Observability

**Subspace characterization using Gramians**

**Theorem (Unobservable and Unconstructible subspaces)**

Given two times  $t_1 > t_0 \geq 0$ ,

$$\mathcal{UO}[t_0, t_1] = \ker W_O(t_0, t_1), \quad \mathcal{UC}[t_0, t_1] = \ker W_{C_n}(t_0, t_1).$$

**Proof.**

From the definition of the observability Gramian, for every  $x_0 \in \mathbb{R}^n$ , we have

$$\begin{aligned} x_0^T W_O(t_0, t_1) x_0 &= \int_{t_0}^{t_1} x_0^T \Phi^T(\tau, t_0) C^T(\tau) C(\tau) \Phi(\tau, t_0) x_0 d\tau \\ &= \int_{t_0}^{t_1} \|C(\tau) \Phi(\tau, t_0) x_0\|^2 d\tau. \end{aligned}$$

Therefore

$$\begin{aligned} x_0 \in \ker W_O(t_0, t_1) &\implies C(\tau) \Phi(\tau, t_0) x_0 = 0, \quad \forall \tau \in [t_0, t_1] \\ &\implies x_0 \in \mathcal{UO}[t_0, t_1] \text{ from definition.} \end{aligned}$$

Conversely,

$$\begin{aligned} x_0 \in \mathcal{UO}[t_0, t_1] &\implies C(\tau) \Phi(\tau, t_0) x_0 = 0, \quad \forall \tau \in [t_0, t_1] \\ &\implies x_0 \in \ker W_O(t_0, t_1). \end{aligned}$$

For the second implication, we are using the fact, for any given positive-semidefinite matrix  $W$ ,  $x^T W x = 0$  implies that  $Wx = 0$ . This implication is *not true* for nonsemidefinite matrices. A similar argument can be made for the unconstructible subspace. □

So, far we had seen about the subspace characterization using Gramians. So, whatever the result we have obtained in this theorem, we can directly apply to determine whether the system is observable or not.

(Refer Slide Time: 00:27)

Observability

### Subspace characterization using Gramians

This result provides a first method to determine whether a system is observable or constructible, because the kernel of a square matrix contains only the zero vector when the matrix is nonsingular.

**Theorem (Observable and Constructible systems)**

Suppose we are given two times  $t_1 > t_0 \geq 0$ .

- 1 The system (CLTV) is observable if and only if  $\text{rank} W_O(t_0, t_1) = n$ .
- 2 The system (CLTV) is constructible if and only if  $\text{rank} W_{Cn}(t_0, t_1) = n$ .

So, this results not only provides a first method to provide to determine whether a system is observable or constructible, but it also provides the characterization of the sub spaces which we would use in the later concepts. So, this Gramian has a direct implication. So, let us see. So, it says that the unobservable sub space from  $t_0$  to  $t_1$  is equivalent to the kernel of this a square matrix  $W_O$  dimension  $n$ .

Now, if we go back to the dimension the definition of the observable observability, it says the unobservable subspace should contain zero vector right then the system is observable. Now if it contains the zero vector then the kernel of that matrix should be 0 it should not contain any vector and this will only possible if the matrix itself is non singular. Because in the previous theorem we had seen that the Gramian matrix is a positive semi definite ok.

So, based on this we have the next result that suppose we are given 2 times  $t_1$  greater than  $t_0$  greater than equal to 0 the system continuous time LTV is observable if and only if the rank of the observability Gramian is equal to  $n$  similarly its for the constructible system. In satisfying this rank condition means that the square matrix are nonsingular ok.

(Refer Slide Time: 02:11)

Observability  
**Gramian-based reconstruction**

Consider the continuous-time LTV system

$$\dot{x} = A(t)x + B(t)u, \quad y = C(t)x + D(t)u, \quad x \in \mathbb{R}^n, u \in \mathbb{R}^k, y \in \mathbb{R}^m. \quad (\text{CLTV})$$

We have seen that the system's state  $x_0 := x(t_0)$  at time  $t_0$  is related to its input and output on the interval  $[t_0, t_1]$  by

$$\tilde{y}(t) = C(t)\Phi(t, t_0)x_0, \quad \forall t \in [t_0, t_1],$$

where

$$\tilde{y}(t) = y(t) - \int_{t_0}^t C(t)\Phi(t, \tau)B(\tau)u(\tau)d\tau - D(t)u(t), \quad \forall t \in [t_0, t_1].$$

Now we can again use this Gramian to actually reconstruct the state. So, consider again this LTV system given by this pair ABCD, we have seen that the system state  $x$  at  $t$  is related to its input and output on the interval this one and this we have obtained from the variation of constants formula we had seen earlier. So,  $\tilde{y}$  is nothing, but a subtraction of the terms containing the output signal and the function containing the input signal ok.

So, basically we want to construct this  $x$  and we had seen earlier difficulties that if  $C$  is a non singular matrix or its is not invertible, then I cannot compute this  $x$ , but

using the Gramians we would say we would see that how we could do the reconstruction of the  $x$  naught ok.

(Refer Slide Time: 03:11)

Observability

Gramian-based reconstruction

$$\tilde{y}(t) = C(t)\Phi(t, t_0)x_0$$

Premultiplying by  $\Phi(t, t_0)^T C(t)^T$  and integrating between  $t_0$  and  $t_1$  yields

$$\int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T \tilde{y}(t) dt = \int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T C(t) \Phi(t, t_0) x_0 dt,$$

which can be written as

$$\int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T \tilde{y}(t) dt = W_O(t_0, t_1) x_0,$$

So, we will premultiply by this vector where phi is a straight translation matrix and C is the output matrix and so, let us write it here once again. So, that there is no confusion we have y tilde this is the question we had obtained. Now if I pre multiply this above equation by phi transpose and C transpose and then integrated I would obtain on the left hand side phi transpose C transpose y tilde dt and on the right hand side I would obtain phi transpose C transpose multiplied by C phi and x naught and here x naught is a constant. So, I can take it inside the integral or outside the integral right.

Now, keeping the left hand side as it is and notice this whole term this is nothing, but your observability Gramian. So, I can replace this on the right hand side as observability Gramian multiplied by  $x$  naught ok.

(Refer Slide Time: 04:25)

Observability

### Gramian-based reconstruction

Premultiplying by  $\Phi(t, t_0)^T C(t)^T$  and integrating between  $t_0$  and  $t_1$  yields

$$\int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T \tilde{y}(t) dt = \int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T C(t) \Phi(t, t_0) x_0 dt,$$

which can be written as

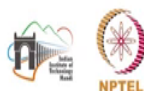

$$\int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T \tilde{y}(t) dt = W_O(t_0, t_1) x_0,$$

If the system is observable,  $W_O(t_0, t_1)$  is invertible, and we conclude that

$x_0 = W_O(t_0, t_1)^{-1} \int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T \tilde{y}(t) dt,$

which allows us to reconstruct  $x(t_0)$  from the future inputs and outputs on  $[t_0, t_1]$ . A similar construction can be carried out to reconstruct  $x(t_1)$  from past inputs and outputs for reconstructible systems.

+

Now, taking the property of the observability which says that the observability Gramian is invertible or it is full (Refer Time: 04:36) then it is possible to take the its inverse which is a square matrix to perfectly reconstruct this  $x$  naught using this formula ok. Similar construction can be carried out to reconstruct  $x$  of  $t_1$  from past inputs and outputs for reconstructible systems right.

(Refer Slide Time: 04:56)

Observability

### Gramian-based reconstruction

**Theorem (Gramian-based reconstruction)**

Suppose we are given two times  $t_1 > t_0 \geq 0$  and an input/output pair  $u(t), y(t), \forall t \in [t_0, t_1]$ .

- 1 When the system (CLTV) is observable
 

$$\hat{x}(t_0) = W_{CO}(t_0, t_1)^{-1} \int_{t_0}^{t_1} \Phi(t, t_0)^T C(t)^T \tilde{y}(t) dt,$$

where

$$\tilde{y}(t) := y(t) - \int_{t_0}^t C(t)\Phi(t, \tau)B(\tau)u(\tau)d\tau - D(t)u(t), \quad \forall t \in [t_0, t_1].$$
- 2 When the system (CLTV) is constructible
 

$$\hat{x}(t_1) = W_{CO}(t_0, t_1)^{-1} \int_{t_0}^{t_1} \Phi(t, t_1)^T C(t)^T \tilde{y}(t) dt,$$

where

$$\tilde{y}(t) := y(t) - \int_{t_1}^t C(t)\Phi(t, \tau)B(\tau)u(\tau)d\tau - D(t)u(t), \quad \forall t \in [t_0, t_1].$$

So, we have the immediate result that suppose we are again given 2 times  $t_1 > t_0$  and an input output pair  $u, y$  for all time  $t$  belonging to a  $t_0$  and  $t_1$ . So, when the system CLTV is observable we can compute  $x$  of  $t_0$  using this formula where  $y$  tilde is given by this one and when the system CLTV is constructible again we can compute this  $x$  of  $t_1$  using this constructible Gramian.

(Refer Slide Time: 05:32)

Observability  
**Discrete-time Case**

Consider the discrete time LTV system

$$x(t+1) = A(t)x(t) + B(t)u(t), \quad y(t) = C(t)x(t) + D(t)u(t), \quad (\text{DLTV})$$

for which the system's state  $x_0 := x(t_0)$  at time  $t_0$  is related to its input and output on the interval  $t_0 \leq t \leq t_1$  by the variations of constant formula,

$$y(t) = C(t)\Phi(t, t_0)x_0 + \sum_{\tau=t_0}^{t-1} C(t)\Phi(t, \tau)B(\tau)u(\tau) + D(t)u(t) \quad \forall t_0 \leq t \leq t_1$$

**Definition (Unobservable and unconstructible subspaces)**

Given two times  $t_1 > t_0 \geq 0$ , the *unobservable subspace* on  $[t_0, t_1]$ ,  $\mathcal{UO}[t_0, t_1]$  consists of all states  $x_0$  for which

$$C(t)\Phi(t, t_0)x_0 = 0, \quad \forall t_0 \leq t < t_1.$$

The *unconstructible subspace* on  $[t_0, t_1]$ ,  $\mathcal{UC}[t_0, t_1]$  consists of all states  $x_1$  for which

$$C(t)\Phi(t, t_1)x_1 = 0, \quad \forall t_0 \leq t < t_1.$$

Now generalize whatever the results we had seen we its in the continuous time domain, we can generalize all those results and the discrete time domain also. So, consider this ABCD again the time varying matrices where t is now an integer. So, by using the variation of constants formula we had seen in the first week the solution of the discrete time LTV system; where again phi is a state transition matrix and ABCD or CBD are the parameter matrices of this LTV system ok.

So, along the same line of the continuous time domain we can define these two sub spaces unobservable and unconstructible on t naught to t 1 consisting of all states x naught for which C phi x naught is equal to 0 right because again I can take this entire part onto the left hand side and then denoted its y tilde so I would have y tilde is equal to C phi x naught and if my C phi x naught becomes equal to 0.

So, for all those  $x_0$  for which we have  $C \phi x_0 = 0$  would belong to the unobservable subspace. Similarly the unconstructible subspace on  $t_0$  to  $t_1$  consists of all states  $x_1$  for which this equation is satisfied.

Now, in the continuous time domain and the discrete time domain we had seen a key difference in computing the state transition matrix that in the continuous time domain we can compute the state transition matrix in both the directions ok, but in the discrete time domain we had seen some limitations, when this limitation arises because if you pay attention to this state transition matrix which is  $\phi(t, t_0)$ , where  $t$  is from  $t_0$  to  $t_1$  which means that I need to compute the state transition matrix backward in time.

Say for this one  $\phi(t, t_0)$  where  $t$  is  $t_0$  to  $t_1$  again. So, the initial point is  $t_0$  and the final point is  $t$  which is greater than  $t_0$ . So, I am computing here state transition matrix forward in time, but here my initial point is  $t_1$  and  $t$  is from  $t_0$  to  $t_1$ .

(Refer Slide Time: 08:08)

Observability

### Discrete-time Case

**Attention!**

The definition of the discrete-time unconstructible subspace requires a backward-in-time state transition matrix  $\Phi(t, t_1)$  from time  $t_1$  to time  $t \leq t_1 - 1 < t_1$ . This matrix is well defined only when

$$x(t_1) = A(t_1 - 1)A(t_1 - 2) \cdots A(\tau)x(\tau), \quad t_0 \leq \tau \leq t_1 - 1$$

can be solved for  $x(t)$ , i.e., when all the matrices  $A(t_0), A(t_0 + 1), \dots, A(t_1 - 1)$  are nonsingular. When this does not happen, the unconstructibility subspace cannot be defined.

**Definition (Observable and Constructible systems)**

Given two times  $t_1 > t_0 \geq 0$ , the system (DLTV) is *observable* whenever its unobservable subspace contains only the zero vector, and it is *constructible* whenever its unconstructible subspace contains only the zero vector.

So, here I need to compute the state transition matrix backward in time and this is only possible that this matrix is well defined only when I compute  $x$  of  $t_1$  which is represented by this one for all  $x$   $t$ s then and this is only possible when all the matrices at different time from  $t_0$  to  $t_1 - 1$  are nonsingular. This is the same restriction what we had seen in the first week while computing the solution of the discrete time scenario. So, when this does not happen the unconstructibility subspace cannot be defined ok, but there are no limitations in the unobservable subspace right.

So talking about the systems, now given two times  $t_1 > t_0 \geq 0$  the system DLTV is observable whenever its unobservable subspace contains only the zero vector and it is constructible whenever its unconstructible subspace contains only the zero vector and the

same definitions, but we had used while understanding the concepts of the continuous time case.

(Refer Slide Time: 09:21)

Observability  
Discrete-time Case

**Definition (Observability and constructibility Gramians)**

Given two times  $t_1 > t_0 \geq 0$ , the *observability and constructibility Gramians* of the system (AC-DLTV) are defined by

$$W_O(t_0, t_1) := \sum_{\tau=t_0}^{t_1-1} \Phi(\tau, t_0)^T C(\tau)^T C(\tau) \Phi(\tau, t_0),$$

$$W_{C_n}(t_0, t_1) := \sum_{\tau=t_0}^{t_1-1} \Phi(\tau, t_1)^T C(\tau)^T C(\tau) \Phi(\tau, t_1)$$

**Theorem (Unobservable and Unconstructible subspaces)**

Given two times  $t_1 > t_0 \geq 0$ ,

$$\mathcal{U}\mathcal{O}[t_0, t_1] = \ker W_O(t_0, t_1), \quad \mathcal{U}\mathcal{C}[t_0, t_1] = \ker W_{C_n}(t_0, t_1)$$

The Gramians the Gramians would remain the same with just the summation would appear instead of the integration and also the time is in integer instead of the real number. So, this is the Gramians the observability Gramian and this is the controllability Gramian and the key results which characterizes these sub spaces in terms of the Gramian is given by it remains the same in also the derivation remains the same.

(Refer Slide Time: 09:56)

Observability  
Discrete-time Case

**Theorem (Gramian-based reconstruction)**

Suppose we are given two times  $t_1 > t_0 \geq 0$  and an input/output pair  $u(t), y(t), t_0 \leq t < t_1$ .

- 1 When the system (DLTV) is observable

$$x(t_0) = W_{O_n}(t_0, t_1)^{-1} \sum_{t=t_0}^{t_1-1} \Phi(t, t_0)^T C(t)^T \bar{y}(t).$$

- 2 When the system (DLTV) is constructible

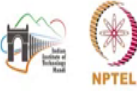

$$x(t_1) = W_{C_n}(t_0, t_1)^{-1} \sum_{t=t_0}^{t_1-1} \Phi(t, t_1)^T C(t)^T \bar{y}(t).$$

So, we will not go into the derivation of these results ok. Now in the discrete time case if I want to reconstruct this is the formula, you can use it if your system is observable to reconstruct  $x(t_0)$  if your system is constructible, you can compute  $x(t_1)$  using this formula where we had seen key use of the Gramians the respective Gramians ok.

(Refer Slide Time: 10:26)

Observability

## Duality (LTI)

Consider the continuous-time LTI system

$$\dot{x} = Ax + Bu, \quad y = Cx + Du, \quad x \in \mathbb{R}^n, \quad u \in \mathbb{R}^k, \quad y \in \mathbb{R}^m. \quad (\text{CLTI})$$

So far we have shown the following

The system (CLTI) is controllable  $\iff \text{rank}W_C(t_0, t_1) = n,$

where  $W_C(t_0, t_1) := \int_{t_0}^{t_1} e^{A(\tau-t_0)} B B^T e^{A^T(t_1-\tau)} d\tau.$

The system (CLTI) is observable on  $[t_0, t_1] \iff \text{rank}W_O(t_0, t_1) = n,$

where  $W_O(t_0, t_1) := \int_{t_0}^{t_1} e^{A^T(\tau-t_0)} C^T C e^{A(t_1-\tau)} d\tau.$

Now, the next concept in this observability is duality. So, duality is a very important concept by which we will see our relationship between the results what we have derived during the controllability and also the test for the observability for the LTI system. So, let us recall first of all the controllable systems for the LTI specifically. So, given these ABCD matrices note that here that  $x$  is  $n$  dimensional  $u$  is  $k$  and  $y$  is  $m$  ok.

We will give some importance to that in the next slide that is so, far we have seen that the CLTI is controllable if and only if the rank of the controllability Gramian is equal to  $n$  where controllability Gramian is defined by this ok. Now, the CLTI is observable if the rank of the observability Gramian is this. So, here we made use of the  $AB$  matrices and here we made use of the  $AC$  matrices right.

(Refer Slide Time: 11:55)

Observability

### Duality (LTI)

Suppose we construct the following dual system.

$$\dot{\bar{x}} = A^T \bar{x} + C^T \bar{u}, \quad \bar{y} = B^T \bar{x} + D^T \bar{u}, \quad \bar{x} \in \mathbb{R}^n, \bar{u} \in \mathbb{R}^m, \bar{y} \in \mathbb{R}^k.$$

(DUAL-CLTI)

For this system we have the following.

The system (DUAL-CLTI) is controllable  $\iff \text{rank} \bar{W}_C(t_0, t_1) = n,$

where  $\bar{W}_C(t_0, t_1) := \int_{t_0}^{t_1} e^{A^T(\tau-t_0)} C^T C e^{A(\tau-t_0)} d\tau.$  †

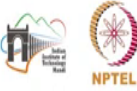

The system (DUAL-CLTI) is observable on  $[t_0, t_1]$   $\iff \text{rank} \bar{W}_O(t_0, t_1) = n,$

where  $\bar{W}_O(t_0, t_1) := \int_{t_0}^{t_1} e^{A(\tau-t_0)} B B^T e^{A^T(\tau-t_0)} d\tau.$

Recall

$$\bar{W}_C(t_0, t_1) := \int_{t_0}^{t_1} e^{A^T(\tau-t_0)} B B^T e^{A^T(\tau-t_0)} d\tau$$

$$\bar{W}_O(t_0, t_1) := \int_{t_0}^{t_1} e^{A^T(\tau-t_0)} C^T C e^{A(\tau-t_0)} d\tau.$$

Now, I will define a dual system in the sense that the  $\bar{x}$  would be of  $n$  dimensional, but  $\bar{y}$  would be the dimension of the output. So, if you see previously we have  $y$   $n$  number of outputs but in my dual system I am representing it by  $\bar{u}$   $m$  number of  $\bar{u}$  and  $k$  number of  $\bar{y}$  and I represent my dual system is  $\bar{x}$  dot or by  $A$  transpose  $C$  transpose  $B$  transpose and  $D$  transpose where,  $C$  transpose in this dual systems becomes my input matrix and  $B$  transpose here becomes my output matrix and the state matrix and the input matrix and the output equation are taken as that transposes ok. Now let us see the controllability and observability for this dual system.

So, for this representation again I need the conditions would remain the same it just I need to compute the controllability Gramian and the observability Gramian ok. So, by taking  $A$  transpose and  $C$  transpose to compute the controllability Gramian I would obtain this one ok.

Now for observability I need to see A transpose and B transpose and using that pair I can write the observability Gramian in terms of that AB matrices ok.

Now try to see the relationship between this dual CLTI and the actual LTI system. So, recall these controllability Gramian and the observability Gramian which we had seen in the last slide. So, I put this thing on the same slide so, that we can easily visualize the relationship between the controllability of the original system and the observability of the dual system. So, this WC and WO are the gramians of the original system and this WC bar and WO bar are the gramians of the dual system ok.

So, here WC you see the a matrix the pair AB matrix. So, this WC and this WO bar basically is the same right. Similarly WO that is the controllability Gramian of the original system and the controllability Gramian of the dual system also remains the same.

(Refer Slide Time: 14:36)

Observability

### Duality (LTI)

**Theorem (Duality controllability/observability)**

Suppose we are given two times  $t_1 > t_0 \geq 0$

- 1 The system (CLTI) is controllable if and only if the system (DUAL-CLTI) is observable on  $[t_0, t_1]$ .
- 2 The system (CLTI) is observable on  $[t_0, t_1]$  if and only if the system (DUAL-CLTI) is controllable.

**Theorem (Duality reachability/constructability)**

Suppose we are given two times  $t_1 > t_0 \geq 0$

- 1 The system (CLTI) is reachable if and only if the system (DUAL-CLTI) is constructible on  $[t_0, t_1]$ .
- 2 The system (CLTI) is constructible on  $[t_0, t_1]$  if and only if the system (DUAL-CLTI) is reachable.

**Theorem (Duality)**

The pair  $(A, B)$  is controllable if and only if the pair  $(A', B')$  is observable.

So, based on this we have the immediate result that the system CLTI is controllable if and only if the dual system is observable right. Similarly the CLTI is observable if and only if that dual system is controllable. So, they both are equivalent the result would remain the same for the reachability or the duality between the reach ability and the constructability.

So, we can also summarize these two results in the form that the pair if we only talk about the pair. That pair AB is controllable if and only if the pair A transpose B transposes observable and this is only valid for the LTI system we will see that how these conditions varies for the LTI system.

(Refer Slide Time: 15:36)

Observability

### Observability Tests

Consider the LTI systems

$$\dot{x}/x^+ = Ax, \quad y = Cx, \quad x \in \mathbb{R}^n, y \in \mathbb{R}^m \quad (\text{AC-LTI})$$

From the duality theorems, we can conclude that a pair  $(A, C)$  is observable if and only if the pair  $(A^T, C^T)$  is controllable.

This allows us to use *all* previously discussed tests for controllability to determine whether or not a system is observable.

To apply the controllability matrix test to the pair  $(A^T, C^T)$ , we construct the corresponding controllability matrix

$$\mathcal{C} = [C^T \quad A^T C^T \quad (A^T)^2 C^T \quad \dots \quad (A^T)^{n-1} C^T]_{(kn) \times n} = \mathfrak{D}^T$$

where  $\mathfrak{D}$  denotes the *observability matrix* of the system (AC-LTI), which is defined by

$$\mathfrak{D} := \begin{bmatrix} C \\ CA \\ \vdots \\ CA^{n-1} \end{bmatrix}$$

So now moving forward to the observability test. So, we had seen that there exists there is a duality between the controllability and observability. Meaning to say that whatever the results we had obtained for the controllability they would be directly applicable to analyze the

observability. So, we will list out all the results of the observability without going into the proofs of those results.

So, consider the LTI system. So, here we use the notations so, that we can represent the discrete time and the continuous time with the same state equations. So, from the duality theorems we can conclude that a pair  $AC$  is observable if and only if that pair  $A^T C^T$  is controllable or because in the previous we had seen  $AB$  is controllable if and only if  $A^T B^T$  is observable it just the pair.

So, here we have replaced  $B$  by  $C$  and the results would remain the same. So, this allows us to use all the previously discussed tests for controllability to determine whether or not the system is observable particularly for the LTI system. So, this we can visualize also.

So on this pair  $A^T C^T$  if I compute the controllability matrix this would be given by this one of dimension  $kn \times n$ . Now I can define this matrix as the transpose of the observability matrix where my observability matrix is given by this one ok. So, the controllability matrix of the pair  $A^T C^T$  given by this and whatever the matrix I have obtained after doing some simplification, I defined the observability matrix as this one. That is to say the controllability matrix is actually equivalent to the transpose of the observability matrix ok.

(Refer Slide Time: 17:48)

### Observability Tests

Since  $\text{rank}C = \text{rank}D^T = \text{rank}D$ , we obtain the following tests.

**Theorem (Observability tests)**

The following statements are equivalent.

- 1 The system (AC-LTI) is observable.
- 2  $\text{rank}D = n$ .
- 3 No eigenvector of  $A$  is in the kernel of  $C$ .
- 4  $\text{rank} \begin{bmatrix} A - \lambda I \\ C \end{bmatrix} = n, \quad \forall \lambda \in \mathbb{C}$ .

**Theorem (Lyapunov test for observability)**

Assume that  $A$  is a stability matrix/Schur stable. The system (AC-LTI) is observable if and only if there is a unique positive-definite solution  $W$  to the Lyapunov equation

$$A^T W + W A = -C^T C \quad / \quad A^T W A - W = -C^T C$$

Moreover, the unique solution to this equation is

$$W = \int_0^\infty e^{A^T \tau} C^T C e^{A \tau} d\tau = \lim_{t_1 \rightarrow t_0 \rightarrow \infty} W_O(t_0, t_1)$$

$$/ \quad W = \sum_{\tau=0}^{\infty} (A^T)^\tau C^T C A^\tau d\tau = \lim_{t_1 \rightarrow t_0 \rightarrow \infty} W_O(t_0, t_1).$$

So, based on this equivalence we know that if I compute the rank of the controllability matrix and it is of full rank, then the rank of the transpose of that observability matrix would also remain the same and the rank does not change under any transpose ok. So, we obtain the following results that the following statements are equaling the system AC-LTI is observable, rank of the observability matrix is n which is the dimension of the a matrix.

So during the controllability we have defined this as the matrix test, the third is that no eigenvector of A is in the kernel of C this is the eigen vector test and the simplification of the eigenvector test which we have defined as the PBH test that the rank of this matrix is equal to n for all lambda belonging to the set of complex numbers ok. Now there was one additional results that is the Lyapunov test for the observability which a assumes that the matrix A is at stability matrix.

So, we can say that the system is observable if and only if there is a unique positive definite solution  $W$  to this Lyapunov equation in the continuous time and this Lyapunov equation in the discrete time and moreover the unique solution to this equation is given by this one.

So, we had seen that detailed results or detailed proof of these results during the controllability week. So, the equivalence or the duality between the controllability and observability particularly for the LTI systems remains the same right. So, the proof remains the same as what we had seen earlier.

Observability Tests: LTV

Theorem (Necessary and Sufficient condition)

The pair  $(A(t), C(t))$  is observable at time  $t_0$  if and only there exists a finite  $t_1 > t_0$  such that the  $n \times n$  matrix

$$W_O(t_0, t_1) := \int_{t_0}^{t_1} \Phi(\tau, t_0)^T C(\tau)^T C(\tau) \Phi(\tau, t_0) d\tau,$$

is nonsingular.

Theorem (Sufficient condition)

Let  $A(t)$  and  $C(t)$  be  $n - 1$  times continuously differentiable. Then the  $n$ -dimensional pair  $(A(t), C(t))$  is observable at  $t_0$  if there exists a finite  $t_1 > t_0$  such that

$$\text{rank} \begin{bmatrix} N_0(t_1) \\ N_1(t_1) \\ \vdots \\ N_{n-1}(t_1) \end{bmatrix} = n$$

where

$$N_{m+1}(t) = N_m(t)A(t) + \frac{d}{dt}N_m(t) \quad m = 0, 1, \dots, n - 1$$

with

$$N_0 = C(t).$$

**Attention!**

For time-varying systems, duality is more "complicated", because the state transition matrix of the dual system must be the transpose of the state transition matrix of the original system, but this is not obtained by simply transposing  $A(t)$ .

Now talking about the LTV systems. So, the result we had seen earlier. So, this is the same result what we had seen earlier that the this WO matrix should be nonsingular either for LTI system or for the LTV system. But in the controllability week we had seen that for the time

varying system it is a bit difficult to compute this controlling the observability coming why? Because it requires the computation of the state transition matrix.

For the LTI system the state transition matrix is basically exponential, but for time varying system it is not necessary that it would be or it requires detailed computation. So, but so, this is if and only if this is if and only if because this is the necessary and sufficient condition for the observability. So, if you recall that for the for analyzing the controllability of the LTV system we take a different approach and we had defined only the sufficient condition and similarly we can define the in a similar way for the observability that like  $A$  and  $C$  be  $n-1$  times continuously differentiable.

Then the  $n$  dimensional pair  $AC$  is observable at  $t_0$  if there exists a finite  $t_1$  such that the rank of this matrix is equal to  $n$ . So, now, instead of ensuring the nonsingularity of this observability Gramian we compute the matrix  $n$  and then using those matrix  $n$  for  $0$  to  $n-1$  be computed strength and this is how you can compute the  $n$  the  $n$  matrices ok. So, this is only a sufficient condition, but not the necessary condition.

So, for time varying system duality is more complicated because the state transition matrix of the dual system must be that transpose of the state transition matrix of the original system right, but this is not obtained by simply transposing the  $A$  matrix right. So, because of this reason we cannot say that the controllability of the pair  $A(t) B(t)$  or let us say the controllability of the pair  $A(t) B(t)$  is not equivalent to the observability of  $A^T(t) B^T(t)$  right.
