Lecture - 25
State Transition Matrix (Part-I)

Now, we start with a State Transition Matrix. So, what is meant by State Transition Matrix?

(Refer Slide Time: 00:43)

State transition matrix:

Definition

It is defined as the transition of the states from the initial time $t=0$ to any time 't' or final time (tf) when the inputs are zero.

The slide includes a block diagram of a system $G(s)$ with input $1/s$ and output $1/s^2$. To the right is a graph showing a step input at $t=0$ and a corresponding output that starts at zero and increases linearly over time, reaching a value of 1 at $t=10$.

Logos for IIT Roorkee and NPTEL Online Certification Course are visible at the bottom left, and the number 2 is at the bottom right.

If you see a classical system the classical system here is a involvement of a plants say G of s we are we are applying input and we are getting a output. So, impede input is applied at t equals to 0, and we are expecting that the output as certain time interval say output say at say t equals to say 10 second. Now, this is the step input and now is a output. So, here output we have got at t equals to 10 second.

But, in case of a state space system along with this output there are states which are the important parameter in the system, that has been also traveled that is from t equals to 0 to t equals to f the state has been transferred. So, this transferring of the states we can we can say that state transition matrix.

Now, how will you define the state transition matrix? It is defined as the transition of states from initial time t naught to any time t or a final time t_f when the inputs are zero,

that is this trans state transition matrix has not concerned with the any type of input it is concerned with the some initial state that the t 0 to tf. Now, you see what are the significant, means say what are the importance of these state transition matrix.

(Refer Slide Time: 02:31)

Important points of the state-transition matrix:

- It is defined as the solution of the linear homogeneous state equation.
- It is the response due to the initial vector $x(0)$.
- It is dependent on the initial state vector and not the input.
- It is called as zero-input response since the input is zero.
- It is called as free response of the system since the response is excited by the initial conditions only.

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

The first point it is defined as the solution of linear homogeneous state equations. We have seen last time, the $\dot{X} = AX$ $x(0)$ t $e^{At}x(0)$. So, this is e^{At} is called state transition matrix and this is a homogeneous state equations.

It is response due to initial vector $x(0)$ it is response due to initial vector $x(0)$ here this is what, but if you consider a first system like this $\dot{X} = AX + BU$. So, here we will get $x(t) = e^{At}x(0) + \int_0^t e^{A(t-\tau)}B U(\tau) d\tau$ get here coefficient will get and we written d of t.

So, in this particular case this is u of t it has been taken care by $x(0)$ only whereas, if you take this part this portion that is a force portion force part in this particular part there is there is no involvement of $x(0)$. So, therefore, what we are saying here it is dependent on the initial state vector not the input. The input is concern with the force part only, this part state transition matrix is concerned with only $x(0)$. So, it is called as zero input response since input is 0, and whereas, if you take the force part this is called as zero state response. Here in this particular force part there is no initial state has been involved, but as far as now, we are discussing about the state transition matrix it is

concern with the zero input response because this portion e^{At} into X naught this portion, there is no input.

It is called as a free response of the since the response is excited by the initial condition only, that is due to initial conditions the state has been transferred and this is called state transition matrix.

(Refer Slide Time: 04:59)

Properties of the State-Transition matrix :

① — $\phi(t) = e^{At}$
 $\phi(0) = I$
 $\phi(0) = e^{A \times 0} = I$

② $\phi^{-1}(t) = \phi(-t)$

Proof: $\phi(t) = e^{At} \quad \left\{ \begin{matrix} -At \\ 0 \end{matrix} \right.$
 $\phi(t) e^{-At} = e^{At} \times e^{-At} = I$
 $\phi^{-1}(t) \phi(t) e^{-At} = \phi^{-1}(t)$
 $\frac{\phi^{-1}(t) \phi(t)}{e^{-At}} = \phi^{-1}(t) \rightarrow \text{③}$

$\phi(-t) = e^{-At} \rightarrow \text{③}$

$\phi^{-1}(t) = \phi(-t)$

4

Now, we have to see a few properties of this state transition matrix. Say $\phi(t)$ equal to e^{At} that is a state transition matrix, and now we have to pre prove this $\phi(0)$ equal to I this is a first part first property. So, how do you get I , identity matrix? So, in this particular equations, that is $\phi(0)$ we replace we will get identity matrix.

Now, the second properties, we have to prove $\phi^{-1}(t)$ equal to $\phi(-t)$ that is ϕ inverse of t equal to ϕ of minus t . Now, how will you prove this one? So, now, we start with the same equation $\phi(t)$ equal to e^{At} . Now, through this equation we now, post multiply by e^{-At} , that is what we have to do to this equation we have to multi post multiply by e^{-At} .

So, after post multiplication what we will get? We will get $\phi(t)$ to e^{-At} equal to e^{At} into e^{-At} at this is post multiplications, that is $\phi(t)$ multiplied by e^{-At} at here e^{At} multiplied by e^{-At} at we will get a anti matrix. So, now, our main purpose is to get $\phi^{-1}(t)$, equal to

phi of minus t. Now, what we will do? We will pre multiply both side by phi inverse of t. So, what we will get? So, if you multiply this phi inverse of t into phi of t to e of e raised to minus at, so phi phi inverse of t, that is I. So, this is cancelled; what we will get e raised to minus at equals to phi inverse of t.

So, e raised to minus at equals to phi inverse of t now, this if the phi of minus t equal to e raised to minus at just like phi of t equals to e raised to plus at, but if you say phi of minus t equal to e raised to minus A t. Now, if you see this equation say 1, you can say this equation 2, if you compare these equations, so what we will get? We will get phi of phi inverse t equals 2 phi of minus t, this is a second property.

(Refer Slide Time: 08:24)

$$\phi(t_2-t_1) \phi(t_1-t_0) = \phi(t_2-t_0)$$

$$= e^{A(t_2-t_1)} \times e^{A(t_1-t_0)}$$

$$= e^{A t_2 - A t_1 + A t_1 - A t_0} = e^{A(t_2-t_0)} = \phi(t_2-t_0)$$

Now, we see the another property, then another property is phi of t 2 minus t 1, phi of t 1 minus t 0 that is equal to phi of t 2 minus t 0, phi of t 2 minus t 1, phi of t 1 minus 0 equal to phi of t 2 minus t 0.

Now, this we can express through a diagram. Now, here on point this one, is a another point here. Now, here X of t 0 and now here is X of t 1. Now, the state has been transferred from X of t 0 to t 1. So, that has been represented by phi of t 1 minus t 0 then same state. Now, you see take X of t 2, t 2. Now, here also the state has been transferred form X of t 1 to X of t 2 so it has been represented by phi of t 2 minus t 1.

Now, you just see this $\phi(t_2 - t_1) \phi(t_1 - t_0)$ equals to $\phi(t_2 - t_0)$ that is this particular portion, $\phi(t_2 - t_0)$. Now, we have to prove this part mathematically. How will you prove this? So, here $\phi(t_2 - t_1) \phi(t_1 - t_0)$, now, you have to solve this. So, this is also a transition matrix state transition matrix. So, it has been represented by $e^{A(t_2 - t_1)}$ you see this portion this part.

And about this $\phi(t_1 - t_0)$ it has been written by $e^{A(t_1 - t_0)}$. Now, we solve this one. So, we can write down as $e^{A(t_2 - t_1)} e^{A(t_1 - t_0)}$ that is manipulations $e^{A(t_1 - t_0)}$ multiplied by $e^{-A(t_1 - t_0)}$. Now, you see here $e^{A(t_1 - t_0)}$, $e^{-A(t_1 - t_0)}$ this will be cancelled. So, what we will get? $e^{A(t_2 - t_0)}$ and that is nothing, but $\phi(t_2 - t_0)$. Now, we have prove this part.

So, your transition for state from t_0 to t_1 , t_1 to t_2 , but it may possible that the state at X equal to t_2 may transferred to X equals to say t_3 that means, X equal to t_3 that is it can be represented by a $\phi(t_3 - t_2)$. Now, how do you express this through state transition matrices? That is $\phi(t_3 - t_2)$, $\phi(t_2 - t_1)$, $\phi(t_1 - t_0)$, that is equal to $\phi(t_3 - t_0)$ that is you see here $\phi(t_3 - t_2)$ this one, $\phi(t_2 - t_1)$, then $\phi(t_1 - t_0)$ and this is a complete part is the involvement of $\phi(t_3 - t_0)$.

So, similarly more state elements we can add it and we can express these in terms of state transition matrix.

(Refer Slide Time: 12:48)

Handwritten derivation on a slide:

$$[\phi(t)]^m = \phi(mt) \Rightarrow \text{m +ve index}$$

$$[\phi(t)]^m = e^{At} \cdot e^{At} \cdot e^{At} \dots e^{At} \quad (\text{m times})$$

$$= e^{mA t}$$

$$= \phi(mt)$$

There is a circled $\phi(t)$ with an arrow pointing to the e^{At} terms in the derivation.

Now, the next properties say $\phi(t)$ raised to m equal to $\phi(m \cdot t)$. So, in this case m is any positive integer. Now, this we have to prove. So, now, this $\phi(t)$ raised to m . So, $\phi(t)$ is nothing, but e^{At} let us say m equals to 2 that means, e^{At} multiplied by e^{At} . Now, here m is there that means, e^{At} has been written in terms of m times. Therefore, this equation we can write down as e^{At} multiplied by e^{At} up to e^{At} .

And now up to how much terms we have to write? This we have to write m times, see here if $\phi(t)$ raised to m e^{At} m times. So, this we can write down as e^{At} m into A into t , m into A into t and now we seen that this $X(t)$ equals to $e^{At} X(0)$. So, this is written as $\phi(t)$. So, here this can be written as $\phi(m \cdot t)$ here m term has been added therefore, this results has been proved.

So, these are the properties of the state transition matrix. Sometimes when we are doing the analysis of the system and many states are involved this type of properties can be useful. Now, the point has come this e^{At} is there so that means, whenever required state transition matrix we have to calculate e^{At} . Now, how to calculate it? So, if you see the literature there are various methods are available. So, these methods are useful to calculate the state transition matrix then we see the various methods for determination of state transition matrix.

(Refer Slide Time: 15:27)

Methods for obtaining State transition matrix :

- Power Series method ✓
- Laplace transform method ✓
- Diagonalization method ✓
- Cayley-Hamilton method ✓

$$\dot{X} = A \cdot X$$

$$X(t) = e^{At} X(0)$$

$$\phi(t) = e^{At} = \mathcal{L}^{-1} \left[(sI - A)^{-1} \right]$$

8

So, first one is Power Series method, Laplace transform method, Diagonalization method and Cayley-Hamilton method. So, these 4 methods can be useful to get the state transition matrix. If you take any example then apply these 4 methods you will get the same results but now which method to be applied. So, this depends upon the type of systems. If you see the power series method we will see it, but you will find that as the order increases calculation is quite difficult and sometimes if we do not know whether we are getting the result or not. This Laplace transform method is based on the s domain and Laplace is a very important tool. Therefore, we will find that the Laplace transform method is quite useful.

We have already seen this approach earlier to get the state equation, that is $\dot{X} = AX + X(0)$ and now these $\phi(t)$ equal to e^{At} into $X(0)$ and now these $\phi(t)$ equal to e^{At} equals to Laplace inverse of $sI - A$ inverse. By means of this we can calculate this state transition matrix using Laplace transform method that is you have to take $sI - A$ inverse.

Now, the diagonalization method, this method is based on the concept of converting the given system matrix into the diagonal form and in this case there is a need to go for the modal matrix. So, if you see the calculation wise this method is quite cumbersome, but Laplace transfer is quite better.

Now, the next is Cayley-Hamilton theorem this is a very important theorem and it has wide applications. So, we will find that this method is also useful in getting the state transition matrix. Now, we will see through, but this is the method we already seen only, so method which we have to see power and diagonalization and Cayley-Hamilton theorem. Now, we start with power series method.

(Refer Slide Time: 17:40)

Power series method:

$$\dot{X} = AX \quad \dot{X}(t) = A X(t)$$

$$X(t) = e^{At} X(0) \quad \left\{ e^{At} = I + At + \frac{A^2 t^2}{2!} + \frac{A^3 t^3}{3!} + \dots \right.$$

$$X(t) = C_0 + C_1 t + C_2 t^2 + C_3 t^3 + \dots + C_k t^k$$

$$\dot{X}(t) = A X(t)$$

$$\underline{\quad} =$$

$$C_1 + 2 C_2 t + 3 C_3 t^2 + \dots = A (C_0 + C_1 t + C_2 t^2 + C_3 t^3 + \dots)$$

Comparing the coefficients of t^n

$$\begin{aligned} C_1 &= A C_0 \\ C_2 &= A C_1 \quad ; \quad C_2 = \frac{A}{2} C_1 \quad ; \quad C_2 = \frac{A}{2} + A C_0 = \frac{A^2}{2!} C_0 \end{aligned}$$

IIT ROORKEE | NPTEL ONLINE CERTIFICATION COURSE | 9

Now, we start with power series method. So, here we start with \dot{X} equal to AX or this we can write down as $\dot{X} = AX$. And here $X(t)$ state equation equal to $e^{At} X(0)$ and here this e^{At} that is equal to $I + At + \frac{A^2 t^2}{2!} + \frac{A^3 t^3}{3!} + \dots$. Now, we have to prove this. Why? The state transition matrix e^{At} equals to this way.

Now, we start doing it. So, first of all what we will do we will assume that say $X(t) = C_0 + C_1 t + C_2 t^2 + \dots + C_k t^k$. Now, we are concerned with the \dot{X} . So, here $\dot{X} = AX$, now if you see \dot{X} so now, differentiate these equations. So, if you differentiate \dot{X} this term of C_0 will not present. So, terms of C_1 C_2 up to C_k will be present therefore, we write the equation as this is $C_1 + 2 C_2 t + 3 C_3 t^2 + \dots = A (C_0 + C_1 t + C_2 t^2 + C_3 t^3 + \dots)$.

So, here $3 C_3 t^2$ means $3 C_3 t^2$ into t^2 equal to A into $X(t)$. So, we can write down as $A C_0 + A C_1 t + A C_2 t^2 + \dots$ like this or we can write $3 C_3 t^2$. So, these terms we have got and now our main purpose is to get this result. So, what we can do? Means in what way we impose. So, we can see that we can compare the various terms of t and somewhere we can achieve the result.

So, please see it. So, now, what we will do comparing the coefficients of t . Now, you compare the coefficient of t . So, now, see here, for if see that the term t raised to 0. So,

you will find that t raised to 0 means 1. So, here for this it is C_1 and here is A into C naught. Similarly we compare that terms t raised to 1. So, here that is t . So, we can write down as see here t raised to 1, $2 C_2$, so $2 C_2$. Now, here we find A into C_1 into t 's. Just see here $A C_1$ into t , so we can write down as A into C_1 . So, from this we can write down as C_2 equal to A by 2 into C_1 C_2 equals to A by 2 into C_1 . But we know C_1 ; what is C_1 ? The C_1 is A into C naught. So, we replace the value of C_1 in this equation. So, we will get C_2 equal to A by 2 into A into C naught equal to A square by 2. So, we can write down as a factorial 2 into C naught.

So, why are your factorial, we will see later on. Now, here we have compare the coefficient of t^1 . Now, similarly we have to compare the coefficient of t^2 .

(Refer Slide Time: 22:37)

t^2 ; $3 C_3 = A C_2$; $3 C_3 = A \times \frac{A^2}{2} C_0$; $C_3 = \frac{1}{6} A^3 C_0$
 $= \frac{1}{3!} A^3 C_0$

Recall $t \Rightarrow$
 $x(t) = C_0 + C_1 t + C_2 t^2 + \dots + C_k t^k$
 $x(t) = C_0$
 $x(t) = C_0 + C_1 t + C_2 t^2 + \dots + C_k t^k$
 $= C_0 + A C_0 t + \frac{A^2}{2!} C_0 t^2 + \dots + \frac{1}{k!} A^k t^k C_0$
 $= C_0 \left[I + A t + \frac{A^2}{2!} t^2 + \frac{A^3}{3!} t^3 + \dots + \frac{1}{k!} A^k t^k \right]$
 $x(t) = e^{At} C_0$

So, if you compare the coefficient of t^2 we will get $3 C_3$ into A into C_2 , so here $3 C_3$ into A . Now, $3 C_3$ into a what is C_2 ? C_2 we are already got A square factorial 2 into C naught. So, we replace these values here. So, you will can write A square by 2 into C naught.

Now, we have got A square by 2 C naught, but you know if we know also C naught. So, C naught is, so you will find that that C naught is no value. So, we can keep like this only. So, we can write down as this C_3 equal to 3 we will take this side and we will get a A cube into C naught, so here we can write down this as 6 into A^3 into C naught and if you write this as this as a factorial 3 that is 3 into 2, 6 A cube into C naught.

Now, similarly we have to push it further. Suppose if you replace, if you replace t equals to 0 in equation of X of t that is X of t equals to $C_0 + C_1 t + C_2 t^2 + \dots + C_k t^k$. So, you will get X of 0 equal to C_0 . So, now, we have got the value of X naught C_0 , C_1 , C_2 , C_3 assume that we got up to C_k . Now, we replace all this element in the given equations and now we will see what results we will get that is X of t equal to $C_0 + C_1 t + C_2 t^2 + \dots + C_k t^k$.

So, we have got all values of $C_0, C_1, C_2, \dots, C_k$ into t^k . So, you can also find this process A equals $C_0 + C_1 t + C_2 t^2 + \dots + C_k t^k$ this portion and we have got all values and now we try to replace. So, if you replace it C_0 , what is the value of C_1 ? C_1 you will find you get C_1 equals to A into C_0 , C_2 equals to A square factorial into C_0 and C_3 equal to 1 by factorial 3 A cube into C_0 .

So, we replace these values and we will find C_0 into A into C_0 into t plus C_2 A square factorial 2 , C_0 into t square plus A cube factorial 3 C_0 into t cube and this process repeated and we will find that this is 3 our terms are up to k . So, we have 1 by a factorial k into A raised to 3 . So, k , so we A raised to k into t raised to k .

Now, we will find that in all these cases in all these cases the term C_0 is common. So, we will take C_0 . So, we can write down 1 plus A into t A square factorial 2 into t square, A cube factorial 3 into t cube plus 1 by factorial k A raised to k into t^k . So now, we have got this one. Now, what is the X of t ? So, X of t is equal to e raised to $A t$ into X naught. And what is a X naught? This X naught we are already calculated as C_0 and therefore, this is e raised to $A t$ into C_0 and therefore, if you compare this equation this is the same equation.

(Refer Slide Time: 27:14)

$$e^{At} = I + At + \frac{A^2 t^2}{2!} + \frac{A^3 t^3}{3!} + \dots + \frac{A^k t^k}{k!}$$

Now, here e raised to A t is nothing but this part that means, we can write down e raised to A t equal to I plus A into t plus A square t square factorial 2 plus A cube t cube factorial 3 and like this A k t k factorial k. Now, this is the direct formula. So, by means of this formula we can easily get the state transition matrix.

So, in that case what is the input is available to you input is available to is A, A matrix. So, you replace the A matrix and solve it we can get the result.

(Refer Slide Time: 28:06)

Example

$$[A] = \begin{bmatrix} -2 & 1 \\ 0 & -2 \end{bmatrix}$$

$$e^{At} = I + At + \frac{A^2 t^2}{2!} + \dots$$

$$A = \begin{bmatrix} -2 & 1 \\ 0 & -2 \end{bmatrix} ; A^2 = \begin{bmatrix} -2 & 1 \\ 0 & -2 \end{bmatrix} \begin{bmatrix} -2 & 1 \\ 0 & -2 \end{bmatrix} = \begin{bmatrix} 4 & -4 \\ 0 & 4 \end{bmatrix}$$

$$A^3 = A \cdot A^2 = \begin{bmatrix} \quad & \quad \\ \quad & \quad \end{bmatrix}$$

$$e^{At} = \begin{bmatrix} e^{-2t} & t e^{-2t} \\ 0 & e^{-2t} \end{bmatrix}$$

Now, we try to solve one example. Suppose if you are taking a matrix equal to minus 2, 1, 0, minus 2. And we want to determine we have to determine the state transition matrix e^{At} by means of power series approach. So, here e^{At} equal to same formula we write is $I + At + \frac{A^2 t^2}{2!} + \frac{A^3 t^3}{3!} + \dots$ and like this.

Now, here you find that we will get A , A^2 , A^3 it means that we have to calculate a many multiplications, multiple multiplication has to be solved and we will find out do this calc to do these calculations or to carry out this calculation sometimes it is quite cumbersome.

Just we see here suppose if you take A is like this same thing minus 2, 1, 0, minus 2. Now, we have to determine A^2 , so A^2 is minus 2 1 0 minus 2 here minus 2 1 0 minus 2 and if you solve this one you will get 4 minus 4 0 into 4 and we have got A^2 , similarly you can get A^3 A^3 equals to A into A^2 .

So, we have to solve you get some values and finally, you have to replace in these particular equations. So, you will find that there are some terms. So, everywhere these terms are added and finally, if you get e^{At} as $e^{-2t} (t^0 + t + \frac{t^2}{2} + \frac{t^3}{6} + \dots)$. That means what you do? You have to determine A^2 , A^3 , A^4 like this they replace these values.

(Refer Slide Time: 30:24)

The image shows a handwritten mathematical formula on a whiteboard background. The formula is:

$$e^{-2t} = 1 + (-2t) + \frac{1}{2!} (-2t)^2 + \frac{1}{3!} (-2t)^3 + \dots$$

Below the formula, there is a horizontal line. Underneath the line, there are two circled numbers: a circled 2 and a circled 3. Arrows point from these circled numbers to the denominators 2! and 3! in the formula above.

At the bottom of the slide, there is a dark blue footer bar containing the logos for IIT ROORKEE and NPTEL ONLINE CERTIFICATION COURSE, along with the page number 14.

And from this same expression taking different elements we will get e raised to minus $2t$, that is e raised to minus $2t$ portion is nothing but $1 + \text{minus } 2t + \frac{1}{2!} \text{ plus } \frac{1}{3!} \text{ minus } 2t^2 + \frac{1}{4!} \text{ plus } \frac{1}{5!} \text{ minus } 2t^3 + \dots$. This is e raised to minus $2t$. Similarly we will get $t e$ raised to minus $2t$, $t^2 e$ raised to minus $2t$, $t^3 e$ raised to minus $2t$. So, this is very simple calculations you can easily do it.

But here the main intention of this example is that sometimes it may not possible that you can get a similar type of results that is instead of minus 2 sometimes we get 4, it may get 7. In that case to make these elements or make adjust this element by means of power series expansion is quite difficult. Therefore, as we increase the order we will not recommend this method to get the state transition matrix because calculation is quite difficult. That means, in that is case it is better to go for the Laplace transform approach or there are other approaches that is called Cayley-Hamilton theorem or diagonalization that also helpful, but this approach sometimes is quite difficult.

(Refer Slide Time: 31:45)

Now, you see the references Gopal, D Roy Choudhury, Kuo, Varmah and so these references can you can use or if try to solve many example as possible, using this power series expansions and as I told you that you identifying the various cases where this method fails. And the same problem you can solve by a Laplace transform approach and you prove that a Laplace transform is better than the power series method.

Thank you.
