**Week - 07**  
**Observability and Minimal Realization**  
**Lecture – 36**  
**Output feedback and observability**

So, welcome to the 7th week of the Linear Dynamical Systems. So, in this week we will discuss about the Observability and Minimal Realization Problem.

(Refer Slide Time: 00:22)

The slide is titled "Outline of Week 7" and lists the following topics:

- 1 Observability and its tests
- 2 Kalman Decomposition
- 3 Detectability and its tests
- 4 Minimal Realization

The slide also features the IIT Mandi logo and the NPTEL logo in the top right corner. A small video inset in the bottom right corner shows the professor, Prof. Tushar Jain, speaking.

So, the outline of this week is we will start with the concepts of observability and its tests. Then we will discuss about the Kalman decomposition which will include the controllability and the observability analysis in combined. Third, we will see the weaker concept than

observability that is detectability and we will also see the test. And finally, we will conclude with the minimal realization.

(Refer Slide Time: 00:51)

Observability

**Motivation: Output Feedback**

Consider the continuous-time LTI system

$$\begin{bmatrix} \dot{x} = Ax + Bu, & y = Cx + Du, \end{bmatrix} \quad x \in R^n, u \in R^k, y \in R^m \quad (\text{CLTI})$$

We know that if the pair  $(A, B)$  is stabilizable, then there exists a state feedback law

$$u = -Kx \quad (\text{Control law})$$

that asymptotically stabilize the system (CLTI), i.e., for which  $(A - BK)$  is a stability matrix.

**Issue**

However, when only the output  $y$  can be measured (as opposed to the whole state  $x$ ), the (Control law) cannot be implemented.

**Possible solution**

In principle, this difficulty can be overcome if it is possible to reconstruct the state of the system based on its measured output and perhaps also on the control input that is applied.

So, observability is basically related to the problem of the controllability what we had discuss in the 3rd or 4rth week. So, if you recall the problem of the controllability that we want to ensure that whether there exists a control law, such that I can steer my state trajectory from some  $x$  of  $t$  naught to some  $x$  of  $t$  1, ok. So, here let us say if a continuous time LTI system is given by  $A, B, C, D$  matrices, where  $x$  is  $n$ -dimensional,  $u$  is  $k$  dimensional and  $y$  is  $m$ -dimensional.

So, we know that if the pair  $A$  comma  $B$  is a stabilizable then there exists a state feedback law which is given by  $u$  is equal to minus  $k$  times  $x$ , which we have defined as control law. That

asymptotically stabilize the system, this one, that is for which this matrix  $A - BK$  which is the closed loop matrix is a stability matrix, ok.

Now, if the pair  $A, B$  is controllable then we can achieve much more performance specification by designing this state feedback gain matrix  $K$ , ok. Now, here you would see that for computing the control law  $u$  you need the information of the state signal. So, however, when only the output  $y$  can be measured as opposed to the whole state  $x$  the control law cannot be implemented, right because if we do not have the direct measurement of the signal  $x$  and you only have the direct measurement of the signal  $y$  then you cannot implement this control law, you need the information about the state signal.

So, possible solution in principle this difficulty can be overcome, if it is possible to reconstruct the state of the system based on its measured output and perhaps also on the control input that is being applied, ok.

So, the idea here is now the only measured signal in this system is the external signals which we have defined earlier as the input to the plant and the output of the plant;  $x$  is an internal signal, right. So, now if it is possible to reconstruct the signal  $x$  based on the available measurements  $u$  and  $y$ , then it would be still possible to use this control law, ok. Now, there other ways of constructing this  $x$  also.

(Refer Slide Time: 03:39)

Observability

### Motivation: Output Feedback

When the matrix  $C$  is invertible, instantaneous reconstruction of  $x$  from  $y$  and  $u$  is possible by solving the output equation for  $x$

$$x(t) = C^{-1}(y(t) - Du(t)).$$

$y = Cx + Du$   
 $y - Du = Cx$   
 $\tilde{y} = Cx$   
 $x = C^{-1}\tilde{y}$

Trivially speaking, now, see the output equation; the output equation is given by  $y$  is equal to  $Cx$  plus  $Du$ , ok. The signal  $u$  is already a measured signal, so I can take this  $Du$  on to the left hand side. So, let us say  $y$  minus  $Du$  is equal to  $Cx$  and let us denote this  $y$  minus  $Du$  because  $D$  matrix is known to me  $u$  signal I am measuring and similarly  $y$ , so I can denote this as some  $\tilde{y}$  is equal to  $Cx$ , ok.

Now, if  $C$  is invertible that is to say the inverse of the  $C$  exist then I can perfectly reconstruct the signal  $x$  as  $C$  inverse of,  $C$  inverse times  $\tilde{y}$ . Here the information of the matrix  $C$  is also known to me  $\tilde{y}$  I have computed by the signals  $y$  and  $u$ . So, if  $C$  is invertible that is the inverse of the  $C$  exist, then I can directly compute the signal  $x$ , ok.

(Refer Slide Time: 04:43)

Observability

### Motivation: Output Feedback

When the matrix  $C$  is invertible, instantaneous reconstruction of  $x$  from  $y$  and  $u$  is possible by solving the output equation for  $x$

$$\hat{x}(t) = C^{-1}(y(t) - Du(t)).$$

However, this would be possible only if the number of outputs was equal to the number of states ( $C$  is a square matrix).

When the number of outputs is strictly less than number of states, instantaneous reconstruction of  $x$  is not possible, but it may still be possible to reconstruct the state from the output  $y(t)$  and input  $u(t)$  over the time interval  $[t_0, t_1]$ .

$$\hat{g}(s) = \frac{n(s)}{d(s)} = \frac{y(s)}{u(s)}$$

But this is only possible if the number of outputs is equal to the number of states, right thus  $C$  the first restriction is that  $C$  should be a square matrix. And this square matrix could be possible, if we have the number of output as equal to the number of states. But when the number of outputs is strictly less than number of states which is always possible or which is mostly possible, the instantaneous reconstruction of  $x$  is not possible, right. But it may still be possible to reconstruct the state again by taking the signals  $y$  and  $u$  over some time interval  $t_0$  to  $t_1$ , right.

So, this you can visualize this, say for example, if we many times we have considered a single input single output system which is of some ratio of polynomial numerator and denominator, which is nothing but  $y$  of  $s$  and  $u$  hat of  $s$ . Here we know that the output is  $1$  and the input is

also 1. Now, depending on the degree of the polynomial of the denominator, we have so far seen the dimension of the state matrix A matrix.

So, if let us say if  $d(s)$  is of some the degree of the polynomial of  $d(s)$  is 3 then in that case we would have the number of state variable  $n=3$ , ok, but we know that the output is 1. So, in that case we cannot have the invertibility of the C matrix. But what we want to know that whether it is possible by collecting the signals  $y$  and  $u$  we can construct somehow this  $x$  or not, ok.

So, in this week we will study some conditions that under what conditions we can say that we can reconstruct this signal  $x$ , how we will going to reconstruct it we will discuss in the last week of this course.

(Refer Slide Time: 06:53)

Observability

### Motivation: Output Feedback

When the matrix  $C$  is invertible, instantaneous reconstruction of  $x$  from  $y$  and  $u$  is possible by solving the output equation for  $x$

$$x(t) = C^{-1}(y(t) - Du(t)).$$

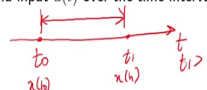

However, this would be possible only if the number of outputs was equal to the number of states ( $C$  is a square matrix).

When the number of outputs is strictly less than number of states, instantaneous reconstruction of  $x$  is not possible, but it may still be possible to reconstruct the state from the output  $y(t)$  and input  $u(t)$  over the time interval  $[t_0, t_1]$ .

Two formulations are usually considered.

- 1. **Observability** refers to determining  $x(t_0)$  from the *future* inputs and outputs,  $u(t)$  and  $y(t), t \in [t_0, t_1]$ .
- 2. **Constructibility** refers to determining  $x(t_1)$  from the *past* inputs and outputs,  $u(t)$  and  $y(t), t \in [t_0, t_1]$ .

So, before proceeding forward we will use two formulations one is the observability and second is the constructability. The observability refers to determine the initial condition of the state at  $t_0$  from the future inputs and outputs  $u(t)$  and  $y(t)$ , observed at during the interval  $t_0$  to  $t_1$ , ok.

So, let us say we let us talk about the time axis. So, this is  $t$ , this is  $t_0$  and this is  $t_1$  and here we have taken  $t_1$  greater than  $t_0$ , ok. Now, start let us say, between this interval we have observed the input output signal. So, using this information of input output signal if I am computing the value of  $x$  at  $t_0$  then we call it the observability. If we are computing the value of  $x$  at  $t_1$ , we would call it the constructability, ok.

(Refer Slide Time: 08:02)

Observability

### Unobservable Subspace

Consider the continuous-time LTV system

$$\dot{x} = A(t)x + B(t)u, \quad y = C(t)x + D(t)u, \quad x \in R^n, u \in R^k, y \in R^m \quad (\text{CLTV})$$

We know that the system's state  $x_0 := x(t_0)$  at time  $t_0$  is related to its input and output on the interval  $[t_0, t_1]$  by the variation of constants formula:

$$y(t) = C(t)\phi(t, t_0)x_0 + \int_{t_0}^t C(t)\phi(t, \tau)B(\tau)u(\tau)d\tau + D(t)u(t), \quad \forall t \in [t_0, t_1],$$

where  $\phi(\cdot)$  denotes the system's state transition matrix.

To study the system's observability, we need to determine under which conditions we can solve

$$\tilde{y}(t) = C(t)\phi(t, t_0)x_0, \quad \forall t \in [t_0, t_1]$$

for the unknown  $x_0 \in R^n$ , where

$$\tilde{y}(t) = y(t) - \int_{t_0}^t C(t)\phi(t, \tau)B(\tau)u(\tau)d\tau - D(t)u(t), \quad \forall t \in [t_0, t_1].$$

So, then we define the unobservable subspace similarly to what we have defined during the controllability week, where we have defined some subspaces and then did some

characterizations. So, consider the continuous time, linear time varying system when all  $A$ ,  $B$ ,  $C$ ,  $D$  matrices are time varying with the same dimension. So, we know that the system state  $x$  at  $t$  is related to its input and output on the interval  $t_0$  to  $t$  by the variation of constants formula what we had seen in the first week. This is the solution of the LTV system,  $y(t)$  is equal to  $C(t)$  times state transition matrix  $\Phi(t, t_0)$ ,  $x(t_0)$  and this integrant plus  $D(t)u(t)$ , ok.

So, to study the systems observability, we need to determine under which conditions we can solve this equation. So, this equation is similarly to what we had seen earlier. So, this is the solution, right. Now, if you pay attention to this term in this term you have information of all the signals and the functions,  $u$  we are measuring the signal;  $B$ ,  $\Phi$  and  $C$  you can compute depending on the system matrices, ok.

Similarly, here we know about  $u$  and  $D$  is already known to us. So, if I take this complete term again onto the left hand side and defined as  $\tilde{y}$  which is  $y(t)$  minus this whole term for all  $t$  during this interval  $t_0$  to  $t$ , I can specify it as  $\tilde{y}$  is equal to  $C$  into  $\Phi$  into  $x(t_0)$ , where  $C$  is my output matrix and  $\Phi$  is the state transition matrix, right. And I want to find out  $x(t_0)$  say for example, ok.

Again, I cannot take the inverse of this part because I know  $\Phi$  is non-singular in the square matrix, but since it has been pre multiplied by the output matrix which is still possible that it could be a non-square matrix. So, the overall matrix here would still be a non-square and I cannot take the inverse of this one to directly compute this  $x(t_0)$ , ok. But we will see some spaces some subspaces and for which we can characterize that for what or for what elements  $x(t_0)$  the we can construct this signal, ok.

(Refer Slide Time: 10:40)

Observability

## Unobservable Subspace

Definition (Unobservable subspace)

Given two times  $t_1 > t_0 \geq 0$ , the *unobservable subspace* on  $[t_0, t_1]$ , i.e.,  $\mathcal{UO}[t_0, t_1]$  consists of all states  $x_0 \in \mathbb{R}^n$  for which

$$C(t)\phi(t, t_0)x_0 = 0, \quad \forall t \in [t_0, t_1].$$

So, the first of all we will define unobservable subspace that given two times  $t_1$  greater than  $t_0$  which is greater than or equal to 0, the unobservable subspace on  $t_0$  to  $t_1$  be denoted by this by the scalar graphic  $\mathcal{UO}$ , unobservable  $t_0$  comma  $t_1$  consists of all states  $x_0$  for which this condition is satisfied, right. So, there is a direct implication from the previous equation by which we can define the unobservable subspace. So, let us see.

So, this is the equation we had seen earlier  $y$  tilde is equal to  $C\phi$  into  $x_0$ , ok. Now, if my  $y$  tilde which is basically the subtraction of the output and a function containing input if this subtraction becomes equal to 0, then all those  $x_0$  would become, would belong to my unobservable subspace because I cannot observe them at, all right. So, this is what this definition says that if the  $C\phi x_0$  becomes equal to 0 then all those  $x_0$  for which

this equation is satisfied would belong or would make me or would give me the unobservable subspace, ok.

(Refer Slide Time: 12:08)

Observability

Unobservable Subspace

Properties (Unobservable subspace)

Suppose we are given two times  $t_1 > t_0 \geq 0$  and an input/output pair  $u(t), y(t), [t_0, t_1]$ .

① When a particular initial state  $x_0 = x(t_0)$  is compatible with the input/output pair, then every initial state of the form

$$\tilde{x} = x_0 + x_u, \quad x_u \in \mathcal{UO}[t_0, t_1]$$

is also compatible with the same input/output pair. This is because

$$\begin{cases} \tilde{y} = C(t)\phi(t, t_0)x_0, & \forall t \in [t_0, t_1] \\ 0 = C(t)\phi(t, t_0)x_u, & \forall t \in [t_0, t_1] \end{cases} \quad +$$

$$\Rightarrow \tilde{y} = C(t)\phi(t, t_0)(x_0 + x_u) \quad \forall t \in [t_0, t_1].$$

Now, let us see some properties of this unobservable subspace. So, suppose we are given two times again  $t_1$  greater than  $t_0$  and an input output pair  $u, y$  over this time interval  $t_0$  to  $t_1$ . Now, when a particular initial state  $x_0$  that is  $x$  defined at  $t_0$  is compatible with the input output pair then every initial state of the form, so you can define this as  $\tilde{x}$ , that  $\tilde{x}$  is defined as  $x_0$  plus  $x_u$ , where  $x_u$  belongs to that unobservable subspace, right.

So,  $\tilde{x}$  would also be compatible with the same input output pair. Why? Because say for example,  $x_0$  belongs to that input output pair then it means that  $\tilde{y}$  will not be 0 for  $x_0$ . So, I can write  $\tilde{y}$  is equal to  $C$  into  $\phi$  into  $x_0$  and since  $x_u$  belongs to the

unobservable subspace it would have, we would have  $0 = C\phi(t, t_0)x_0 + \int_{t_0}^t C\phi(t, \tau)u(\tau)d\tau$ . So, if I sum these two equations, I would get  $y(t) = C\phi(t, t_0)x_0 + \int_{t_0}^t C\phi(t, \tau)u(\tau)d\tau$ . So, I cannot differentiate or I mean to say this one would also belong to the same input/output pair.

(Refer Slide Time: 13:28)

Observability

## Unobservable Subspace

**Properties (Unobservable subspace)**

Suppose we are given two times  $t_1 > t_0 \geq 0$  and an input/output pair  $u(t), y(t), [t_0, t_1]$ .

- When the unobservable subspace contains only the zero vector, then there exists at most one initial state that is compatible with the input/output pair<sup>1</sup>.

This is because if two different states  $x_0, \bar{x}_0 \in \mathbb{R}^n$  were compatible with the same input/output pair, i.e.,

$$\begin{cases} \dot{y} = C(t)\phi(t, t_0)x_0, & \forall t \in [t_0, t_1] \\ \dot{y} = C(t)\phi(t, t_0)\bar{x}_0, & \forall t \in [t_0, t_1] \end{cases}$$

$$\Rightarrow 0 = C(t)\phi(t, t_0)(x_0 - \bar{x}_0) \quad \forall t \in [t_0, t_1],$$

+

and therefore  $x_0 - \bar{x}_0 \neq 0$  would have to belong to the unobservable subspace.

---

<sup>1</sup>Because of this property, it is possible to uniquely reconstruct the state of an observable system from (future) inputs/outputs.

The second property which is the most important one, again considered two times  $t_1$  greater than  $t_0$  and the input/output pair  $u, y$  over this interval. So, when the unobservable subspace contains only the  $0$  vector, then there exists at most one initial state that is compatible with the input/output pair, right. So, because of this property only it is possible to uniquely reconstruct the state of an observable system from future input and output. Let us see.

So, consider two different states  $x_0$  and  $\bar{x}_0$ , which are compatible with the same input/output pair. So, I can write the same equation for  $x_0$  and  $\bar{x}_0$ , right.

Subtracting these two equations I would get 0 onto the left hand side and C phi times x naught minus x naught bar.

Now, this equation means that this x naught minus x naught bar which is not equal to 0 belongs to the unobservable space subspace, because this equation has been satisfied as we have seen the definition. So, there exists at most one initial state, they cannot exist two initial states, right. So, that is why it helps us to uniquely reconstruct the state of the system.

(Refer Slide Time: 14:53)

Observability

### Unobservable Subspace

The above properties motivate the following definition.

**Definition (Observable system)**

Given two times  $t_1 > t_0 \geq 0$ , the system (CLTV) is *observable* whenever its unobservable subspace contains only the zero vector; i.e.,  $\mathcal{U}[t_0, t_1] = 0$ .

The matrices  $B(\cdot)$  and  $D(\cdot)$  play no role in the definition of the unobservable subspace; therefore one often simply talks about the unobservable subspace or the observability of the system

$$\dot{x} = A(t)x, \quad y = C(t)x \quad x \in \mathbb{R}^n, y \in \mathbb{R}^m \quad (\text{A}\dot{\text{C}}\text{-CLTV})$$

So, the above properties motivate the following definition. So, given two times  $t_1$  greater than  $t_0$  the system continuous time linear time varying system is observable whenever its unobservable subspace contains only the 0 vector, right. Meaning to say that there does not exist  $x_0$  for which that previous equation is satisfied, right. So, the matrices B and D, we had seen that they do not play any role in the definition of the unobservable subspace. So,

we will generally talk about the unobservability or the unobservable subspace or observability of the system or let us say the pair  $A$  comma  $C$ , which we define pair  $AC$  of CLTV.

(Refer Slide Time: 15:49)

Observability

## Unconstructible Subspace

The "future" system's state  $x_1 := x(t_1)$  at time  $t_1$  can also be related to the system's input and output on the interval  $[t_0, t_1]$  by the variation of constants formula:

$$y(t) = C(t)\phi(t, t_1)x_1 + \int_{t_1}^t C(t)\phi(t, \tau)B(\tau)u(\tau)d\tau + D(t)u(t), \quad \forall t \in [t_0, t_1]$$

**Definition (Unconstructible subspace)**

Given two times  $t_1 > t_0 \geq 0$ , the *unconstructible subspace* on  $[t_0, t_1]$ , i.e.,  $\mathcal{UC}[t_0, t_1]$  consists of all states  $x_1$  for which

$$C(t)\phi(t, t_1)x_1 = 0, \quad \forall t \in [t_0, t_1].$$

Now, similarly we can define the unconstructible subspace. Now, here we had seen only the value of the state at some particular time based on that we have define the unobservable and unconstructible subspaces. So, here the future system states  $x_1$  defined as  $x$  of  $t_1$  at time  $t_1$  can also be related to the systems input and output on the interval by the variation of constants formula by using this one, the only difference is that instead of  $t_0$  now we are having  $t_1$  at every places, ok.

And by keeping the same definition that the unconstructible subspace on the time interval  $t_0$  to  $t_1$  consists of all states  $x_1$  for which this equation is satisfied. Again, the differences of the  $t_0$  and the value of  $x$  at  $t_1$  which we have defined as  $x_1$ , ok. So, all those  $x$

naught would belong to the unobservable subspace, if this equation is satisfied for some  $x_1$  and  $\phi(t, t_0)x_1$  with  $\phi(t, t_0)x_1 = 0$  and now for all  $x_1$  and  $\phi(t, t_0)x_1 = 0$  if this equation is satisfied, then we call it the unconstructible subspace, ok.

(Refer Slide Time: 17:08)

Observability

## Unconstructible Subspace

**Properties(Unconstructible subspace)**

Suppose we are given two times  $t_1 > t_0 \geq 0$  and an input/output pair  $u(t), y(t), t \in [t_0, t_1]$ .

- ➊ When a particular final state  $x_1 = x(t_1)$  is compatible with the input/output pair, then every final state of the form
 
$$x_1 + x_u, \quad x_u \in \mathcal{UC}[t_0, t_1]$$
 is also compatible with the same input/output pair.
- ➋ When the unconstructible subspace contains only the zero vector, then there exists at most one final state that is compatible with the input/output pair.

**Definition (Constructible system)**

Given two times  $t_1 > t_0 \geq 0$ , the system (CLTV) is *constructible* whenever its unconstructible subspace contains only the zero vector, i.e.,  $\mathcal{UC}[t_0, t_1] = \{0\}$ .

The property would remain the same, that when a particular final state  $x_1$  is compatible with the input output pair then every final state of the form  $x_1$  plus  $x_u$  because  $x_1$  is compatible and  $x_u$  belongs to the unconstructible. So, the summation of that would also belong to or would be compatible with the same input output pair, right. Second when the unconstructible subspace contains only the 0 vector, then there exists at most one final state that is compatible with the input output pair and this ensures the uniqueness also.

So, if you talk about now the system the constructible system that the system is constructible whenever its unconstructible subspace contains only the zero vector that is UC is equal to 0, right, that there is no element in that subspace.

(Refer Slide Time: 18:06)

Observability

**Physical example**

**Parallel interconnection:**  
 Consider the below interconnection of two systems with states  $x_1, x_2 \in \mathbb{R}^n$ .  
 The overall system corresponds to following state space model

$$\dot{x} = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} x + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u, \quad y = \begin{bmatrix} C_1 & C_2 \end{bmatrix} x$$

where we chose for state  $x := \begin{bmatrix} x_1^T & x_2^T \end{bmatrix}^T \in \mathbb{R}^{2n}$ .

We can see one example let us talk about the parallel interconnection. So, this is one system, let us call its system 1 and this is system 2, and we are supplying the common input to both the system and taking output as the summation of  $y_1$  plus  $y_2$ . So, you can represent this parallel interconnection by using this combined state space equation where  $x$  is  $x_1$  and  $x_2$  and  $A_1, A_2$  would be in the diagonal elements and  $B_1, B_2$  and this would be  $u$  which is missing, ok. And  $y$  is equal to  $C_1, C_2 x$ , right.

(Refer Slide Time: 18:49)

Observability

### Physical example

**Parallel interconnection:**  
 Consider the below interconnection of two systems with states  $x_1, x_2 \in \mathbb{R}^n$ .  
 The overall system corresponds to following state space model

$$\dot{x} = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} x + \begin{bmatrix} B_1 \\ B_2 \end{bmatrix} u, \quad y = [C_1 \ C_2] x$$

where we chose for state  $x := [x_1^T \ x_2^T]^T \in \mathbb{R}^{2n}$ . The output is given by

$$y(t) = C_1 e^{A_1 t} x_1(0) + C_1 e^{A_2 t} x_2(0) + \int_0^t (C_1 e^{A_1(t-\tau)} B_1 + C_2 e^{A_2(t-\tau)} B_2) u(\tau) d\tau.$$

When  $A_1 = A_2 = A$  and  $C_1 = C_2 = C$ , we have

$$y(t) = C e^{A t} (x_1(0) + x_2(0)) + \int_0^t C e^{A(t-\tau)} (B_1 + B_2) u(\tau) d\tau.$$

This shows that, solely by knowing the input and output of the system, we cannot distinguish between initial states for which  $x_1(0) + x_2(0)$  is the same.

So, the output you can also write by computing  $y_1$  which would be the  $y_1$  of this system and  $y_2$  of this system and I can sum them up to compute  $y$ , and you can write it as  $C_1$ . It should be this  $C_1$ , and this integral is  $y_1$ . And this should  $C_2$ , so this and this would be your  $y_2$ , right.

Now, suppose if your  $C_1$  and  $C_2$  become equal to  $C$  and  $A_1$  and  $A_2$  become equal to  $A$ , then this complete equation I can write this as this one, ok. And you would notice that that by knowing only the input and output we cannot distinguish between the initial stage for which  $x_1(0) + x_2(0)$  is the same, right. Whatever I would compute let us say all the conditions of the observability has been satisfied and I have been able to compute this  $x$ , but that  $x$  would be the summation of both the states. And the concept of observability says that I need to know

x 1 and x 2 individually and here I am getting the summation. So, this whenever you are having this parallel interconnection the system might not be observable always, ok.

Observability

Subspace characterization using Gramians

Definition (Observability and Constructibility Gramians)

Given two times  $t_1 > t_0 \geq 0$ , the *observability* and *constructibility* Gramians<sup>1</sup> of the system (CLTV) are defined by

$$W_O(t_0, t_1) := \int_{t_0}^{t_1} \Phi(\tau, t_0)^T C(\tau)^T C(\tau) \Phi(\tau, t_0) d\tau,$$

$$W_{Cn}(t_0, t_1) := \int_{t_0}^{t_1} \Phi(\tau, t_1)^T C(\tau)^T C(\tau) \Phi(\tau, t_1) d\tau.$$

<sup>1</sup>Both Gramians are symmetric positive-semidefinite  $n \times n$  matrices.

So, similarly to what we had seen during the controllability week that we had introduce the Gramians and we did the subs the characterization of the discussed subspaces using those Gramians.

So, first of all we will define the observability and the constructability Gramians says, that given two times  $t_1$  greater than  $t_0$  the observability and constructability Gramians of the system are defined by this  $W_O$  and  $W_{Cn}$  over  $t_0$  to  $t_1$ , ok. So, this here  $\Phi$  is the state transition matrix,  $C$  is the output matrix and yes. So, both Gramians here are symmetric, positive, semi-definite, square matrix of dimension  $n$ , ok.

Observability

### Subspace characterization using Gramians

**Theorem (Unobservable and Unconstructible subspaces)**

Given two times  $t_1 > t_0 \geq 0$ ,

$\mathcal{UO}[t_0, t_1] = \ker W_O(t_0, t_1), \quad \mathcal{UC}[t_0, t_1] = \ker W_{Cn}(t_0, t_1).$

**Proof.**

From the definition of the observability Gramian, for every  $x_0 \in \mathbb{R}^n$ , we have

$$x_0^T W_O(t_0, t_1) x_0 = \int_{t_0}^{t_1} x_0^T \Phi^T(\tau, t_0) C^T(\tau) C(\tau) \Phi(\tau, t_0) x_0 d\tau$$

$$+ \int_{t_0}^{t_1} \|C(\tau) \Phi(\tau, t_0) x_0\|^2 d\tau. \quad \text{if } x_0 \in \ker A, \quad A n = 0$$

Therefore

$$x_0 \in \ker W_O(t_0, t_1) \implies C(\tau) \Phi(\tau, t_0) x_0 = 0, \quad \forall \tau \in [t_0, t_1]$$

$$\implies x_0 \in \mathcal{UO}[t_0, t_1] \text{ from definition.}$$

Conversely,

$$x_0 \in \mathcal{UO}[t_0, t_1] \implies C(\tau) \Phi(\tau, t_0) x_0 = 0, \quad \forall \tau \in [t_0, t_1]$$

$$\implies x_0 \in \ker W_O(t_0, t_1).$$

For the second implication, we are using the fact, for any given positive-semidefinite matrix  $W, x^T W x = 0$  implies that  $W x = 0$ . This implication is not true for nonsemidefinite matrices. A similar argument can be made for the unconstructible subspace. □

So, based on this Gramians we can give our first results which basically characterizes these subspaces. So, the first trivial method is to find out all those  $x$  naught for which the previous equation is satisfied that is  $C \phi$  into  $x$  naught is equal to 0.

Now, if you want to characterize the entire subspace that subspace is basically given by the Kernel of the control the observability Gramian matrix  $W_o$ , ok. Similarly, the unconstructible subspace is equivalent to the Kernel of the constructibility Gramian  $W_{Cn}$ , ok. We can see a quick proof.

So, from the definition of the observability Gramian we can write it in the first of all we can write it in the quadratic form as  $x$  naught transpose  $W_o$  into  $x$  naught and then substituting the value the matrix  $W_o$  here, I would get this one. And then using the property of the norms and the quadratic forms I can compress this long expression into thus squared norm of this

term, ok. So, this is basically  $C \phi x$  and this is the transpose. So, I can write it the squared norm of this term, right.

Now, let us see because now we want to show that if an element belongs to this unobservable subspace then that element would also belong to the Kernel of the observability Gramian, ok. So, let us see. So, therefore,  $x$  belonging to the Kernel of this  $W_o$  implies, so if you remember that the if an element belongs to this Kernel of any matrix  $A$ , then it means that  $A$  of  $x$  is equal to 0, ok.

So, if  $x$  belongs to this Kernel of  $W_o$ , then what would happen?  $W_o x$  would be 0. Now,  $W_o x$ , if I put  $W_o x = 0$  then this left hand side term would become equal to 0, right. Now, if this term becomes equal to 0 and this is the integral of the squared norm and this would be only 0 if this inside the norm is itself equal to 0.

So, this implies that  $x$  belonging to the Kernel of this observability Gramian implies that this term would be equal to 0 and by taking the definition of the unobservable subspace that all those  $x$  would definitely belong to that unobservable subspace. So, all those elements which belong to this subspace would definitely belong to this unobservable subspace meaning to say that this equivalence would be satisfied, ok.

Now, see the reverse one. Now, if we have  $x$  belonging to the unobservable subspace meaning to say this equation would satisfy, right. Now, if this equation is satisfied and I put it here it means the quadratic form itself is 0. Now, if the quadratic form itself is 0 it implies that this is equal to 0. Now, there is and under some condition this this implication would hold, that is to say that satisfying this one implies  $x$  would belong to the Kernel of this observability matrix and this is only possible because  $W$  is a positive semi definite matrix. Now, if  $W$  is some non-semi definite matrix then this implication will not hold, ok. So, a similar argument can be made for the unobservable subspace.
