**Wave Equation in One Space Dimension**  
**D'Alembert formulae**

Now welcome to this lecture from this lecture onwards we start solving wave equations. In today's lecture we solve wave equation in 1 space dimension here we are going to consider only homogenous wave equation for the reasons that we explain in lecture 4.1 the solution is known as d'Alembert formulae.

**(Refer Slide Time: 00:43)**

The outline is at we introduce the Cauchy problem for 1 dimensional wave equation and then we look at the Canonical form for the 1 dimensional wave equation using that we obtain a solution which is known as d'Alembert formula for the solution of Cauchy problem.

**(Refer Slide Time: 01:02)**

# Cauchy problem for one dimensional wave equation

## Plan of action to solve it

So; Cauchy problem for 1 dimensional wave equation and plan of action to solve it.

(Refer Slide Time: 01:07)

### Cauchy problem for one dimensional wave equation

Given  $\varphi \in C^2(\mathbb{R})$ ,  $\psi \in C^1(\mathbb{R})$ , Solve

$$u_{tt} = c^2 u_{xx}, \quad x \in \mathbb{R}, t > 0, \quad (\text{WE-1d})$$

$$u(x, 0) = \varphi(x), \quad x \in \mathbb{R}, \quad (\text{IC-1})$$

$$u_t(x, 0) = \psi(x), \quad x \in \mathbb{R}. \quad (\text{IC-2})$$

We highlight the key points so the Cauchy points is this given functions phi in  $C^2$  of  $\mathbb{R}$  that is twice continuously differentiable and psi which is  $C^1$  of  $\mathbb{R}$  1 times continuous differentiable on  $\mathbb{R}$ . We need to solve this problem second equation we write WE wave equation 1d with 1 space dimension. So equation is  $u_{tt} = c^2 u_{xx}$  we are interested in solving  $x$  in  $\mathbb{R}$  and  $t$  positive. We could also solve for  $t$  in  $\mathbb{R}$  that we will discuss perhaps in a tutorial.

So  $u_{tt} = c^2 u_{xx}$  in  $x$  belongs to  $\mathbb{R}$   $t$  belongs to  $0$  infinity then we have 2 conditions which are called initial conditions are Cauchy conditions that is  $u(x, 0)$  is  $\varphi(x)$   $u_t(x, 0)$  is  $\psi(x)$  is given

with this much smoothness this is what is called Cauchy problem for 1 dimensional wave equation.

**(Refer Slide Time: 02:12)**

### Main steps in solving the Cauchy problem

- 1 The wave equation (WE-1d) is transformed into its canonical form.
  - The new coordinate system is called **system of characteristic coordinates**.
- 2 General solution to the equation in the Canonical form is obtained.
- 3 Going back to the  $x, t$  coordinates, the **general solution to the wave equation (WE-1d) is obtained**.
- 4 Solution of the Cauchy problem is then obtained by imposing the initial conditions (IC-1) and (IC-2) on the general solution, which yields the **d'Alembert formula**.

So what are the main steps in solving the Cauchy problems the wave equation that is WE – 1d is transformed into its canonical form. The new coordinate system is called system of characteristic coordinates. A general solution to the equation in the canonical form is obtained because canonic form is very easy to solve and going back to the  $x, t$  coordinates. The general solution to the wave equation is obtained as the function of  $x$  and  $t$  and solution.

Or the Cauchy problem is then obtained by imposing the initial conditions IC-1 and IC-2 on the general solution that we have obtained. The solution that we finally get is what is called d'Alembert's formula.

**(Refer Slide Time: 03:00)**

# Canonical form for one dimensional wave equation

So, first point is to reduce our wave position to canonical form.

(Refer Slide Time: 03:04)

## Recall: Change of variables

Suppose that we have a change of coordinates from  $(x, t)$  to  $(\xi, \eta)$ , and vice versa, given by

$$\xi = \varphi(x, t), \quad \eta = \psi(x, t);$$

$$x = \Phi(\xi, \eta), \quad t = \Psi(\xi, \eta).$$

A function  $u(x, t)$  gets transformed to a function  $w(\xi, \eta)$  and vice versa by

$$w(\xi, \eta) = u(\Phi(\xi, \eta), \Psi(\xi, \eta)),$$

$$u(x, t) = w(\varphi(x, t), \psi(x, t)).$$

So recall about of change of variables suppose that we have a change of coordinates from  $x, t$  to  $\psi, \eta$  and vice versa given by  $\psi = \varphi(x, t)$  and  $\eta = \psi(x, t)$  and  $x = \Phi(\psi, \eta)$  and  $t = \Psi(\psi, \eta)$ . A function  $u$  gets transformed into a function in terms of  $\psi, \eta$  using these relations and vice versa. So, we are going to find an, equation satisfied by  $w$  solve it and get  $u$  using the  $w$  that is the strategy.

(Refer Slide Time: 03:41)

## How the Wave equation changes under a change of variables?

Let us transform

$$u_{tt} - c^2 u_{xx} = 0 \quad (\text{WE-1d})$$

into  $(\xi, \eta)$  coordinates.

Differentiating  $u(x, t) = w(\varphi(x, t), \psi(x, t))$  w.r.t.  $x$  and  $t$  yields

$$u_x(x, t) = w_\xi(\varphi(x, t), \psi(x, t)) \varphi_x(x, t) + w_\eta(\varphi(x, t), \psi(x, t)) \psi_x(x, t),$$

$$u_t(x, t) = w_\xi(\varphi(x, t), \psi(x, t)) \varphi_t(x, t) + w_\eta(\varphi(x, t), \psi(x, t)) \psi_t(x, t).$$

Differentiating the above set of equations once more, we get

So how does this wave equation change under change of variables? So let us transform WE-1d into psi eta coordinates. We are yet to find this coordinates we will find that so differentiate this relation  $u(x, t) = w(\varphi(x, t), \psi(x, t))$  with respect to  $x$  and  $t$  you get  $u_x$  equal to  $w$  with respect to the first variable which is  $\varphi$  and  $w$  with respect to  $x$  plus  $w$  with respect to  $\eta$  and  $\psi$  with respect to  $x$  this is the chain rule and similarly  $u_t$ .

Of course what we need is  $u_{tt}$  and  $u_{xx}$  so that we can go back and substitute the equation. So please do these computations on your own.

**(Refer Slide Time: 04:39)**

## How the Wave equation changes under a change of variables? (contd.)

$$u_{xx}(x, t) = w_{\xi\xi}(\varphi, \psi) \varphi_x^2 + 2w_{\xi\eta}(\varphi, \psi) \varphi_x \psi_x + w_{\eta\eta}(\varphi, \psi) \psi_x^2 + w_\xi(\varphi, \psi) \varphi_{xx} + w_\eta(\varphi, \psi) \psi_{xx},$$

$$u_{tt}(x, t) = w_{\xi\xi}(\varphi, \psi) \varphi_t^2 + 2w_{\xi\eta}(\varphi, \psi) \varphi_t \psi_t + w_{\eta\eta}(\varphi, \psi) \psi_t^2 + w_\xi(\varphi, \psi) \varphi_{tt} + w_\eta(\varphi, \psi) \psi_{tt},$$

where the argument of all the functions on RHS, namely  $(x, t)$ , is omitted for brevity.

So  $u_{xx}$  it will turn out to be having this expression and  $u_{tt}$  this expression the argument is  $s$   $t$  which, we are suppressing here. Otherwise equations will be in many more lines.

(Refer Slide Time: 04:58)

Substituting for  $u_{xx}, u_{tt}$  in the equation (WE-1d), we get

$$Aw_{\xi\xi} + 2Bw_{\xi\eta} + Cw_{\eta\eta} + Dw_{\xi} + Ew_{\eta} = 0,$$

where

$$A(\xi, \eta) := (\varphi_t^2 - c^2\varphi_x^2)(x, t)$$

$$B(\xi, \eta) := (\varphi_t\psi_t - c^2\varphi_x\psi_x)(x, t)$$

$$C(\xi, \eta) := (\psi_t^2 - c^2\psi_x^2)(x, t)$$

$$D(\xi, \eta) := (\varphi_{tt} - c^2\varphi_{xx})(x, t)$$

$$E(\xi, \eta) := (\psi_{tt} - c^2\psi_{xx})(x, t)$$

Of course, we need to substitute  $x = \Phi(\xi, \eta), t = \Psi(\xi, \eta).$

Let us substitute for  $u_{xx}$  and  $u_{tt}$  in a wave equation and we get an equation of this form  $x$  and  $t$  we have to substitute capital phi and capital psi.

(Refer Slide Time: 05:17)

### Canonical form

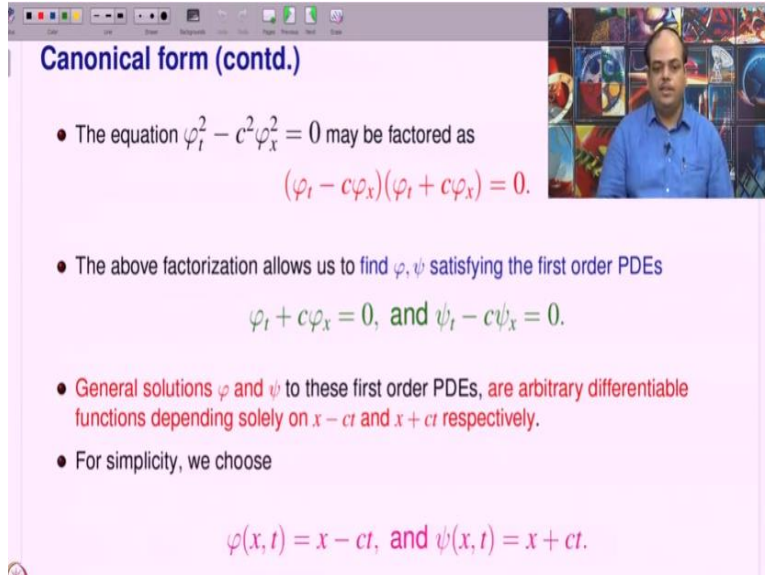

- Wave equation is a **hyperbolic equation**. To find its canonical form, we require:
  - The coefficients of  $w_{\xi\xi}$  and  $w_{\eta\eta}$  must be zero. That is,
 
$$(\varphi_t^2 - c^2\varphi_x^2)(x, t) = 0, \quad (\psi_t^2 - c^2\psi_x^2)(x, t) = 0.$$
  - Note that equations for  $\varphi$  and  $\psi$  are identical.
  - For  $\xi = \varphi(x, t), \eta = \psi(x, t)$  to define a change of coordinates,
    - we must choose solutions  $\varphi, \psi$  of  $\varphi_t^2 - c^2\varphi_x^2 = 0$  such that
 
$$\frac{\partial(\varphi, \psi)}{\partial(x, t)} \neq 0.$$

So wave equation is hyperbolic equation to find it is canonical for it require that  $w_{\psi\psi}$  and  $w_{\eta\eta}$  their coefficients must be 0. What are they? It is a coefficient of  $w_{\psi\psi}$  this is for  $w_{\eta\eta}$  we want that to be 0. But if you observe the equations are same of course this is written

for phi this is written for psi otherwise equation itself is a same. So now for psi = phi and eta = psi to define a change of coordinates phi and psi I cannot take it to the same function.

In fact what I need is this Jacobian to be non-zero so I need solutions of this equation phi and psi of this equation with this property. Because that is when I know that there is a change of coordinates, possible thanks to inverse function theorem.

**(Refer Slide Time: 06:12)**

**Canonical form (contd.)**

- The equation  $\varphi_t^2 - c^2\varphi_x^2 = 0$  may be factored as
 
$$(\varphi_t - c\varphi_x)(\varphi_t + c\varphi_x) = 0.$$
- The above factorization allows us to find  $\varphi, \psi$  satisfying the first order PDEs
 
$$\varphi_t + c\varphi_x = 0, \text{ and } \psi_t - c\psi_x = 0.$$
- General solutions  $\varphi$  and  $\psi$  to these first order PDEs, are arbitrary differentiable functions depending solely on  $x - ct$  and  $x + ct$  respectively.
- For simplicity, we choose
 
$$\varphi(x, t) = x - ct, \text{ and } \psi(x, t) = x + ct.$$

So this equation can be factored into this if you multiply you will see that phi x phi t term will get cancelled. So this if you multiply precisely this therefore what we do is that we find a fees satisfying one of these equations and psi the other equation. So any one of them is 0 product is 0 that is the logic here so we do this and very easy write down the general solutions of this equations because this is equation with constant coefficients.

So phi is a function of  $x - ct$  alone and psi is a function of  $x + ct$  alone so please checks for, yourself. We did this in the first order partial differential equations chapter so for simplicity let us take phi =  $x - ct$  psi =  $x + ct$ .

**(Refer Slide Time: 07:07)**

### Definition (characteristics)

The two families of lines

$$x - ct = \text{constant}, \quad x + ct = \text{constant}$$

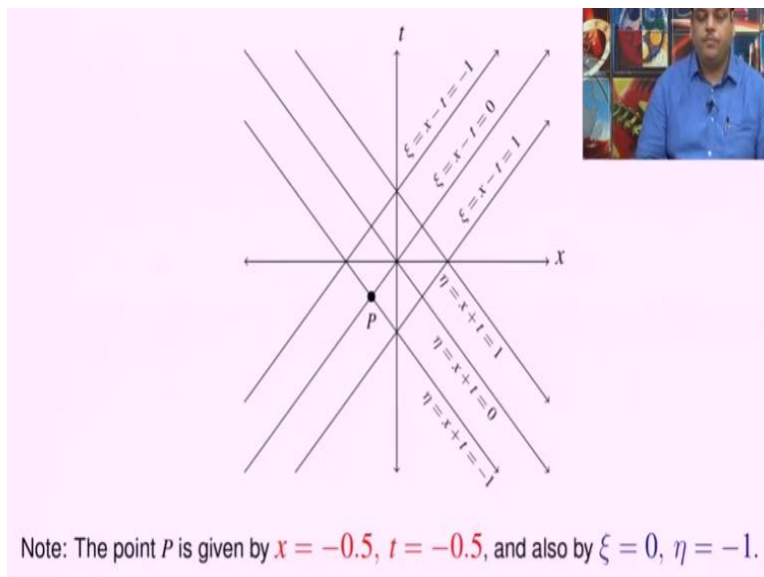

are called the **characteristics** of the one dimensional wave equation.

- The new coordinate system  $\xi = \varphi(x, t) = x - ct$ ,  $\eta = \psi(x, t) = x + ct$  is called **characteristic coordinate system**.
- Note that characteristics consist of two families of straight lines with slopes  $\pm \frac{1}{c}$ .
  - When  $c = 1$ , the two families of characteristics are **orthogonal**.
  - The **characteristic coordinates system** is an anti-clockwise rotation of  $(x, t)$ -coordinate system by  $45^\circ$ . See the Figure on next slide.

Now this is a definition these are lines  $x - ct = \text{constant}$  and  $x + ct = \text{constant}$  they are called the characteristics of the one dimensional wave equation. The new coordinate system  $\xi = x - ct$   $\eta = x + ct$  is called characteristics coordinate system. Note that characteristic consist of 2 families of straight lines having slopes plus or minus 1 by c 1 has 1 by c and the other family has  $-1$  by c each family consist of parallel lines.

So when  $c = 1$  the families are actually are orthogonal families the characteristic coordinate system is a anti clock wise rotation of the  $x$   $t$  coordinate system. We will see this in the next slide we have a picture.

**(Refer Slide Time: 08:02)**

So this is our original  $x$  and  $t$  coordinate system and this is  $\psi$  and  $\eta$   $\psi = x - t$   $\eta = x + t$  they are orthogonal because  $c = 1$ . Look at this point  $P$  in terms of  $x$   $t$  coordinates is given by  $x = -0.5$   $t = -0.5$  in terms of  $\psi$   $\eta$  it is lying on this line  $x = 3$  so  $\psi$  is 0 and  $\eta$  is  $-1$ .

(Refer Slide Time: 08:39)

### Canonical form (contd.)

In the **characteristic coordinate system** given by  $\xi = \varphi(x, t) = x - ct$ ,  $\eta = \psi(x, t) = x + ct$ , wave equation becomes

$$Aw_{\xi\xi} + 2Bw_{\xi\eta} + Cw_{\eta\eta} + Dw_{\xi} + Ew_{\eta} = 0,$$

where

$$A(\xi, \eta) := (\varphi_t^2 - c^2\varphi_x^2)(x, t) = 0$$

$$B(\xi, \eta) := (\varphi_t\psi_t - c^2\varphi_x\psi_x)(x, t) = -2c^2$$

$$C(\xi, \eta) := (\psi_t^2 - c^2\psi_x^2)(x, t) = 0$$

$$D(\xi, \eta) := (\varphi_{tt} - c^2\varphi_{xx})(x, t) = 0$$

$$E(\xi, \eta) := (\psi_{tt} - c^2\psi_{xx})(x, t) = 0$$

In this coordinate system given by  $\psi = x - ct$   $\eta = x + ct$  the wave equation becomes this we have already noted down. But now we have insisted  $A$  must be 0 similarly  $C$  is 0. And  $B$  turns out to be  $-2c^2$  the computation will give  $C = 0$   $D$  is also 0.

(Refer Slide Time: 09:05)

### Canonical form (contd.)

Thus the wave equation, in the **characteristic coordinate system** is given by,

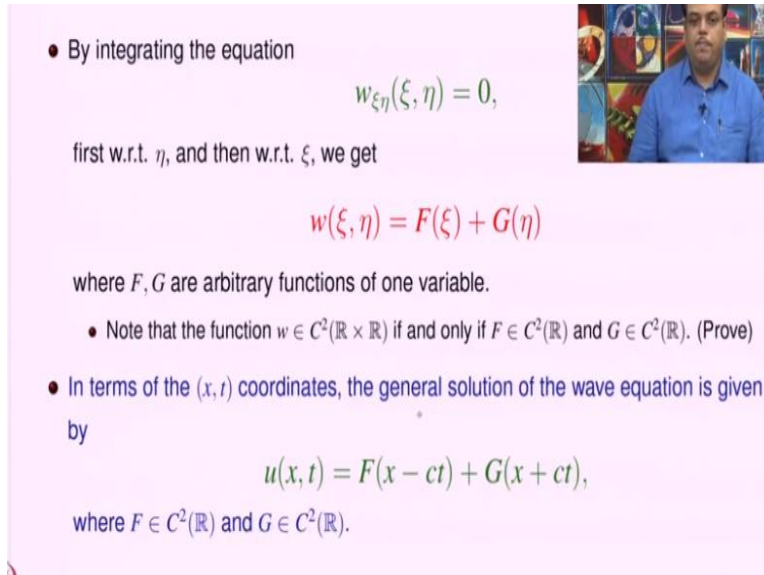

$$-4c^2w_{\xi\eta}(\xi, \eta) = 0.$$

Thus **canonical form of the homogeneous wave equation (WE-1d)** is

$$w_{\xi\eta}(\xi, \eta) = 0.$$

So therefore the equation that we have is  $-4c^2 w_{\xi\eta} = 0$  of course  $c$  is non-zero we can cancel this and you get  $w_{\xi\eta} = 0$ . This is a canonical form of the homogenous wave equation.

**(Refer Slide Time: 09:05)**

- By integrating the equation
 
$$w_{\xi\eta}(\xi, \eta) = 0,$$
 first w.r.t.  $\eta$ , and then w.r.t.  $\xi$ , we get
 
$$w(\xi, \eta) = F(\xi) + G(\eta)$$
 where  $F, G$  are arbitrary functions of one variable.
  - Note that the function  $w \in C^2(\mathbb{R} \times \mathbb{R})$  if and only if  $F \in C^2(\mathbb{R})$  and  $G \in C^2(\mathbb{R})$ . (Prove)
  - In terms of the  $(x, t)$  coordinates, the general solution of the wave equation is given by
 
$$u(x, t) = F(x - ct) + G(x + ct),$$
 where  $F \in C^2(\mathbb{R})$  and  $G \in C^2(\mathbb{R})$ .

Now we can integrate this with respect to  $\eta$  first and  $\xi$  next or even the other order is also fine. And we get this expression if integrate with respect to  $\eta$  first then what you have is  $w_{\xi}$  is a function of  $\xi$  alone and then  $w_{\xi}$  will turn out to be this  $w_{\xi} = F'(\xi) + G'(\eta)$ . So note that the function  $w$  is  $C^2$  on  $\mathbb{R} \times \mathbb{R}$  if and only if the  $F$  is  $C^2$  and  $G$  is  $C^2$ . So  $w$  is  $C^2$  function if and only if  $F$  and  $G$  are  $C^2$  functions.

So in terms of the  $x, t$  coordinates the general solution of wave equation is given by go back and substitute for  $\xi$  equal to  $x - ct$  and  $\eta = x + ct$  so we get this where  $F$  is  $C^2$  and  $G$  is  $C^2$ .

**(Refer Slide Time: 10:30)**

We proved the following result.

### Lemma (Classical solution to Wave equation)

- Let  $F \in C^2(\mathbb{R})$  and  $G \in C^2(\mathbb{R})$ .
- The function  $u$  defined by

$$u(x, t) = F(x - ct) + G(x + ct),$$

is a classical solution of the homogeneous wave equation (WE-1d).

So we prove the following result classical solution to wave equation let  $F$  belongs to  $C^2$  and  $G$  belongs to  $C^2$  the function  $u$  defined by  $u(x, t) = F(x - ct) + G(x + ct)$  is a classical solution of the homogenous wave equation. No Cauchy problem yet we have just solved the wave equation homogenous wave equation. Now we impose initial conditions on this and we determine what  $F$  and  $G$  should be in terms of the given function is  $\phi$  and  $\psi$ .

**(Refer Slide Time: 11:06)**

### Geometric interpretation: Wave propagation

To present a geometric interpretation, let us fix a time instant  $t = t_0$ .

- The graph of  $F(x + ct_0)$  is precisely the graph of  $F(x)$  shifted by  $ct_0$  units to the left.  
Thus

$F(x + ct)$  represents a *backward moving (or left moving) wave* with speed  $c$ .

- The graph of  $G(x - ct_0)$  is precisely the graph of  $G(x)$  shifted by  $ct_0$  units to the right.  
Thus

$G(x - ct)$  represents a *forward moving (or right moving) wave* with speed  $c$ .

Thus **any solution of the wave equation** is a superposition of a forward moving wave, and a backward moving wave.  $\square$

Before that we do a geometric interpretation as a wave propagation let us fix a time instant  $t = t_0$  and the graph of  $F(x + ct_0)$  is precisely graph of  $F(x)$  shifted by  $ct_0$  units to the left. Thus  $F(x + ct)$  represents a backward moving or left moving wave with speed  $c$ .

Similarly the graph of  $g$  of  $x - ct$  is precisely the graph of  $g$  of  $x$  that means shape is not changing but it is getting translated by  $ct$  units to the right side.

Thus  $G$  of  $x - ct$  represents a forward moving or right moving wave with speed  $c$  thus any solution of the wave equation is a superposition of a wave which is moving forward and another moving backward.

**(Refer Slide Time: 12:09)**

## d'Alembert formula for solution of Cauchy problem

Now let us derive the d'Alembert formula for solution of Cauchy problem.

**(Refer Slide Time: 12:14)**

### d'Alembert formula

- The general solution of the wave equation is

$$u(x, t) = F(x - ct) + G(x + ct).$$

- Imposing the initial condition  $u(x, 0) = \varphi(x)$  yields

$$F(x) + G(x) = \varphi(x).$$

- Imposing the other initial condition  $u_t(x, 0) = \psi(x)$  gives

$$-cF'(x) + cG'(x) = \psi(x).$$

The general solution of the wave equation is  $u(x,t) = F(x-ct) + G(x+ct)$  now we have to use our given Cauchy conditions  $u(x,0) = \phi(x)$ . So I put  $t = 0$  in this equation I get  $\phi(x) = F(x) + G(x)$  so this is the equation I have for  $f$  and  $g$ . Now we have another initial condition that is  $u_t(x,0) = \psi(x)$  so differentiate this equation respect to  $t$  and then put  $t = 0$ . So if you differentiate this with respect to  $t$  what you get is  $F'(x-ct)(-c) + G'(x+ct)(c)$  into  $c$ .

And when you put  $t = 0$  what you have is  $-cF'(x) + cG'(x)$  that is equal to  $\psi(x)$  therefore you have this. So we have to 2 relations connecting  $F$  and  $G$  in terms of given  $\phi$  and  $\psi$ . But this equation has  $F'$  and  $G'$  so it is better to get rid of the derivative and that is done by integrating. Integrating both sides of this equation so that left hand side becomes a combination of  $F$  and  $G$  and here already have one combination of  $F$  and  $G$  linear combination.

So these are system of 2 linear equations you will get from there we can determine  $F$  and  $G$  that is the strategy.

**(Refer Slide Time: 13:46)**

### d'Alembert formula

- Integrating the equation

$$-cF'(x) + cG'(x) = \psi(x).$$

over the interval  $[0, x]$  yields

$$-F(x) + G(x) = \frac{1}{c} \int_0^x \psi(s) ds - F(0) + G(0).$$

So let us integrate this equation between 0 to  $x$  so we get  $F + G - F + G$  from here because once you integrate from 0 to  $x$  this is actually  $-c$  times  $F'$  -  $G'$ . So that is  $F - G$  whole dash so if you integrate you get  $F - G$  at  $c$  -  $f - g$  at 0 the 0 terms have been transferred this side. And here you have integral 0 to  $x$   $\psi(s) ds$  here and then you divide with a  $c$ . So you get  $1/c$  please do this computation.

(Refer Slide Time: 14:24)

### d'Alembert formula

Substituting the expressions for  $F$  and  $G$  from

$$F(x) = \frac{1}{2}\varphi(x) - \frac{1}{2c} \int_0^x \psi(s) ds + \frac{F(0) - G(0)}{2},$$

$$G(x) = \frac{1}{2}\varphi(x) + \frac{1}{2c} \int_0^x \psi(s) ds - \frac{F(0) - G(0)}{2}$$

in  $u(x, t) = F(x - ct) + G(x + ct)$ , we get

$$u(x, t) = \frac{\varphi(x - ct) + \varphi(x + ct)}{2} + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(s) ds,$$

which is known as **d'Alembert formula**.

So we have the following 2 equations for  $F$  and  $G$  this is coming from IC-1  $F + G = \varphi$  this is come IC-2 after integration  $-F + G$  equal to this. Now if you add up you get an expression for  $G$  if you subtract you get an expression for  $F$ . So we can solve this system of linear equations and obtain  $F =$  this expression and  $G =$  this expression. Now we take these expressions for  $F$  and  $G$  and substitute in the solution  $u$  which is given in terms of  $F$  and  $G$ .

So this is the expression that we end up with  $u(x, t) = \frac{\varphi(x - ct) + \varphi(x + ct)}{2} + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(s) ds$ . This term this is a constant this is a minus of constant so it actually got cancelled. So this is known as d'Alembert formula for the solution of homogenous wave equation and the Cauchy problem where  $\varphi$  is  $u(x, 0)$   $\psi$  is  $u_t(x, 0)$ . So  $\varphi$  is  $u(x, 0)$  so  $u(x, 0)$  is called initial displacement  $\psi$  is  $u_t(x, 0)$  that is the initial velocity.

(Refer Slide Time: 15:50)

## Theorem

Let  $\varphi \in C^2(\mathbb{R})$  and  $\psi \in C^1(\mathbb{R})$ . The function  $u : \mathbb{R} \times (0, \infty)$  defined by

$$u(x, t) := \frac{\varphi(x - ct) + \varphi(x + ct)}{2} + \frac{1}{2c} \int_{x-ct}^{x+ct} \psi(s) ds$$

is a classical solution to the Cauchy problem for one dimensional wave equation.  $\square$

Proof of the theorem is a straight forward computation.

So let  $\varphi$  belongs to  $C^2$  of  $\mathbb{R}$  and  $\psi$  belongs to  $C^1$  of  $\mathbb{R}$  the function defined by the d'Alembert formula is a classical solution to the Cauchy problem this we have to check right what do you have to check  $u$  is a  $C^2$  function why is it a  $C^2$  function? Because of chain rules we have  $\varphi$  is a  $C^2$  function this is a  $C^\infty$  function  $x - ct$ . Similarly  $x + ct$  show that  $\varphi$  of  $x - ct$  is  $C^2$   $\varphi$  of  $x + ct$  is  $C^2$  as a function of  $x$  and  $t$  and  $\psi$   $C^1$  but we are integrating.

Therefore we gain one extra derivative that is why this term is  $C^2$  you can use (()) (16:33) to get third derivatives and then check that  $u$  is indeed a solution to the homogenous wave equation and putting  $t = 0$  is very easy put  $t = 0$  this integral is from  $x$  to  $x$  so this 0 this term is 0. And what we get is  $\varphi(x) + \varphi(x)$  by 2 so you get  $\varphi(x)$  differentiate with respect to  $t$  this equation and substitute  $t = 0$  you should get  $\psi(x)$ . So it is a very straight forward computation so I will leave it as an exercise for you to do it.

Please write down in detail why this  $u$  is  $C^2$  and why it satisfies the homogenous wave equation and the 2 initial conditions.

**(Refer Slide Time: 17:16)**

## Remark

- In fact, we proved that any solution of the Cauchy problem is given by d'Alembert formula.
- Thus we established that the **Cauchy problem has a unique solution, and is given by d'Alembert formula.**

**Exercise.** Go through the steps and convince yourself.

In fact if you observe closely we proved that any solution of the Cauchy problem is given by d'Alembert formula thus we established that the Cauchy problem has a unique solution and is given by d'Alembert formula. So go through the steps and convince yourself what did we do? We are given homogenous wave equation that we reduced to canonical form there is no compromise there.

Canonical form is  $C^2$  solution if and only if it is given by  $F$  of  $\psi$  +  $G$  of  $\eta$  and  $F$  and  $G$  has to be  $C^2$  no compromise there. After that we went back and substituted so everywhere there is no loss of information therefore the uniqueness is there in the proof. So please conscience yourself that we have indeed proved uniqueness and in case you are still not convinced we will give another proof later on couple of proofs later on for the uniqueness.

## Summary

- 1 Wave equation in any space dimension is already in a good canonical form.
- 2 However, in one space dimension, the wave equation has a simpler canonical form, namely  $w_{\xi\eta} = 0$ . It played a major role in deriving d'Alembert formula.
- 3 On the other hand, for Wave equation in higher space dimensions, it is **NOT clear** if there are such simpler canonical forms which help immensely in obtaining a solution to the Cauchy problem.

Let us summarize what we did in this lecture wave equation in any space dimension is already in a good canonical form  $u_{tt} - c^2 \text{Laplacian } u = 0$  you cannot ask for anything better than that. However in one space dimension the wave equation is simpler canonical form namely  $w_{\xi\eta} = 0$  and that played a major role in deriving d'Alembert formula. On the other hand for wave equation highest space dimensions that is dimension 2 onwards.

It is not clear if there are simpler canonical forms these aspects we have discussed in the chapter 3. So it is not clear if there are such simpler canonical which help immensely in obtaining a solution to Cauchy problem.

## Summary (contd.)

- 4 For higher dimensional wave equations, we adopt a totally different approach.
  - Method of Spherical means will be introduced, which helps in solving Cauchy problem for wave equation in 3 space dimensions.
  - As we shall see, d'Alembert formula also plays a role in the analysis.

So for higher dimensional wave equation what we do we adopt a totally different approach we use what is called a method of spherical means we will introduce that and that helps in solving Cauchy problem for wave equation in 3d first 3 dimensions not 2d but to 3d. As we shall see d'Alembert formula also plays a role in the analysis so using spherical means we kind of reduce the Cauchy problem in 3d to some wave equation in 1d and that is where we can use the d'Alembert formula in the solution thank you.
