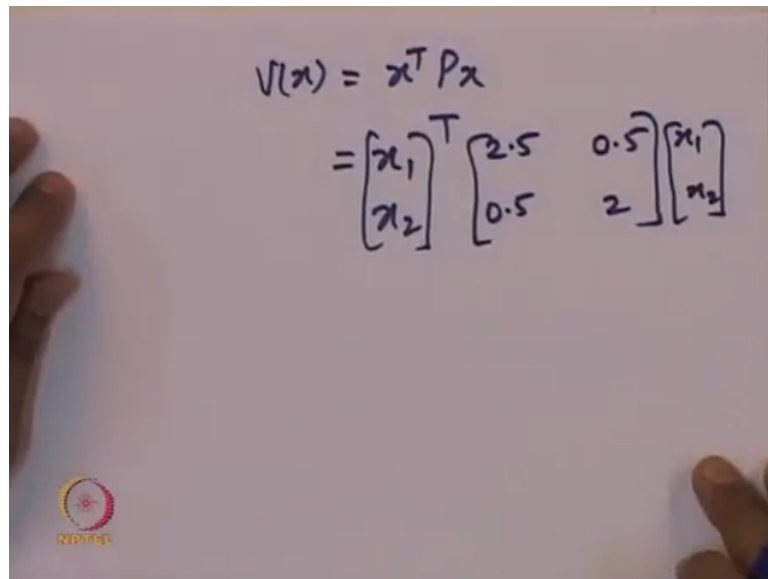

We can check this. So, P greater than 0, how will you check this? One way to check that a matrix is positive definite is that all the principal minors, all the leading principal minors. So, for a square symmetric matrix this is a 1 by 1 minor, it is a principle minor because it is has a symmetric rows and columns taken to construct that submatrix and only the leading ones.

So, we take only this now, and every such matrix we take and look at the determinant and each of these determinants should be a positive number, that is a necessary and sufficient condition for this matrix P to be a positive definite matrix. So, let us do the check for this.

Here, we have to take only 2 determinants the first 1 by 1 determinant is nothing but 2.5, P 1 1, the first submatrix is equal to 2.5 that is greater than 0. What about the determinant of the whole matrix? The next leading principle minor is nothing but the whole matrix P . The determinant of the whole matrix is 2 into 2.5 minus 0.5 square, which is equal to 5 minus 0.25, it is equal to 4.75, that is positive.

So, because both the first leading 1 by 1 minor and the second leading 2 by 2 minor are both positive determinant, this means that the matrix P is positive definite. So, if we had taken the Lyapunov function coming from this P for the linearized system.

(Refer Slide Time: 30:12)

$$V(x) = x^T P x$$
$$= \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}^T \begin{bmatrix} 2.5 & 0.5 \\ 0.5 & 2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

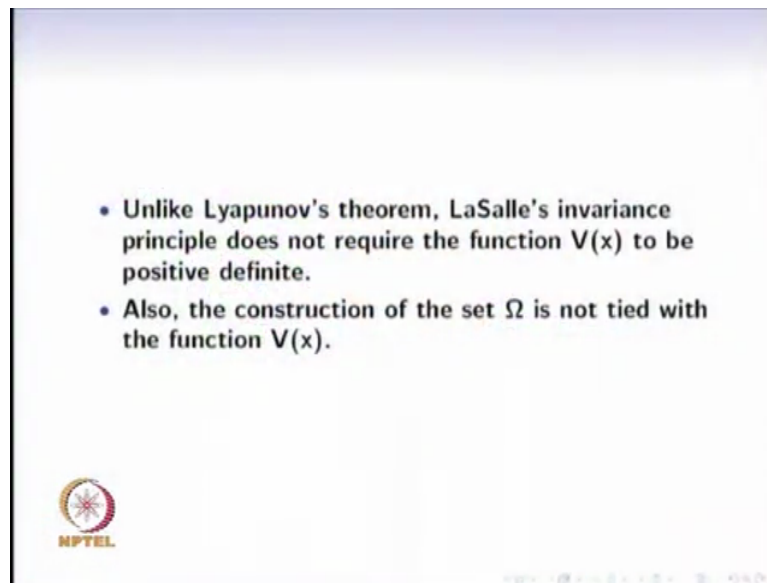

So, what is the Lyapunov function? It is $x^T P x$ in which P was in which the matrix P was the one that we just now obtained. If you take this as the Lyapunov function, and the origin turns out to be asymptotically stable by Lyapunov's theorem of asymptotic stability.

And the same Lyapunov function will also help us improving asymptotic stability of the non-linear systems equilibrium point which happens to be the origin again, but if we had started with this Lyapunov function, then we would not have required LaSalle's invariance principle, because a Lyapunov function theorem itself would have claimed, stated that the equilibrium point is asymptotically stable.

Unlike the energy function, unlike the physical energy that we had taken, which helped us to prove only stability. By Lyapunov's theorem of stability. So, this completes Lyapunov analysis, we have seen some solved examples also. We can have another set of problems which

we will use as exercises. We will now move on to the next topic which is about periodic orbits. Why? Because periodic orbits are an important part in the context of building oscillators.

(Refer Slide Time: 31:37)

So, before we move to that topic there is one other slide that we had skipped, so, the LaSalle's invariance principle which we saw in detail and also saw in example is different from Lyapunov's theorem in 2 ways. The first way is, unlike the Lyapunov theorem, the LaSalle's invariance principle does not require the function V to be positive definite.

Notice that we did not assume that V was positive definite. Second, the positive invariant set that we had constructed in the proof of the Lyapunov theorem that set Ω was constructed using the Lyapunov function V , here we are assuming that we already have a positive invariant set.

In fact, it is that is the reason that we are not assuming V as positive definite; because, on a compact set ω we are V always achieves its minimum and we can subtract that minimum from the function V here, by which we can always obtain another function V that indeed is positive definite.

(Refer Slide Time: 32:36)

Barbashin and Krasovskii's theorems

$\dot{x} = f(x)$ and $f(0) = 0$, i.e. $x = 0$ is an equilibrium point.

Let $V : D \rightarrow \mathbb{R}$ be a continuously differentiable positive definite function on a domain D containing the origin.
 $V(x) > 0$ for all $x \in D$ except $x = 0$
 $\dot{V}(x) \leq 0$ on D
 $M = \{x \in D \mid \dot{V}(x) = 0\}$
 Suppose, the only solution that can remain inside M is $x(t) \equiv 0$, then
 0 is asymptotically stable
 Further, if $V : \mathbb{R}^n \rightarrow \mathbb{R}$ is radially unbounded, then 0 is globally asymptotically stable

We will also see an application of LaSalle's invariance principle; so, there are well-known results that are, that turn out to be a special case of the LaSalle's invariance principle. So, one of them is Barbashin-Krasovskii's theorems, what is the statement of the theorem?.

So, suppose \dot{x} is equal to f of x is a system, in which x can have many components, x is an element of \mathbb{R}^n and suppose the origin is an equilibrium point. Suppose, there exists a function

V from a domain D to \mathbb{R} which is continuously differentiable, and suppose V is positive definite function; in other words, V of x is greater than 0 for all x except origin x equal to 0.

And also V satisfies that it is less than or equal to 0, on the domain D . Construct the set M that is made up of all the points where \dot{V} is equal to 0. Suppose, this particular M has a property that the only solution that can remain inside M is $x(t)$ identically equal to 0, then the origin is asymptotically stable.

Notice that this is precisely the situation that had happened for the pendulum example with friction. So, the Barbashin-Krasovskii's theorem is a more general statement to this effect. What can we speak say about global asymptotic stability of that equilibrium point we just now claim to be asymptotically stable?.

If V is radially unbounded further, in addition to the above assumptions, if V is also radially unbounded, then the origin is in fact, globally asymptotically stable. So, this particular theorem we already saw for the case of a pendulum, as well as asymptotic stability is concerned. Of course, a pendulum example it is not globally asymptotically stable simply because there are other equilibrium points.

However, the Barbashin-Krasovskii's theorem says that if V were radially unbounded, then the origin is in fact, globally asymptotically stable. One can check that the Lyapunov function V we had used for the case of the pendulum example with friction, that is not going to be radially unbounded. Otherwise, the origin there would have been globally asymptotically stable account to this theorem.
