Decision Support Systems for Operations Management (Contd.)

Hi, welcome to our 4th module on ‘Decision Support Systems for Operations Management’!

(Refer Slide Time: 00:28)

Today, we are going to deliberate upon a very simple topic but widely deployed and useful for industry people and that is determination of product mix.

(Refer Slide Time: 00:37)

Introduction

- ❑ Product Mix is the combination of different products offered by a company for sale to the consumer.
- ❑ Not all products manufactured by a company are alike.
- ❑ One product may differ from another in its sale price, its production cost, and its attractiveness to the consumer.
- ❑ Hence, a company might find that it is more profitable to devote more of its resources to selling one product over another.

NPTEL Online Certification
IIT Kharagpur

The slide features a background with various icons including gears, a tree, a chemical structure, and a hard hat. A speaker is visible in the bottom right corner of the slide frame.

Now, what is product mix? Product mix is the combination of different products offered by a company for sale to the consumer. Now, not all products manufactured by a company are alike. One product may differ from another in its sale price, its production cost and its attractiveness to the consumer. Hence, a company might find that it is more profitable to devote more of its resources to selling one product over another.

(Refer Slide Time: 01:30)

Introduction

- ❑ The challenge for the company is to maximize its contribution or minimize its costs subject to various constraints like
 - ✓ availability of raw material,
 - ✓ Availability of labor, and other resources
 - ✓ while satisfying the demands from the consumers.

NPTEL Online Certification
IIT Kharagpur

The slide features a background with various icons including gears, a tree, a chemical structure, and a hard hat. A speaker is visible in the bottom right corner of the slide frame.

Therefore, the challenge for the operations manager, the marketing managers and the finance managers for a company is to maximize, its contribution or minimize its costs subject to

various constraints like; availability of raw material, availability of labor and other resources, while satisfying the demands from the consumers.

(Refer Slide Time: 02:14)

Introduction

- These type of problems can best be solved by incorporating a standard linear programming model in a decision support system and then perform sensitivity analysis.

NPTEL Online Certification
IIT Kharagpur

This type of problems can best be solved by incorporating a standard linear programming model in a decision support system and then perform sensitivity analysis.

(Refer Slide Time: 02:41)

Introduction

- Sensitivity analysis attempts to assess the impact of a change in the input data or parameters on the proposed solution.
- Sensitivity analysis is extremely important in DSS because it allows
✓ flexibility and adaptation to changing conditions and to the requirements of different decision-making situations.

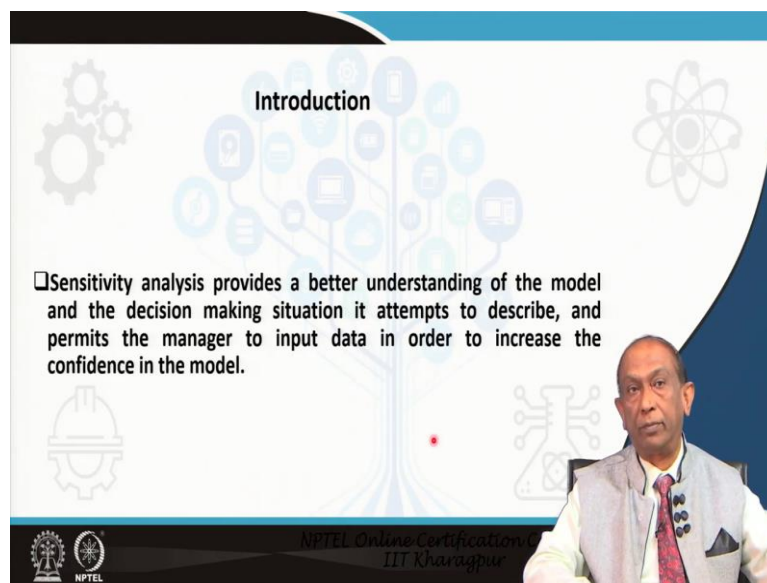

NPTEL Online Certification
IIT Kharagpur

Now, what is the sensitivity analysis? Sensitivity analysis attempts to find out the effect of a change in the input data or parameters on the proposed solution. That means, if the managers, they change the values of say 1 input parameter, what will be the effect on say revenue, or

price, or cost, depending on whether the problem is of the type maximization or minimization.

Sensitivity analysis is extremely important in decision support system; because it allows flexibility and adaptation to changing conditions and to the requirements of different decision making situations.

(Refer Slide Time: 04:19)

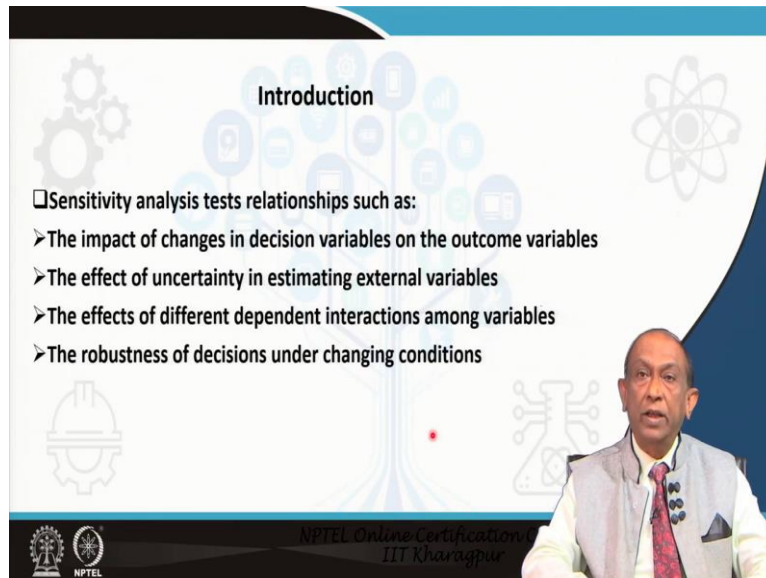

Introduction

- Sensitivity analysis provides a better understanding of the model and the decision making situation it attempts to describe, and permits the manager to input data in order to increase the confidence in the model.

NPTEL Online Certification
IIT Kharagpur

Sensitivity analysis therefore, provides a better understanding of the model and the decision making situation, and thereby it permits the manager to input data in a way that might increase his confidence in using that model.

(Refer Slide Time: 05:00)

Introduction

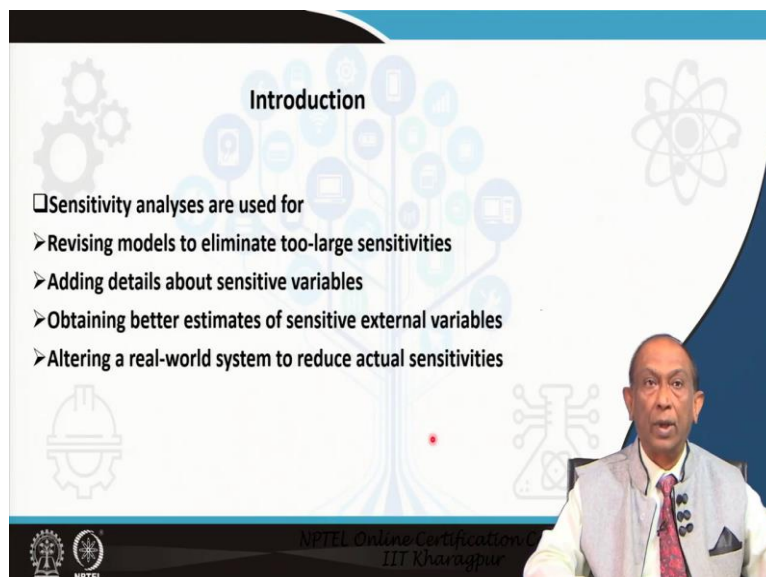

□ Sensitivity analysis tests relationships such as:

- The impact of changes in decision variables on the outcome variables
- The effect of uncertainty in estimating external variables
- The effects of different dependent interactions among variables
- The robustness of decisions under changing conditions

NPTEL Online Certification
IIT Kharagpur

Sensitivity analysis tests relationships such as, the impact of changes in decision variables on the outcome variables. It also allows us to test the effect of uncertainty in estimating external variables. Sensitivity analysis also helps us to find out the effect of different dependent interactions among the variables; and thereby also find out the robustness of the decisions under changing conditions.

(Refer Slide Time: 06:16)

Introduction

□ Sensitivity analyses are used for

- Revising models to eliminate too-large sensitivities
- Adding details about sensitive variables
- Obtaining better estimates of sensitive external variables
- Altering a real-world system to reduce actual sensitivities

NPTEL Online Certification
IIT Kharagpur

Sensitivity analysis are used for revising models to eliminate too large sensitivities. This model is used for adding details about sensitive variables. This technique also helps the

managers to obtain better estimates of sensitive external variables and also to alter a real world system to reduce the actual sensitivities.

(Refer Slide Time: 07:14)

Introduction

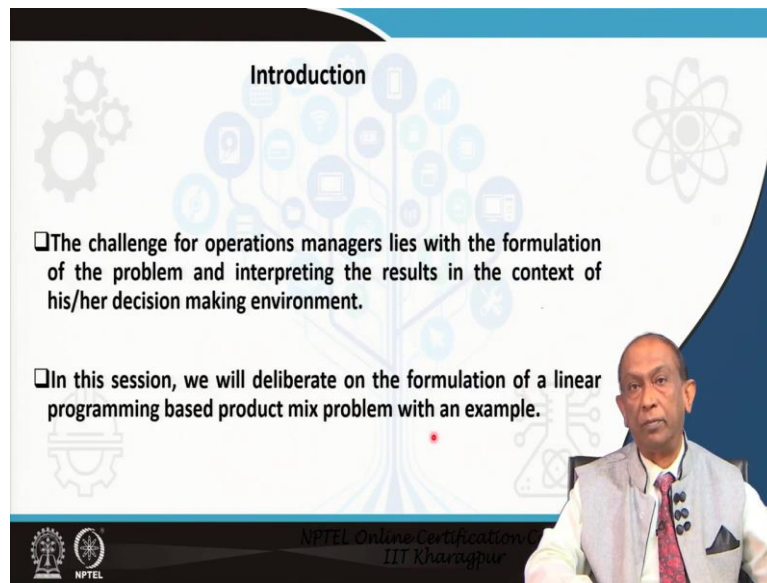

- Both the solution to LP problems and the associated sensitivity analysis may easily be obtained using EXCEL SOLVER or GOAL SEEK feature for 'What-if' Analysis.
- Similar solution macros may also be coded and embedded in any DSS

NPTEL Online Certification
IIT Kharagpur

Both the solution to the linear programming problems and the associated sensitivity analysis may easily be obtained using EXCEL SOLVER or the GOAL SEEK feature of excel to do 'What-if' kind of analysis.

What will happen to the output variable? If, one of the input variable is changed by some amount. This kind of analysis you are very familiar with excel is now very commonly deployed software and it has a goal seek feature, which allows you to find out answers to this kind of problems. Similar solution macros may also be coded and embedded in any Decision Support System.

(Refer Slide Time: 08:44)

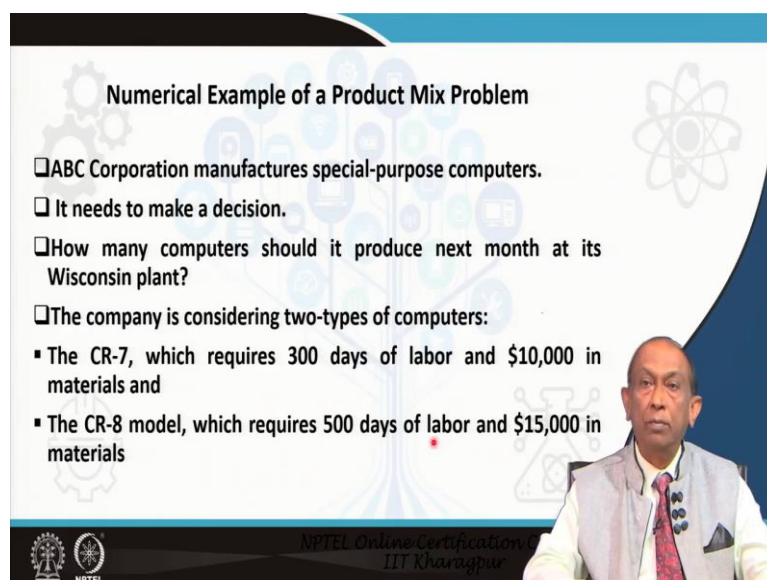

Introduction

- ❑ The challenge for operations managers lies with the formulation of the problem and interpreting the results in the context of his/her decision making environment.
- ❑ In this session, we will deliberate on the formulation of a linear programming based product mix problem with an example.

NPTEL Online Certification
IIT Kharagpur

The challenge for operations managers therefore, lie with the formulation of the problem and interpret the results in the context of his or her decision making environment. In this session, we will deliberate on the formulation of a linear programming based product mix problem with an example. What is the problem? ABC Corporation manufactures special-purpose computers.

(Refer Slide Time: 09:32)

Numerical Example of a Product Mix Problem

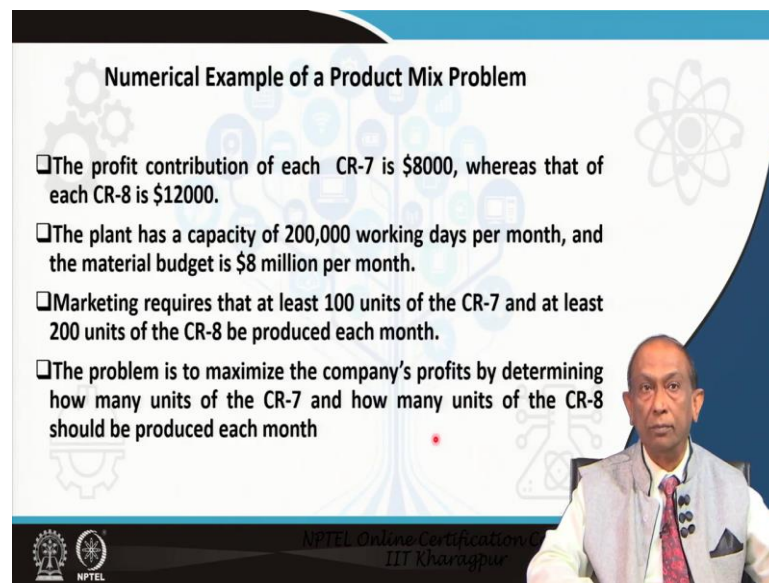

- ❑ ABC Corporation manufactures special-purpose computers.
- ❑ It needs to make a decision.
- ❑ How many computers should it produce next month at its Wisconsin plant?
- ❑ The company is considering two-types of computers:
 - The CR-7, which requires 300 days of labor and \$10,000 in materials and
 - The CR-8 model, which requires 500 days of labor and \$15,000 in materials

NPTEL Online Certification
IIT Kharagpur

Now, the operations managers of that company, they have to take a decision and their plant is based in Wisconsin in US. The first question is how many computers should the company

produce next month at it is Wisconsin plant? The company is considering two types of computers. The first model which is designated as CR-7 requires 300 days of labor and 10,000 dollars in materials. And, the second model that is CR-8 requires 500 days of labor and 15,000 dollars, worth of materials.

(Refer Slide Time: 11:19)

Numerical Example of a Product Mix Problem

- ❑ The profit contribution of each CR-7 is \$8000, whereas that of each CR-8 is \$12000.
- ❑ The plant has a capacity of 200,000 working days per month, and the material budget is \$8 million per month.
- ❑ Marketing requires that at least 100 units of the CR-7 and at least 200 units of the CR-8 be produced each month.
- ❑ The problem is to maximize the company's profits by determining how many units of the CR-7 and how many units of the CR-8 should be produced each month

NPTEL Online Certification
IIT Kharagpur

The profit contribution of each CR-7 model is dollar 8000, whereas, the contribution of 1 unit of CR-8 is 12,000 dollars. The plant has a capacity of 200,000 working days per month, and the material budget that is available to the managers is dollar 8 million per month.

The marketing managers have informed that they require at least 100 units of the CR-7 and at least 200 units of the model CR-8 to be produced each month. Now, the problem is to maximize the company's profits by determining how many units of CR-7 and how many units of the model CR-8 be produced each month.

(Refer Slide Time: 13:34)

Numerical Example of a Product Mix Problem

- In a real-world application, it could possibly take months to obtain the data in the problem statement.
- While collecting such data, the manager may uncover other facts about how the model can be structured so that it can be easily solved.

NPTEL Online Certification
IIT Kharagpur

So, that is the given problem. In a real-world application, it could possibly take months to obtain the data that is stated in this problem. And, while collecting such data, the concerned managers may uncover other facts about how the model can be structured. So, that it can be easily solved.

(Refer Slide Time: 14:24)

Numerical Example of a Product Mix Problem

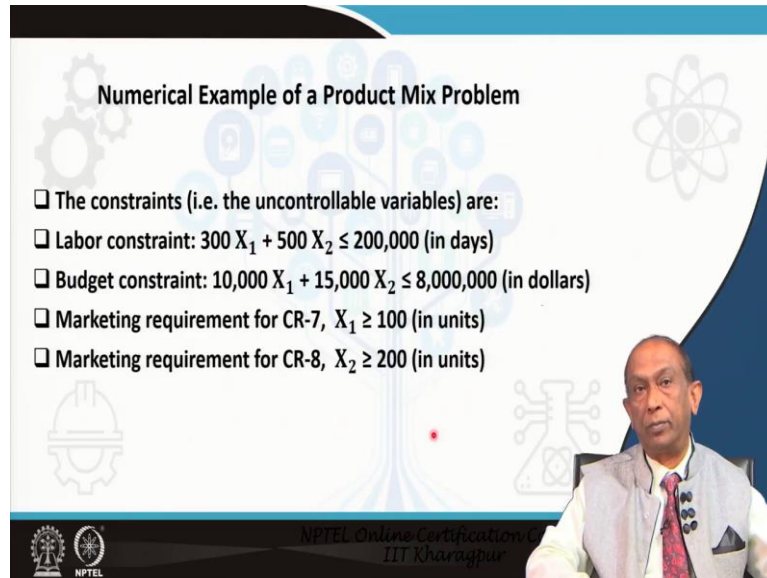

- The decision variables in this problem are:
 - X_1 = units of CR-7 to be produced
 - X_2 = units of CR-8 to be produced
- The result variable is:
 - Total profit = Z
- The objective is to maximize total profit:
 - $Z = 8000 X_1 + 12000 X_2$

NPTEL Online Certification
IIT Kharagpur

So, now let us get into the formulation of the problem, which is extremely simple, the decision variables related to this problem are say, X_1 representing the units of the model CR-7 to be produced and X_2 is the number of units of CR-8 model to be produced. So, the result

variable in this problem is the total profit, which is designated by Z . The objective is to maximize total profit. Therefore, the profit equation Z or contribution rather, total contribution Z equal to $8000 X_1$ plus $12000 X_2$.

(Refer Slide Time: 15:57)

Numerical Example of a Product Mix Problem

- ❑ The constraints (i.e. the uncontrollable variables) are:
- ❑ Labor constraint: $300 X_1 + 500 X_2 \leq 200,000$ (in days)
- ❑ Budget constraint: $10,000 X_1 + 15,000 X_2 \leq 8,000,000$ (in dollars)
- ❑ Marketing requirement for CR-7, $X_1 \geq 100$ (in units)
- ❑ Marketing requirement for CR-8, $X_2 \geq 200$ (in units)

NPTEL Online Certification
IIT Kharagpur

The constraints for this problem are number 1 labor constraint that can be written in terms of $300 X_1$ plus $500 X_2$, less than equal to 200 000 in terms of days. So, this is given in the problem. The budget constraint similarly can be written as $10,000 X_1$ plus $15,000 X_2$, less than equal to 8 million dollars.

Marketing requirement for the model CR-7 is expressed in terms of X_1 being greater than equal to 100 numbers and marketing requirement for the model CR-8 can be expressed, in terms of X_2 being greater than equal to 200 numbers.

(Refer Slide Time: 17:28)

Numerical Example of a Product Mix Problem

- The labor and budget constraints may each have some slack in them when the left-hand side is strictly less than the right-hand side.
- This slack will indicate excess resources available.

NPTEL Online Certification Course
IIT Kharagpur

Now, you see the labor and the budget constraints each one of them may have some slack in them when the left-hand side is strictly less than the right-hand side. Because, if you look at the problem structure you see $300 X 1$ plus $500 X 2$ is strictly less than equal to 200 1,000; that means, $300 X 1$ plus $500 X 2$ plus some slack variable say $S 1$ will make it equal to 200 100 1000, that $S 1$ is the slack variable.

Similarly, for this $10,000 X 1$ plus $15,000 X 2$ plus something $S 2$ is the slack variable associated with this constraint that becomes equal to 8 million dollars. So, that means, if the constraint is of the type strictly less than, then you can associate a slack variable with that and this slack will indicate the excess resources that are available.

(Refer Slide Time: 19:20)

Numerical Example of a Product Mix Problem

- ❑ The marketing requirement constraints may each have some surplus in them when the left hand side is strictly greater than the right hand side.
- ❑ These surplus variables indicate that there is some room to adjust the right hand sides of these constraints.

NPTEL Online Certification
IIT Kharagpur

On the other hand the marketing requirement constraints may each have some surplus in them, whereby the left hand side is strictly greater than the right hand side. That means, you see here X_1 is strictly greater than equal to this; that means, X_1 minus something say S_3 equals 100. Similarly, X_2 minus S_4 equal to 200. So, this S_3 and S_4 in this context are known as surplus variables.

These surplus variables indicate that there is some room to adjust the right hand side values of this constraints; that means, the marketing requirements can be adjusted accordingly.

(Refer Slide Time: 20:44)

Numerical Example of a Product Mix Problem

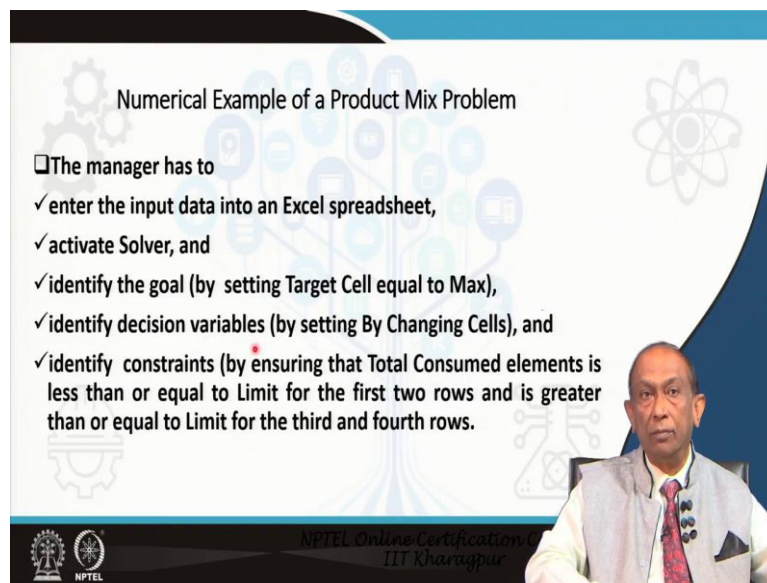

- ❑ These slack and surplus variables are of great value to a decision maker because LP solution methods use them in establishing sensitivity parameters for economic 'what-if' analyses.
- ❑ Excel comes with an add-in Solver to obtain an optimal solution for maximizing profit.

NPTEL Online Certification
IIT Kharagpur

These slack and surplus variables are of great value to a decision maker, because Linear Programming solution methods use them in establishing sensitivity parameters for economic ‘what-if’ analysis.

Excel comes in with an add-in and that is the solver to obtain an optimal solution for maximizing profit or minimization of cost, basically solver add in basically helps you to solve various types of optimization problems.

(Refer Slide Time: 21:57)

Numerical Example of a Product Mix Problem

- ❑ The manager has to
 - ✓ enter the input data into an Excel spreadsheet,
 - ✓ activate Solver, and
 - ✓ identify the goal (by setting Target Cell equal to Max),
 - ✓ identify decision variables (by setting By Changing Cells), and
 - ✓ identify constraints (by ensuring that Total Consumed elements is less than or equal to Limit for the first two rows and is greater than or equal to Limit for the third and fourth rows).

NPTEL Online Certification
IIT Kharagpur

And, when you get the add-in that is the solver, the manager has to enter the input data in an excel spreadsheet. Activate the solver, identify the goal by setting the target Cell equal to Max. The manager has to identify decision variables by setting By Changing Cells and identify constraints by ensuring that total consumed elements is less than or equal to the limit for the first two rows and is greater than or equal to limit for the third and fourth rows.

(Refer Slide Time: 23:24)

Numerical Example of a Product Mix Problem

- ❑ Also, in Options, the manager needs to activate the boxes –
 - ✓ Assume Linear Model and
 - ✓ Assume Non-negative, and then
 - ✓ Solve the problem.

NPTEL Online Certification Course
IIT Kharagpur

We will basically show you, how the data has been entered, also after entering the data the manager needs to activate two boxes, wherein they have to basically tick, against the first one is assumption of a linear model and also they have to tick the non-negativity restriction and then solve the problem.

(Refer Slide Time: 24:01)

Numerical Example of a Product Mix Problem

- ❑ Next, the manager, needs to select all the three reports– Answer, Sensitivity, and Limits – to obtain an optimal solution of
- ❑ $X_1 = 333.33$, $X_2 = 200$, and Profit = \$5,066,667.
- ❑ The evaluation of the alternatives and the final choice depend on the type of criteria selected.
- ❑ Are we trying to find the best solution? Or, will a good-enough result be sufficient?

NPTEL Online Certification Course
IIT Kharagpur

And, thereafter the manager needs to select all the three reports, that are generated by the solver and the three reports are the answer sensitivity and the limits. And, in this case the

optimal solution comprises of X 1 equal to 333.33, X 2 equals 200, and profit is given all of you can try this problem in the solver and see whether you get this result or not.

Instead of the linear model, if you opt for an integer solution, then you will get an integer output corresponding to X 1. The evaluation of the alternatives and the final choice will depend on the type of criteria selected; that means, it will depend upon what the manager wants.

Are we trying to find out the best solution? Or, will an effective solution a good-enough result will be sufficient? That will depend upon what the operations group, they feel like or they want.

(Refer Slide Time: 26:04)

	X1	X2	Total	Capacity
Decision Variables	333.333	200		
Contribution	8000	12000	5066667	
Labor Constraint		300 500	200000	200,000
Budget Constraint		10000 15000	6333333	8,000,000
Marketing Requirement for CR-7				100
Marketing Requirement for CR-8				200

So, you see in your excel output initially to start with you have to basically supply the input values, for the labor constraint, that is 300 500 for against X 2 and the available capacity is mentioned in this cell, the budget constraints are written in this cell available is 8 million dollars. So, the constraints are entered the marketing requirements also need to be entered and the coefficient of the variable X 1 and X 2 in the objective function are entered in here.

Initially, you will supply some values to X 1 and X 2 and against those values of X 1 and X 2, this particular cell will give you, the total profit that will get generated against those X 1 and X 2 values. And, this cell in these two columns will give you the actual amount of resources that have been used.

Since, this particular excel spreadsheet is related to the optimum solution, we can see that the optimum profit value is this much, the corresponding optimal values of X 1 and X 2s are given as 333.333 and X 2 equal to 200. And, under the optimal condition, this much amount of resources related to the labor constraint has been utilized.

That means, whatever is available at the capacity, the entire available capacity with respect to the labor has been utilized. With respect to budget, what we find that even though the allocated budget or the available budget is 8 million dollars, we have utilized something like 6.33 million dollars. So, we have not able to utilize the full amount of budget; ok.

(Refer Slide Time: 29:34)

Microsoft Excel 15.0 Answer Report
 Worksheet: [Product-Mix.xlsx]Problem-Stmt
 Report Created: 9/11/2020 8:28:18 AM
 Result: Solver found a solution. All Constraints and optimality conditions are satisfied.
 Solver Engine
 Engine: Simplex LP
 Solution Time: 0.016 Seconds.
 Iterations: 2 Subproblems: 0
 Solver Options
 Max Time Unlimited, Iterations Unlimited, Precision 0.000001
 Max Sub problems Unlimited, Max Integer Sols Unlimited, Integer Tolerance 1%, Assume Nonnegative

Objective Cell (Max)				
Cell	Name	Original Value	Final Value	
\$F\$5	Contribution Total	4200000	5066666.667	

Variable Cells				
Cell	Name	Original Value	Final Value	Integer
\$D\$4	Decision Variables	300	333.3333333	Contin
\$E\$4	Decision Variables	150	200	Contin

NPTEL Online Certification Center
 IIT Kharagpur

Now, when you look into the excel output, it will come into this particular format. This is the optimal value and I started with some initial solution corresponding to that, that value was this much with iterations successive iterations total iterations have been 2. So, with successive iterations by changing the cells, the final optimal value is this much.

And, the optimal values of the decision variables X 1 and X 2 are given here. We had started the solution by giving X 1 equal to 300, X 2 equal to this much corresponding to that we got a total profit value of this much, but in the optimal solution we are getting this final values.

(Refer Slide Time: 30:46)

Microsoft Excel 15.0 Sensitivity Report

Worksheet: [Product-Mix.xlsx]Problem-Stmt
Report Created: 9/11/2020 8:28:18 AM

Variable Cells

Cell	Name	Final Value	Reduced Cost	Objective Coefficient	Allowable Increase	Allowable Decrease
\$D\$4	Decision Variables	333.3333333	0	8000	1E+30	800
\$E\$4	Decision Variables	200	-1333.333333	12000	1333.333333	1E+30

Constraints

Cell	Name	Final Value	Shadow Price	Constraint R.H. Side	Allowable Increase	Allowable Decrease
\$F\$8	Labor Constraint Total	200000	26.66666667	200000	50000	70000
\$F\$9	Budget Constraint Total	6333333.333	0	8000000	1E+30	1666666.667

NPTEL Online Certification Center
IIT Kharagpur

Next the important portion is the sensitivity analysis report. You see in this sensitivity analysis report also, you get the final values of the decision variables and then in this constraints related area corresponding to the labor constraints you get a shadow price of 26 point something.

What is the implication of this shadow price? What is the meaning of this shadow price? The shadow price basically means, you see the available or the constraint value on the right hand side of the labor constraint is this much. You see, if you increase the available resource related to this particular constraint by 1 unit, your total profit will go up by this much the shadow price.

So, shadow price basically means that, if you increase 1 unit of the available resource, then the impact on the objective function in terms of increased profit is by the amount 26.66. If, you increase this value by 2 more units, then the profit will go up by 26.666 multiplied by 2. You need not again have to run the model to get this answer, but this is valid within a range; that means, to what extent you can increase the value of this right hand side, allowable increase is this much.

So; that means, you can go up to this value plus this 50,000. If, you do that the corresponding profit will go by this shadow price multiplied by the amount by which you have increased this right hand side values. Allowable decrease similarly, if you decrease then the by for 1

unit decrease in the value of right hand side, the profit will go down by the amount that is stated in the shadow price.

That means, you can use this particular relationship without running the problem within a range of this, this is the implication of this allowable increase and this allowable decrease values. See this budget constraint the shadow price is 0 means, what?

If, you increase the available budget it will not have any effect on the total profit and as such you have already seen, that we have not been able to utilize the full budget. Let us look at this reduced cost column in this sensitivity report. Now, the reduced cost corresponding to the first decision variable that was X 1 is 0.

What does it imply; reduced cost 0 means: that now even if you start another one more unit of production for the variable X 1, it will not add to the profit. And, the objective coefficient, the coefficient of the variable X 1 in the objective function is 8000. This allowable increase and allowable decrease basically specify a range, over which the current optimal condition still holds good; ok.

If, the objective coefficient or the coefficient, of the variable X 1 in the objective function is changed within this range, the current optimality condition will not be violated. The reduced cost value corresponding to the variable X 2 is minus negative minus 1333.333 something.

What is the implication of this negative value here? Basically, it means that, if we increase the production of the variable X 2 by 1 more unit, the objective function will be reduced by this amount; that means, we will incur a loss. And, hence production of additional unit of X 2 is not recommended.

So, from the reduced cost, we can also find out that to what extent? See, in this case both the variables have appeared in the objective function. In case some variable would not have appeared in the objective function. This reduced cost column would have given us the idea that, what should be the objective coefficient for that variable and to what extent it can be manipulated such that, that variable can enter the objective function.

(Refer Slide Time: 38:32)

Numerical Example of a Product Mix Problem

- ❑ LP models can be specified directly in a number of user-friendly modeling systems.
- ❑ Cplex, Lingo and Lingo packages are very popular.
- ❑ The use of mathematical programming, especially of LP, are fairly common in practice.
- ❑ There are standard computer programs available.
- ❑ Optimization functions are available in many DSS integrated tools, such as Excel.

NPTEL Online Certification Center
IIT Kharagpur

So, LP models can be specified directly in a number of user friendly modeling systems: CPLEX, LINDO, and LINGO packages are very popular. The use of mathematical programming, especially of LP, are fairly common in practice.
