**Lecture – 6.1**  
**Laplace Equation – Associated Boundary Value Problems**

Welcome to this lecture, in this lecture, we are going to discuss boundary value problems for Laplace equation, the outline of the lecture is as follows. First we derive what are called Green's identities which are derived from the divergence theorem and then we introduce boundary value problems associated to Laplace equation and study the uniqueness properties of solutions to those boundary value problems.

**(Refer Slide Time: 00:43)**

**Laplace equation in  $d$ -dimensions**

$$u_{x_1 x_1} + u_{x_2 x_2} + \dots + u_{x_d x_d} = 0.$$

Any solution to the above equation is called a **Harmonic function**.

So, Laplace equation in  $d$  space dimensions there are only space dimensions here, there is unlike the wave equation. So, Laplace equation in  $d$  dimensions is given by  $u_{x_1 x_1} + u_{x_2 x_2} + \dots + u_{x_d x_d} = 0$ , the operator on the left hand side is called Laplacian  $\Delta u$  denoted by capital delta  $\Delta u$ , that is the standard notation for a Laplacian. This is nothing but the trace of the hessian matrix of the function  $u$ , hessian in matrix recall is the matrix of second derivatives of  $u$ . So, this is the trace of that. That means sum of the diagonal terms. Any solution to the above equation is called Harmonic function.

**(Refer Slide Time: 01:33)**

**Laplace equation in 2-dimensions**

- When  $d = 2$ , the independent variables  $x_1, x_2$  are denoted by  $x = (x, y)$ .
- Thus **Laplace equation** in two independent variables is
 
$$u_{xx} + u_{yy} = 0.$$
- The nonhomogeneous problem
 
$$u_{xx} + u_{yy} = f,$$
 where  $f$  is a function of the independent variables  $x, y$  only is called the **Poisson equation**.

S. Raju, Ganesh (IIT Bombay) Partial Differential Equations Lecture 4-1 4/38

Laplace equation in 2 dimensions we are going to deal with in some of the lectures which come later on. When  $d = 2$  the independent variables  $x_1, x_2$  are denoted by  $x, y$ , that is a standard practice and we write boldface  $x$  sometimes that denotes the triple  $x, y$  in  $\mathbb{R}^2$ . This Laplace equation in 2 independent variables is nothing but  $u_{xx} + u_{yy} = 0$ . The non homogeneous problem where there is a right hand side not 0 functions, but the general function  $f$ , this equation is called Poisson equation.

So, in particular, if  $f = 0$  get back this equation, so we the difference between Poisson equation and Laplace equation is kind of blurred for us, we simply call anything as a Laplace equation. Actually Laplacian is this operator which is on the left side of both the equations, here it is a homogeneous equation, here is a non homogeneous equation and the non homogeneous equation is usually called Poisson equation. So, let us discuss, what are the Green's identities and how to derive them

**(Refer Slide Time: 02:47)**

Green's Identities play an important role in the analysis of Laplace equation. They are derived from divergence theorem.

**Theorem (Divergence theorem)**

- Let  $\Omega \subseteq \mathbb{R}^2$  be a bounded piecewise smooth domain.
- Let  $\Psi : \Omega \rightarrow \mathbb{R}^2$  be a function. Let  $\Psi = (\psi_1, \psi_2)$ .
- Let  $\psi_i \in C^1(\overline{\Omega}) \cap C(\overline{\Omega})$  for  $i = 1, 2$ .

Then

$$\int_{\Omega} \nabla \cdot \Psi(x) \, dx = \int_{\partial\Omega} \Psi \cdot \mathbf{n} \, d\sigma,$$

where  $\mathbf{n}$  is the unit outward normal to  $\partial\Omega$ .

S. Sivaji Ganesh IIT Bombay Partial Differential Equations Lecture 4.1 4/42

Green's identities play an important role in the analysis of Laplace equation, they are derived from divergence theorem. So, what is divergence theorem? It is stated for a domain  $\Omega$  which is bounded and piecewise smooth domain. We are going to use in this form, let  $\Psi$  be a function which is our 2 valued function that means,  $\Psi$  has 2 component functions  $\psi_1$  and  $\psi_2$ , it is defined on this domain  $\Omega$ .  $\Omega$  is assumed to be bounded and piecewise smooth domain we will come to that as soon as we see the formula.

And we assume that the  $\psi_i$  has this property that it is  $C^1$  of  $\overline{\Omega}$  intersection  $C$  of  $\overline{\Omega}$  it means the derivative is continuous up to the boundary of  $\Omega$ . So,  $\overline{\Omega}$  closure involves  $\Omega$  union boundary for  $\Omega$ . That means, the derivative of this function  $\psi_i$  is meaningful on the boundary of  $\Omega$  also and  $C$  of  $\overline{\Omega}$  means the functions are meaningful on the boundary of  $\Omega$ . In fact, the functions  $\psi_i$ 's are continuous on  $\overline{\Omega}$ .

Then we have this integral  $\Omega$  domain integral on the right hand side you have a integral on the boundary. So, this is divergence of  $\Psi$  dx equal to integral over boundary of  $\Omega$   $\Psi \cdot \mathbf{n} \, d\sigma$ . What is  $\mathbf{n}$ ?  $\mathbf{n}$  is a unit outward normal to boundary of  $\Omega$  and what is  $d\sigma$ ? It is the surface measure which is coming to the boundary of  $\Omega$  from the  $\Omega$  from the usual measure on  $\Omega$ . So, in order that the right hand side is meaningful, we need to assume that domain is piecewise smooth domain. We will not elaborate further on this, because you will have learned this already in course on Multivariable Calculus.

**(Refer Slide Time: 04:54)**

**Green's identities**

- Green's identities are derived using the divergence theorem and making specific choices for  $\Psi$  in

$$\int_{\Omega} \nabla \cdot \Psi(x) dx = \int_{\partial\Omega} \Psi \cdot n d\sigma.$$

- $\Omega \subseteq \mathbb{R}^2$  is assumed to be a bounded piecewise smooth domain.
- $n$  denotes the unit outward normal to  $\partial\Omega$ .
- The functions  $u, v$  appearing in Green's identities are assumed to be

$$u, v \in C^2(\bar{\Omega}) \cap C^1(\bar{\Omega}),$$

to make sure that integrals appearing in them are meaningful.

3.9xij Ganesh IIT Bombay Partial Differential Equations Lecture 6.1 7/02

So, Green's identities they are derived using the divergence theorem and making specific choices for psi in this conclusion of the divergence theorem. So, choosing different psi's will give you different identities. And omega is assumed to be a bounded piecewise smooth domain, n denotes the unit outward normal to boundary omega, the functions u v appearing in Green's identities are assumed to be of this type  $C^2$  of omega bar intersection  $C^1$  of omega bar. We have already seen the space on the previous slide.

This means that the functions, the second derivatives are also continuous on omega bar that is the meaning of  $C^2$  of omega bar. To make sure that the integrals appearing in them are meaningful, first of all this integral to make sense psi x inside the integrand is continuous on omega bar. And that is guaranteed if psi is  $C^1$  of omega bar later on we are going to see an integral which feature second derivatives as the integrand that is what we are assuming  $C^2$  of omega bar it will be very clear from the context. These hypotheses are made, so that it is varied for all Green's identities.

**(Refer Slide Time: 06:14)**

Applying Divergence theorem

$$\int_{\Omega} \nabla \cdot \Psi(\mathbf{x}) \, d\mathbf{x} = \int_{\partial\Omega} \Psi \cdot \mathbf{n} \, d\sigma,$$

with  $\Psi = \nabla u$  yields

**Green's Identity-I**

$$\int_{\Omega} \Delta u(\mathbf{x}) \, d\mathbf{x} = \int_{\partial\Omega} \partial_{\mathbf{n}} u \, d\sigma.$$

8. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 8/32

For some of them, we do not require all the hypothesis. So, now, if you apply a divergence theorem with  $\psi = \text{grad } u$ , what we get is called Green's identity of 1. So, divergence of  $\psi$  is now, divergence of  $\text{grad } u$  that is Laplacian  $u$  and  $\text{grad } u \cdot \mathbf{n}$  is precisely the normal derivative of  $u$   $\text{d}u \cdot \mathbf{n}$ , so, this is Green's identities one.

**(Refer Slide Time: 06:44)**

Applying Divergence theorem

$$\int_{\Omega} \nabla \cdot \Psi(\mathbf{x}) \, d\mathbf{x} = \int_{\partial\Omega} \Psi \cdot \mathbf{n} \, d\sigma,$$

with  $\Psi = v \nabla u - u \nabla v$  yields

**Green's Identity-II**

$$\int_{\Omega} (v \Delta u - u \Delta v)(\mathbf{x}) \, d\mathbf{x} = \int_{\partial\Omega} (v \partial_{\mathbf{n}} u - u \partial_{\mathbf{n}} v) \, d\sigma$$

8. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 9/32

Now, if you apply divergence theorem with this choice of  $\psi$ , we get Green's identities 2. So, it is integral over  $\Omega$   $v \Delta u - u \Delta v$  of  $\mathbf{x} \, d\mathbf{x} =$  an integral on the boundary  $v \text{d}u \cdot \mathbf{n} - u \text{d}v \cdot \mathbf{n} \, d\sigma$ .

**(Refer Slide Time: 07:08)**

Applying Divergence theorem

$$\int_{\Omega} \nabla \cdot \Psi(\mathbf{x}) \, d\mathbf{x} = \int_{\partial\Omega} \Psi \cdot \mathbf{n} \, d\sigma,$$

with  $\Psi = v \nabla u$  yields

### Green's Identity-III

$$\int_{\Omega} \nabla u \cdot \nabla v \, d\mathbf{x} = \int_{\partial\Omega} v \partial_{\mathbf{n}} u \, d\sigma - \int_{\Omega} v \Delta u \, d\mathbf{x}.$$

9. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 18/32

If you apply divergence theorem with  $\psi = v \operatorname{grad} u$ , you get Green's identities 3, which is integral over  $\Omega$  of  $\operatorname{grad} u \cdot \operatorname{grad} v \, d\mathbf{x} = \int_{\partial\Omega} v \operatorname{div} u \, d\sigma - \int_{\Omega} v \operatorname{Laplacian} u \, d\mathbf{x}$ . In fact, this identity we have used many times before which we call it as integration by Poisson's formula. If you notice here the derivative on  $v$  shifting to the derivative on  $u$  on  $\operatorname{grad} u$ , which is giving you a Laplacian  $u$ ,  $\operatorname{grad}$  when it goes to the  $\operatorname{grad} u$ , it becomes divergence. So, you get  $v \operatorname{Laplacian} u$  and here is the boundary term. So, let us now discuss some of the boundary value problems for Laplace equation.

**(Refer Slide Time: 08:01)**

### Boundary value problems (BVPs) for Laplace equation

On a bounded domain  $\Omega$  with piecewise smooth boundary  $\partial\Omega$ , we will consider the following three BVPs

- **Dirichlet BVP:** Unknown function is prescribed on  $\partial\Omega$ .
- **Neumann BVP:** Normal derivative of the unknown function is prescribed on  $\partial\Omega$ .
- **Robin BVP:** A linear combination of the unknown function and its normal derivative is prescribed on  $\partial\Omega$ .

9. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 18/32

On a bounded domain  $\Omega$  with piecewise smooth boundary of  $\Omega$ , it is the boundary of  $\Omega$  is denoted by  $\partial\Omega$ , we will consider the following 3 boundary value problems, what are they? Dirichlet boundary value problem unknown function is prescribed

on boundary of omega here and then we have a Neumann boundary value problem in which normal derivative of the unknown function is prescribed on boundary of omega.

Then we have a Robin boundary value problem, which sometimes is also called a third boundary value problem, in this a mix of the unknown function and its normal derivative are prescribed. So, a linear combination of the unknown function and its normal derivative is prescribed on boundary of omega.

**(Refer Slide Time: 08:51)**

**BVP 1: Dirichlet Problem**

Given functions  $f, g,$

**Dirichlet Problem** consists of solving the boundary value problem

$$\Delta u = f \quad \text{in } \Omega,$$
$$u = g \quad \text{on } \partial\Omega.$$

S. Sridhar Ganesh, IIT Bombay Partial Differential Equations Lecture 6.1 10/32

So, let us see what is the Dirichlet boundary value problem? So, this is BVP 1 boundary value problem 1 Dirichlet problem. Given functions  $f$  and  $g$ , Dirichlet problem consists of solving the boundary value problem, it consists of solving the Poisson's equation Laplacian  $u = f$  in omega and  $u = g$  on the boundary of omega. That means, the unknown function should agree with the pre prescribed function  $g$  on the boundary of omega and Laplacian  $u$  should coincide with the prescribed function  $f$  in omega is what we want.

**(Refer Slide Time: 09:28)**

**Solution to Dirichlet BVP**

Let  $f \in C(\Omega)$ , and  $g \in C(\partial\Omega)$ .

A function  $\varphi \in C^2(\Omega) \cap C(\bar{\Omega})$  is said to be a solution to Dirichlet BVP

$$\begin{aligned} \Delta u &= f \quad \text{in } \Omega, \\ u &= g \quad \text{on } \partial\Omega. \end{aligned}$$

if

- the function  $\varphi$  is a solution to  $\Delta u = f$ . That is, for each  $x \in \Omega$ ,

$$\Delta\varphi(x) = f(x)$$

holds, and

- for each  $x \in \partial\Omega$ , the equality  $\varphi(x) = g(x)$  holds.

S. Stepić, Ganesh, JIT Bormay Partial Differential Equations Lecture 6.1 14/22

What is the meaning of a solution to Dirichlet boundary value problem? Here we have to start assuming something on the data, let  $f$  be a continuous function and  $g$  also be a continuous function on  $\Omega$  and on boundary of  $\Omega$  respectively, a function  $\varphi$  which is  $C^2$  on  $\Omega$  and continuous on  $\bar{\Omega}$ . You will actually see why this hypothesis coming here on  $\varphi$  will be very clear once you see the definition is said to be a solution to a boundary value problem. If Laplacian  $u = f$  in  $\Omega$  and  $u = g$  on boundary of  $\Omega$ .

This is the statement of the Dirichlet boundary value problem. If the function  $\varphi$  is a solution to Laplacian  $u = f$ , it means that for each  $x$  in  $\Omega$  Laplacian  $\varphi$  of  $x$  should be equal to  $f$  of  $x$ . So, in order that the left hand side makes sense, we are assuming  $\varphi \in C^2(\Omega)$  that is  $\varphi \in C^2(\Omega)$ . Now, there is a second condition that is a boundary condition for each  $x$  in boundary of  $\Omega$   $\varphi$  of  $x$  should be equal to  $g$  of  $x$ .

If  $\varphi$  is continuous up to boundary that is  $C^0$  on  $\bar{\Omega}$ , then values of  $\varphi$  for points  $x$ , which are in the boundary is meaningful, and asking that is equal to  $g$  of  $x$  is meaningful. So, that is the reason why we have to put these spaces naturally.

**(Refer Slide Time: 10:50)**

**BVP 2: Neumann Problem**

Given functions  $f, g$ ,

**Neumann Problem** consists of solving the boundary value problem

$$\Delta u = f \quad \text{in } \Omega,$$

$$\partial_{\mathbf{n}} u = g \quad \text{on } \partial\Omega.$$

S. Sivaji Ganesh (IT Bombay) Partial Differential Equations Lecture 4.1 11/32

Now, let us look at the second boundary value problem called Neumann problem. So, here given functions  $f$  and  $g$ . Neumann problem consists of solving the boundary value problem, Laplacian  $u = f$  in  $\Omega$ , and the normal derivative equal to  $g$  on boundary of  $\Omega$ ,  $g$  and  $f$  are prescribed, they are given to us.

**(Refer Slide Time: 11:14)**

**Solution to Neumann BVP**

Let  $f \in C(\Omega)$ , and  $g \in C(\partial\Omega)$ .

A function  $\varphi \in C^2(\Omega) \cap C^1(\bar{\Omega})$  is said to be a solution to Neumann BVP

$$\Delta u = f \quad \text{in } \Omega,$$

$$\partial_{\mathbf{n}} u = g \quad \text{on } \partial\Omega.$$

if

- the function  $\varphi$  is a solution to  $\Delta u = f$ . That is, for each  $x \in \Omega$ ,

$$\Delta\varphi(x) = f(x)$$

holds, and

- for each  $x \in \partial\Omega$ , the equality  $\partial_{\mathbf{n}} \varphi(x) = g(x)$  holds.

S. Sivaji Ganesh (IT Bombay) Partial Differential Equations Lecture 4.1 11/32

What is the meaning of a solution to the Neumann boundary value problem, assume that  $f$  is continuous on  $\Omega$  and  $g$  is continuous on boundary of  $\Omega$ . A function  $\varphi$  which is  $C^2$  of  $\Omega$  intersection  $C^1$  of  $\bar{\Omega}$  he said to be a solution to Neumann boundary value problem. If the function  $\varphi$  is a solution to Laplacian  $u = f$ , that is why we are going to assume  $\varphi \in C^2(\Omega)$  because of this Laplacian  $\varphi$  at every point  $x$  in  $\Omega$  should be equal to  $f$  of  $x$ .

Now, we have the boundary condition which involves the normal derivative. Normal derivative is nothing but gradient  $u \cdot n$ . It is a directional derivative in the direction of the normal. For that reason, we need  $C^1$  of  $\bar{\Omega}$  that means derivatives are also continuous up to boundary and hence this is meaningful. So,  $\text{div } \nabla \phi$  of  $x$  is meaningful, because  $\phi$  is  $C^1$  of  $\bar{\Omega}$ . And hence, we can ask that it should be equal to  $g$ , that is why the notion of solution to Neumann problem is like this  $\phi$  should be in this space.

**(Refer Slide Time: 12:27)**

**BVP 3: Third Boundary Value Problem**  
**Robin Problem**

Given functions  $f, g, \alpha \in \mathbb{R}$ ,

**Robin Problem** consists of solving the boundary value problem

$$\Delta u = f \quad \text{in } \Omega,$$

$$u + \alpha \frac{\partial u}{\partial n} = g \quad \text{on } \partial\Omega.$$

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 8.1 17/32

Now, let us look at the third boundary value problem, which is also known as Robin problem. Given functions  $f$ ,  $g$ , and  $\alpha$  is a real number. Robin problem consists of solving the boundary value problem equation is Poisson's equation in  $\Omega$ , boundary condition is a combination of  $u$  and the normal derivative of  $u$ ,  $u + \alpha \text{div } \nabla u = g$  on boundary of  $\Omega$ .

**(Refer Slide Time: 12:56)**

**Solution to Robin BVP**

Let  $f \in C(\Omega)$ , and  $g \in C(\partial\Omega)$ .

A function  $\varphi \in C^2(\Omega) \cap C^1(\bar{\Omega})$  is said to be a solution to

$$\begin{aligned} \Delta u &= f && \text{in } \Omega, \\ u + \alpha \partial_{\mathbf{n}} u &= g && \text{on } \partial\Omega. \end{aligned}$$

if

- the function  $\varphi$  is a solution to  $\Delta u = f$ . That is, for each  $x \in \Omega$ ,

$$\Delta \varphi(x) = f(x)$$

holds, and

- for each  $x \in \partial\Omega$ , the equality  $\varphi(x) + \alpha \partial_{\mathbf{n}} \varphi(x) = g(x)$  holds.

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 8.1 14/32

What is the definition of a solution to Robin boundary problem? Let  $f$  be a continuous function on  $\Omega$  and  $g$  be a continuous function on the boundary of  $\Omega$ . A function  $\varphi \in C^2(\Omega) \cap C^1(\bar{\Omega})$  is said to be a solution to Robin boundary value problem if  $\Delta \varphi = f$  in  $\Omega$  and  $\varphi + \alpha \partial_{\mathbf{n}} \varphi = g$  on  $\partial\Omega$ . This is natural, because this is coming from the requirement of Laplacian  $\Delta \varphi = f$  and this will come because the requirement of the boundary condition. So, this function  $\varphi$  is said to be a solution to Robin boundary value problem.

If the function  $\varphi$  is a solution to a Laplacian  $\Delta u = f$  which means for every  $x \in \Omega$   $\Delta \varphi(x) = f(x)$ , there is a reason why we assume  $\varphi \in C^2(\Omega)$ . And second condition is the boundary condition for every  $x$  on the boundary of  $\Omega$ , the equality  $\varphi(x) + \alpha \partial_{\mathbf{n}} \varphi(x) = g(x)$  holds in order that the left hand side is meaningful, we have assumed that  $\varphi \in C^1(\bar{\Omega})$ .

**(Refer Slide Time: 14:03)**

**Remark**

- As per the definition of Dirichlet BVP, the problem is posed on a bounded domain  $\Omega$ .
- The domain  $\Omega$  is bounded (enclosed) by the boundary  $\partial\Omega$ .
- For this reason, Dirichlet problem is also called an **interior Dirichlet problem**.
- On the other hand, there are BVPs which are posed on domains which are complements of bounded domains.
  - Laplace equation is to be solved on a domain  $\Omega$ , which is the complement of a bounded domain.

S. Sivaaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 4.1 11/52

Remark as per the definition of Dirichlet boundary value problem, the problem is posed on a bounded domain  $\Omega$ . In fact, the other 2 boundary value problems are also posed on bounded domains by definition. The domain  $\Omega$  is bounded means what enclosed by the boundary of  $\Omega$ , for this reason Dirichlet boundary value problem is also called an interior Dirichlet problem. Similarly, the other notions we can say interior Neumann problem, interior Robin problem.

On the other hand, there are boundary value problems which are posed on domains which are complements of bounded domains. Laplace equation is to be solved on a domain  $\Omega$  which is the complement of a bounded domain, for example, my  $\Omega$  is here. This is my  $\Omega$  it is a complement of this set which is inside. And this is my boundary of  $\Omega$ , this curve is my boundary of  $\Omega$ , I am drawing the picture in the plane obviously.

So,  $\Omega$  is outside this outside region which is here, this is boundary of  $\Omega$ . So, we need to solve Laplacian  $u$ , let us say equals to  $f$  outside and here we are prescribing  $u = g$  for example, on boundary of  $\Omega$ .

**(Refer Slide Time: 15:40)**

**Remark**

- 1 As per the definition of Dirichlet BVP, the problem is posed on domain  $\Omega$ .
- 2 The domain  $\Omega$  is bounded (enclosed) by the boundary  $\partial\Omega$ .
- 3 For this reason, Dirichlet problem is also called an **interior Dirichlet problem**.
- 4 On the other hand, there are BVPs which are posed on domains which are complements of bounded domains.
  - Laplace equation is to be solved on a domain  $\Omega$ , which is the complement of a bounded domain.
  - The unknown is prescribed on the boundary  $\partial\Omega$ .
  - Such BVPs are called **exterior Dirichlet problems**.

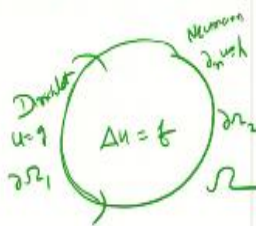

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 15/32

Unknown function is prescribed on the boundary for domain  $\Omega$ . Such boundary value problems are called exterior Dirichlet problems, similarly exterior Neumann problems, exterior Robin problems.

**(Refer Slide Time: 15:53)**

**Remark (contd.)**

- 1 Other kinds of BVPs possible.
  - On different parts of the boundary  $\partial\Omega$ , different boundary conditions may be prescribed.

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 16/32

Other kinds of boundary value problems are also possible on different parts of the boundary, you prescribe different boundary conditions. For example, this is my domain  $\Omega$  then I consider this part, let us call this boundary of domain part 1, this is boundary of domain part 2. So, here I can ask  $u = g$  here I can ask  $\frac{\partial u}{\partial n} = h$ . I want to solve Laplacian equation in domain  $\Omega = f$  in domain  $\Omega$ . And I asked that on this piece,  $u$  must be equal to  $g$  that is the Dirichlet boundary condition. On this piece,  $\frac{\partial u}{\partial n} = h$  that is a Neumann condition.

**(Refer Slide Time: 16:49)**

**Remark (contd.)**

- Other kinds of BVPs possible.
  - On different parts of the boundary  $\partial\Omega$ , different boundary conditions may be prescribed.
  - Such BVPs are called mixed BVPs
  - We will not be studying such BVPs in this course.
- Cauchy-Kowalewski theorem guarantees that a solution to an analytic Cauchy problem for an elliptic equation exists and the solution is unique (locally). This problem is not always well-posed.  $\square$

S. Sivaji Ganesh (IT Bombay) Partial Differential Equations Lecture 6.1 21/32

Such boundary value problems are called mixed boundary value problems, we will not be studying such problems in this course. Cauchy Kowalewski theorem these a comment about the initial value problem, Cauchy Kowalewski theorem guarantees that a solution to an analytic Cauchy problem for an elliptic equation in particular Laplace equation exists and the solution is unique locally. This problem is not always well posed, we are going to see towards the end of our discussion on Laplace equation, an example of well posed Cauchy problem for Laplace equation.

**(Refer Slide Time: 17:27)**

**Compatibility of data for Neumann problem**

$$\Delta u = f \text{ in } \Omega$$

$$\partial_n u = g \text{ on } \partial\Omega$$

$f \text{ } g$

S. Sivaji Ganesh (IT Bombay) Partial Differential Equations Lecture 6.1 21/32

Now, the Neumann problem that we have namely Laplacian  $u = f$  and  $\partial_n u = g$ , this is in  $\Omega$ , this is on boundary of  $\Omega$ . If this problem has a solution,  $f$  and  $g$  are tied up with some relation, so you cannot have arbitrary  $f$  and  $g$  for which the Neumann boundary value problem has a solution. In other words, if the Neumann boundary value problem has a

solution  $f$  and  $g$  must be compatible with each other in the sense that we are going to soon describe.

**(Refer Slide Time: 18:11)**

**Compatibility of data for Neumann problem**

For a Neumann BVP to admit a solution, the data  $f, g$  must be compatible.

**Lemma**

Let  $f \in C(\Omega)$ , and  $g \in C(\partial\Omega)$ .

If  $u \in C^2(\bar{\Omega})$  is a solution to Neumann BVP on  $\Omega$ , then

$$\int_{\Omega} f(\mathbf{x}) \, d\mathbf{x} = \int_{\partial\Omega} g(\mathbf{y}) \, d\sigma(\mathbf{y}).$$

Partial Differential Equations Lecture 6.1 21/32

For a Neumann boundary value problem to admit a solution, the data  $f$  and  $g$  must be compatible. That is written in the form of a Lemma, it does not mean it is a big result. It is a simple observation, just to remember the observation, so, that we can recall whenever we want, we record them as a Lemma or as a theorem in this case, it is a Lemma. Let  $f$  be  $C$  of  $\Omega$ , we have to assume something more so, for in the definition of the problem we need a  $C$  of  $\Omega$  only.

But here we are asking for  $C$  of  $\Omega$ , because the tools that we are going to use will involve the continuity up to boundary. In fact, we are going to have certain integrals for them to make sense we need this assumption. And  $g$  in  $C$  of boundary of  $\Omega$ , if  $u$  belonging to  $C^2$  of  $\Omega$  is a solution to Neumann boundary value problem and  $\Omega$ , then integral over  $\Omega$  of  $f \, dx =$  integral over boundary of  $g$ ,  $g$  is defined on the boundary. So, integrate on the boundary,  $f$  is defined in  $\Omega$  so, integrate on  $\Omega$  both of them must be equal.

**(Refer Slide Time: 19:22)**

**Proof of lemma**

Integrating both sides of the equation  $\Delta u = f$  on  $\Omega$  yields

$$\int_{\Omega} f(x) dx = \int_{\Omega} \Delta u(x) dx.$$

Applying Green's identity-I

$$\int_{\Omega} \Delta u(x) dx = \int_{\partial\Omega} \partial_{\mathbf{n}} u d\sigma,$$

the integral on the RHS of the equation at the top of this slide becomes

$$\int_{\Omega} \Delta u(x) dx = \int_{\partial\Omega} \partial_{\mathbf{n}} u(y) d\sigma(y).$$

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 22/32

So, integrate both sides of this equation Laplacian  $u = f$  on  $\omega$  what we get is this I have exchanged the sides. So, integral of  $f$  over  $\omega$  = integral of Laplacian  $n u$  over  $\omega$  fine. Now, applying Green's identity this right hand side integral can be written as this integral over boundary of  $\omega$   $\text{d}ou n u d \sigma$ . The integral on the right hand side does become this same, but now I know what is  $\text{d}ou n u$

**(Refer Slide Time: 20:07)**

**Proof of lemma (contd.)**

Since  $u$  solves Neumann BVP,  $\partial_{\mathbf{n}} u = g$ ,  $\Delta u = f$ . Thus, the equation

$$\int_{\Omega} \Delta u(x) dx = \int_{\partial\Omega} \partial_{\mathbf{n}} u(y) d\sigma(y)$$

reduces to

$$\int_{\Omega} f(x) dx = \int_{\partial\Omega} g(y) d\sigma(y). \quad \square$$

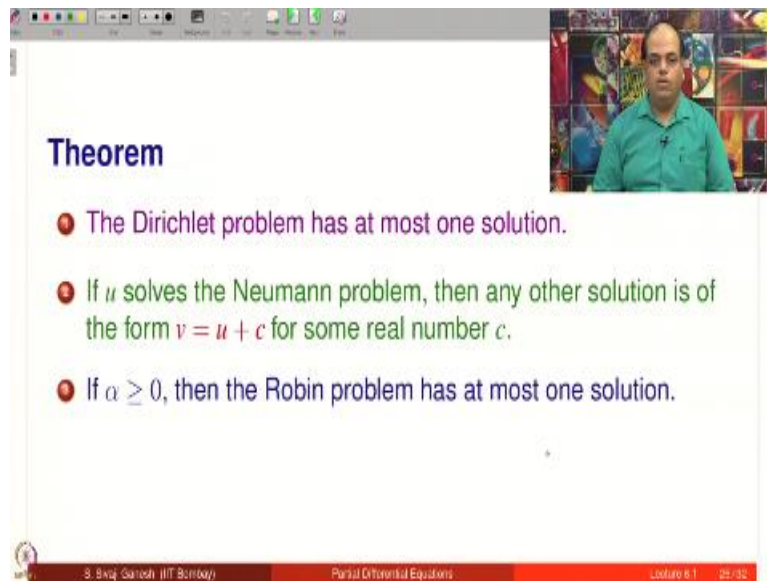

In particular, if  $u$  is a solution to Neumann BVP with  $f = 0$

S. Sivaji Ganesh (IIT Bombay) Partial Differential Equations Lecture 6.1 22/32

Since  $u$  solves the Neumann problem,  $\text{d}ou n u$  is  $g$  and Laplacian  $u$  is  $f$ . Therefore, we have this equation reducing to an equation where  $f$  is here and  $g$  is here. So, thus we have proved the Lemma. In particular, if  $f$  is 0 that is you are looking at the homogeneous Laplace equation Laplacian  $u$  equal to 0 that means  $f$  is 0, then integral of  $g$  over boundary must be 0. Now, let us discuss some uniqueness properties of solutions to the 3 boundary value problems that we have just introduced.

(Refer Slide Time: 20:54)

**Theorem**

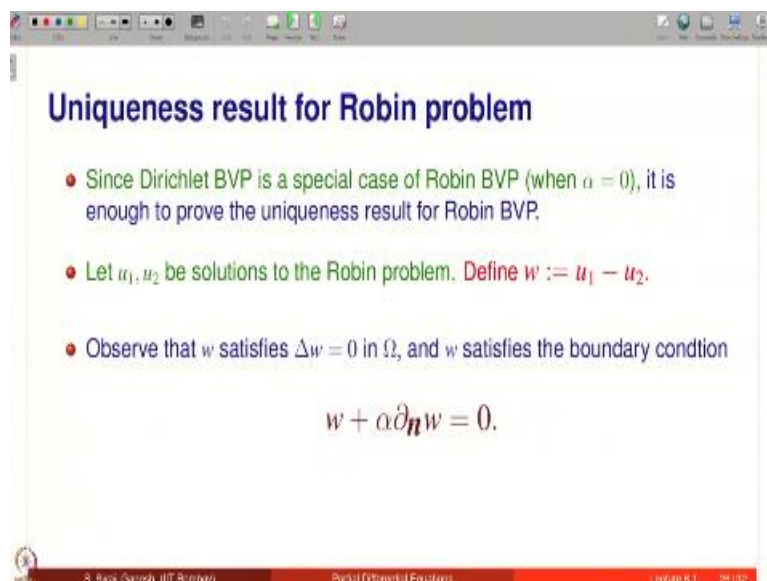

- The Dirichlet problem has at most one solution.
- If  $u$  solves the Neumann problem, then any other solution is of the form  $v = u + c$  for some real number  $c$ .
- If  $\alpha \geq 0$ , then the Robin problem has at most one solution.

3. Sivaji Ganesh IIT Bombay Partial Differential Equations Lecture 8.1 20/32

The Dirichlet boundary value problem has at most 1 solution, remember here we are not saying about existence at all, we are just saying it has at most 1 solution. That means, if it has a solution, then it has exactly 1 solution. That is the correct conclusion from here. And, if you solve some Neumann problem, then any other solution looks like  $u + c$  where  $c$  is a constant. In other words, difference of any 2 solutions to Neumann problem is a constant.

And for the Robin problem, we have to assume something an alpha. If alpha is greater than or equal to 0, then the Robin problem has at most 1 solution. Recall the Robin problem reduces to Dirichlet problem in  $\alpha = 0$ . So, proving 3 is enough to prove 1. So, what we do is we just prove 3 and then we prove 2.

(Refer Slide Time: 21:53)

**Uniqueness result for Robin problem**

- Since Dirichlet BVP is a special case of Robin BVP (when  $\alpha = 0$ ), it is enough to prove the uniqueness result for Robin BVP.
- Let  $u_1, u_2$  be solutions to the Robin problem. Define  $w := u_1 - u_2$ .
- Observe that  $w$  satisfies  $\Delta w = 0$  in  $\Omega$ , and  $w$  satisfies the boundary condition

$$w + \alpha \partial_{\mathbf{n}} w = 0.$$

3. Sivaji Ganesh IIT Bombay Partial Differential Equations Lecture 8.1 21/32

As I have already mentioned Dirichlet boundary value problem is a special case of Robin boundary value problem, it is enough to prove the uniqueness result for Robin boundary value problem. Please note I am calling here uniqueness result by this what I mean is that this problem admits at most one solution. So, I assume that  $u_1$  and  $u_2$  are solutions to the Robin problem. The uniqueness proofs always proceed like this. You take the difference of  $u_1$  and  $u_2$  and show that, that is 0.

So, therefore, you define a  $w$  which is  $u_1 - u_2$ , we want to show that  $w$  is 0. Observed that  $w$  satisfies Laplacian  $w = 0$  because Laplacian  $u_1 = f$ , Laplacian  $u_2 = f$  therefore, Laplacian  $w$  is a difference of Laplacian  $u_1$  and Laplacian  $u_2$  both of them are  $f$  therefore, Laplacian  $w$  is 0, in other words  $w$  is a harmonic function in  $\Omega$ . And  $w$  satisfies the boundary condition  $w + \alpha \text{doutn} w = 0$  because  $u_1$  satisfies the boundary condition with the same  $g$  and  $u_2$  also satisfied with the same  $g$  therefore, the difference will satisfy 0, because this is linear in  $w$ . So, this is the boundary condition satisfied by  $w$ .

**(Refer Slide Time: 23:17)**

**Uniqueness result for Robin problem (contd.)**

- Using the Green's identity-III

$$\int_{\Omega} \nabla u \cdot \nabla v \, dx = \int_{\partial\Omega} v \partial_n u \, d\sigma - \int_{\Omega} v \Delta u \, dx$$

with  $u = v = w$ , we get

$$\int_{\Omega} |\nabla w|^2 \, dx = -\alpha \int_{\partial\Omega} (\partial_n w)^2 \, d\sigma.$$

- In the last equation, the LHS is non-negative while the RHS is non-positive. Therefore, both LHS and RHS must be zero.
- This implies that  $\nabla w = 0$  in  $\Omega$

S. Raju, Sarath, IIT Bombay Partial Differential Equations Lecture 8.1 23/28

So, using the Green's identities 3 with this is the Green's identities 3, we are going to use this with  $u = v = w$ . So, the left hand side will be integral  $\Omega$  grad  $w$  dot grad  $w$  that is mod grad  $w$  square, right hand side Laplacian  $w$  is 0, so, this term is not there. So, what we have is this term? That is  $w$  into  $\text{doutn} w$   $d$  sigma. Using the boundary condition, we get integral over boundary for  $\Omega$   $w$   $\text{doutn} w$  equal to this quantity please check that.

In the last equation, the left hand side is non negative because integrand is non negative, right hand side the integral is non negative, alpha is non negative therefore, the product is non

negative but there is a minus sign. So, it is non positive. So, we have a non negative quantity equal to a non positive quantity which is possible if and only if both sides are 0. That means what?  $\text{Grad } w = 0$  on  $\Omega$ ,  $\text{dov } n w = 0$  on boundary of  $\Omega$ .

**(Refer Slide Time: 24:32)**

**Uniqueness result for Robin problem (contd.)**

- On the last slide, we proved that  $\nabla w = 0$  in  $\Omega$  and also  $\partial_n w = 0$  on  $\partial\Omega$ .
- Since  $\nabla w = 0$  in  $\Omega$ ,  $w$  must be a constant function.
- Since  $\partial_n w = 0$  on  $\partial\Omega$ , in view of the boundary condition  $w + \alpha \partial_n w = 0$ , we conclude that  $w = 0$  on  $\partial\Omega$ .
- Since  $w \in C(\bar{\Omega})$ , it follows that  $w = 0$  in  $\Omega$ .
- Thus we conclude that Robin problem has at most one solution. □

S. Baidy, Sarosh (IIT Bombay) Partial Differential Equations Lecture 6.1 24/32

On the last slide we have proved that  $\text{grad } w = 0$  in  $\Omega$  and also the normal derivative of  $w = 0$  on the boundary of  $\Omega$ . Since gradient of  $w = 0$  in  $\Omega$ ,  $w$  must be a constant function. Now, since the normal derivative is 0 on boundary of  $\Omega$ , if we use the boundary condition, we get  $w = 0$  on the boundary of  $\Omega$ , but what is  $w$ ?  $w$  is continuous up to boundary,  $w$  belongs to  $C$  of  $\Omega$  bar,  $w$  is a constant and it is 0 on the boundary. Therefore  $w$  must be 0 in  $\Omega$  also. In other words, we have Robin problem has at most one solution.

**(Refer Slide Time: 25:19)**

**Uniqueness result for Neumann problem (contd.)**

- Using the Green's identity-III

$$\int_{\Omega} \nabla u \cdot \nabla v \, dx = \int_{\partial\Omega} v \partial_n u \, d\sigma - \int_{\Omega} v \Delta u \, dx$$

with  $u = v = w$ , we get

$$\int_{\Omega} |\nabla w|^2 \, dx = \int_{\partial\Omega} w \partial_n w \, d\sigma = 0$$

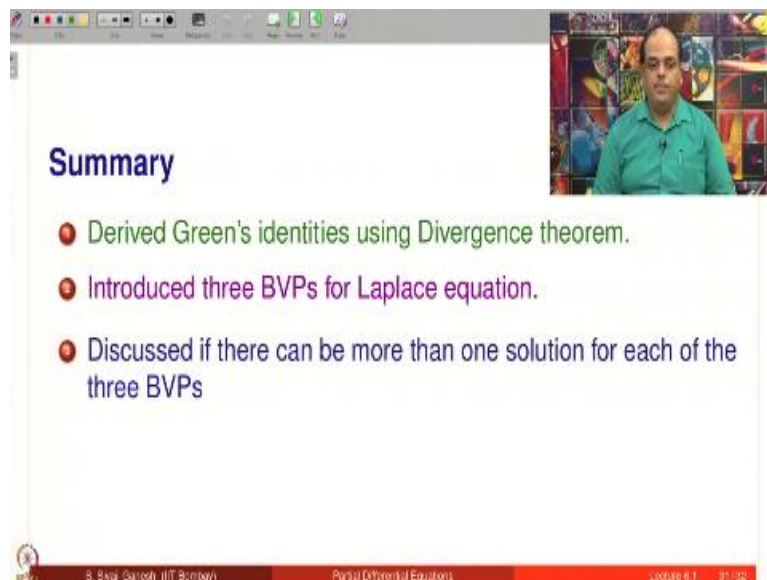

- This implies that  $\nabla w = 0$  in  $\Omega$ . This means that  $w$  is a constant function.
- That is,  $u_1 - u_2$  is a constant function. □

S. Baidy, Sarosh (IIT Bombay) Partial Differential Equations Lecture 6.1 25/32

Now let us look at Neumann problem. Let  $u_1, u_2$  be solutions to Neumann problem. Consider the difference  $u_1 - u_2$ , call it  $w$ , look at the problems satisfied by  $w$ . Laplacian  $w$  will be equal to 0 and normal derivative  $w = 0$  on the boundary of  $\Omega$ . Now using once again, Green's identities 3 with  $u = v = w$ , we have integral over  $\Omega$   $\text{mod } \text{grad } w$  square that is coming from the left hand side. On the right hand side as before Laplacian  $w$  is 0. So, second term drops out, what you have is this term?

Which I have written here,  $\int_{\Omega} \text{div } w \, dx$ , but  $\text{div } w$  is 0, therefore, this integral is 0. This means  $\text{grad } w = 0$  in  $\Omega$ , that is all we have information nothing more. If  $\text{grad } w$  is 0  $w$  must be a constant function. That means  $u_1 - u_2$  is a constant function therefore  $u_1 = u_2 + \text{constant}$ .

**(Refer Slide Time: 26:24)**

Let us summarize what we did in this lecture, we have derived Green's identities using divergence theorem, introduced 3 boundary value problems for Laplace equation, discussed if there can be more than 1 solution for each of the 3 BVPs. Thank you.
