Lecture – 12
Statistical Inference

Welcome students to the MOOCs lecture on Statistical Inference. This is lecture number 12.

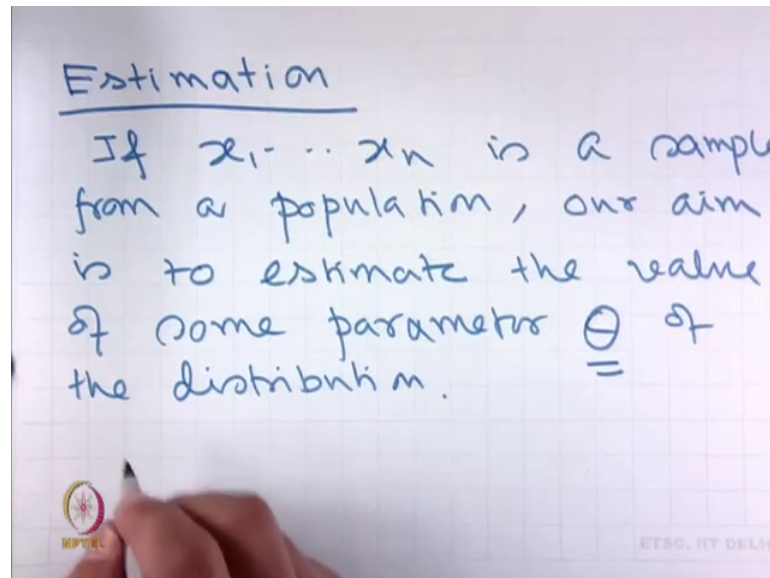

(Refer Slide Time: 00:30)

And today what I will start is called Theory of Estimation. As I told you in my earlier classes that the most important aspect of statistics is statistical inference, to learn about the population parameter with the help of sample statistics. And I have mentioned that there are two basic ways of statistical inference, one is estimation of parameters. Here, the underlying assumption is that the form of the distribution is known, and our job is to identify the parameters of the distribution.

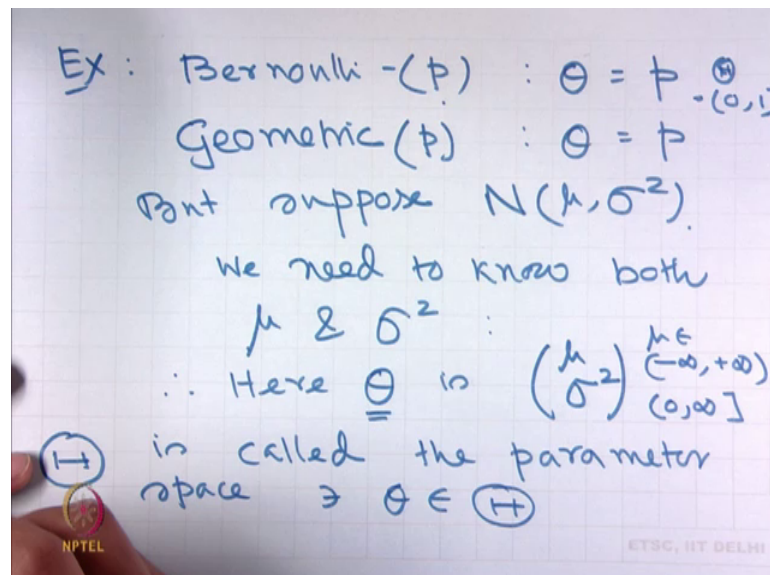

And the other one is testing of hypothesis. Here we want to check whether the sample gives us enough evidence, so that some hypothesis can be accepted. Here, by hypothesis we mean some pre assigned values of the parameters.

(Refer Slide Time: 02:52)

As you can understand now I am going to do on estimation. So, what is an estimator? If x_1 up to x_n is a sample from a population, our aim is to estimate the value of some parameter θ of the distribution. So, what is θ , θ is something, so that if we know the value, we can understand the distribution completely.

(Refer Slide Time: 04:09)

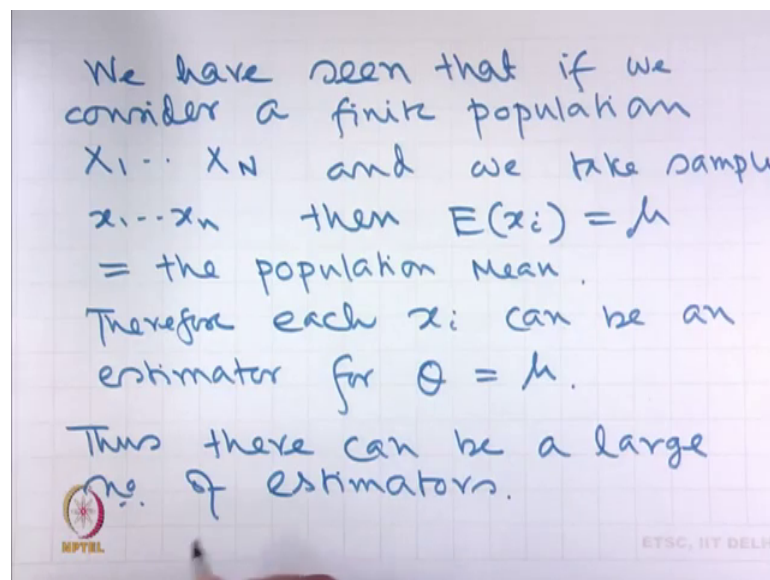

For example, Bernoulli distribution; here P is the only unknown parameter. If we know the value of P , then we know what the distribution is. So, in this case θ is equal to P . Similarly, for geometric here also the parameter is P , therefore θ is equal to P , but

suppose we consider normal μ σ^2 . Here, in order to know the distribution completely we need to know the value of both μ and σ^2 . Therefore, here θ is μ σ^2 or say σ^2 ok, or in other words we are looking at a bivariate parameter. You often find the term capital θ is called the parameter space such that θ can belong to θ .

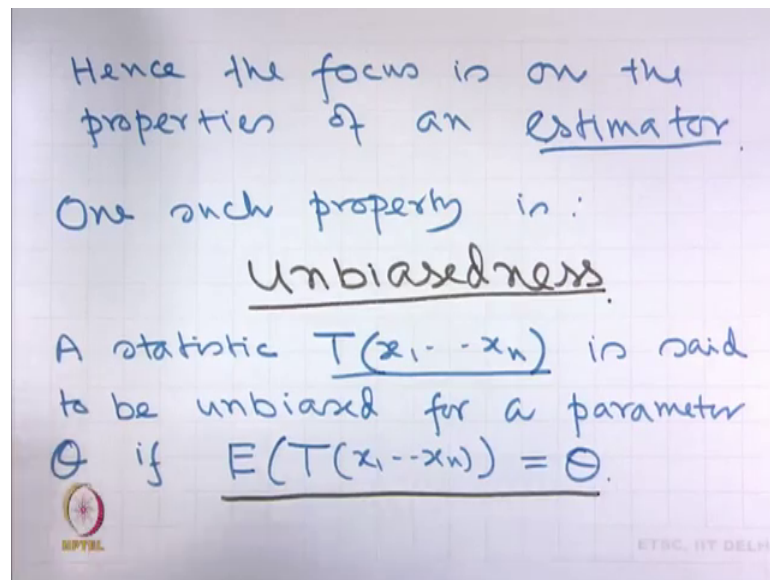

For example, when we are looking at P the capital θ is equal to 0 to 1 on the real line. When we are looking at μ , μ can belong to minus infinity to infinity or on the real line, σ^2 may belong to 0 to infinity on the real line, so that is the parameter space to which that parameter of the distribution can belong to.

(Refer Slide Time: 07:00)

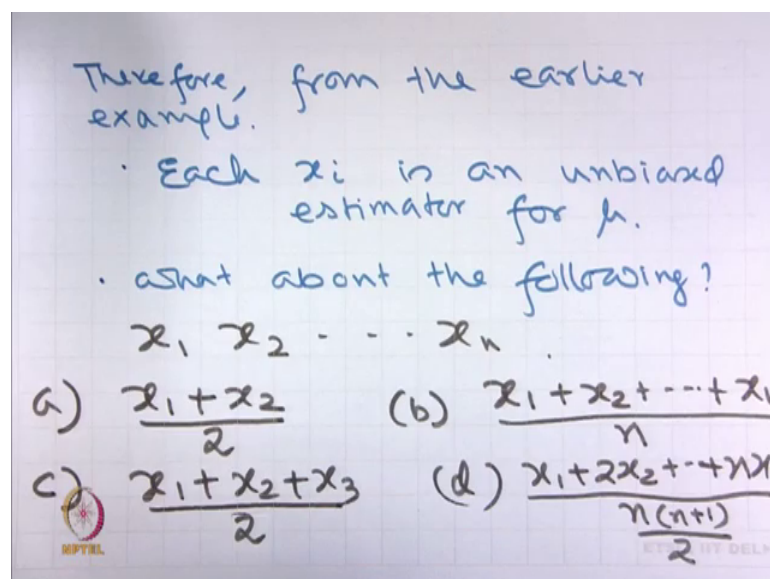

We have already seen some estimators, if you remember; we have seen that, if we consider a finite population X_1, X_2 up to X_N . And we take sample x_1, x_2 up to x_n , then expected value of each x_i is equal to μ is equal to the population mean. Therefore, each x_i can be an estimator for θ is equal to μ . Thus, there can be a large number of estimators. Hence, the question comes, which of the different estimators we should choose for our purpose.

(Refer Slide Time: 08:58)

Hence, the focus is on the properties of an estimator. So, if an estimator satisfies those properties, then we consider it to be better suited for our purpose. One such property is you have already seen unbiasedness. A statistic $T(x_1, x_2, \dots, x_n)$ what does it mean, it means that I have taken the samples x_1, x_2, \dots, x_n . And T is the function that is defined on the sample. So, once the sample is taken we can compute T . It is said to be unbiased for parameter θ if expected value of $T(x_1, \dots, x_n)$ is equal to θ .

(Refer Slide Time: 11:17)

Therefore, from my earlier example each x_i is an unbiased estimator for μ . What about the following I have the sample x_1, x_2, \dots, x_n . So let me consider, a) x_1 plus x_2 by 2. b) x_1 plus x_2 plus x_n by n . c) x_1 plus x_2 plus x_3 by 2. d) x_1 plus $2x_2$ plus n times x_n by n into n plus 1 by 2.

(Refer Slide Time: 13:18)

① $E\left(\frac{x_1 + x_2}{2}\right) = \frac{1}{2}(E(x_1) + E(x_2))$
 $= \frac{1}{2}(\mu + \mu) = \mu$
 $\therefore \frac{x_1 + x_2}{2}$ is unbiased for μ .

② $\frac{x_1 + x_2 + \dots + x_n}{n} = \text{Sample Mean}$
 $E\left(\frac{x_1 + \dots + x_n}{n}\right) = \frac{1}{n}(E(x_1) + \dots + E(x_n))$
 $= \frac{1}{n}(n\mu) = \mu$
 Sample Mean is also an unbiased estimator for μ .

Let us see their expectations, expected value of x_1 plus x_2 by 2, because of the linearity is equal to half of expected value of x_1 plus expected value of x_2 is equal to half times μ plus μ is equal to μ . Therefore, x_1 plus x_2 by 2 is unbiased for μ . 2, x_1 plus x_2 plus x_n by n or in other words we are looking at sample mean. Its expectation is equal to 1 by n times, expectation of x_1 plus up to expectation of x_n is equal to 1 by n times n times μ is equal to μ . Therefore, sample mean is also an unbiased estimator for μ .

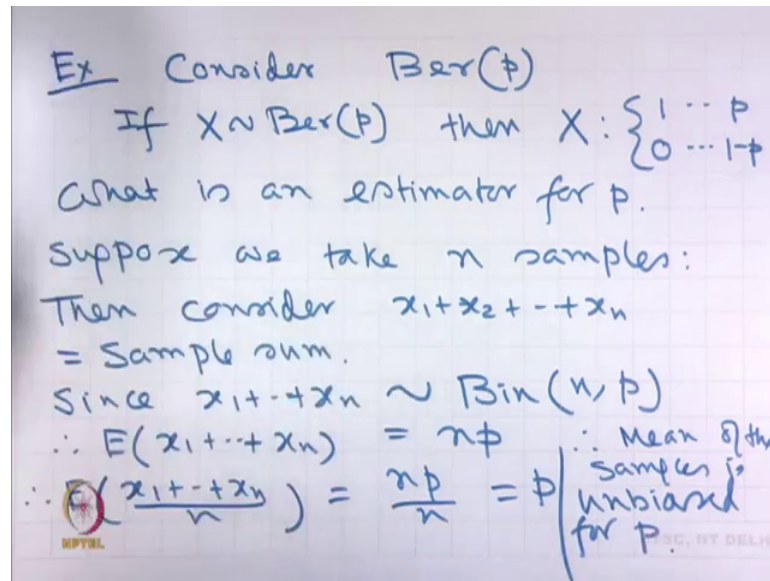

(Refer Slide Time: 15:22)

(3) $E\left(\frac{x_1 + x_2 + x_3}{2}\right) = \frac{1}{2}(\mu + \mu + \mu)$
 $= \frac{3}{2}\mu.$
 $\therefore \frac{x_1 + x_2 + x_3}{2}$ is NOT unbiased for $\mu.$

(4) $E\left(\frac{x_1 + 2x_2 + 3x_3 + \dots + nx_n}{n(n+1)}\right)$
 $= \frac{1}{n(n+1)}(\mu + 2\mu + \dots + n\mu) = \frac{\mu}{n(n+1)}(1 + 2 + \dots + n)$
 $\therefore E\left(\frac{x_1 + 2x_2 + \dots + nx_n}{n(n+1)}\right) = \mu$

X_1 plus x_2 plus x_3 by 2 you can now easily understand that its expectation is equal to half into μ plus μ plus μ is equal to 3 by 2 μ . Therefore, x_1 plus x_2 plus x_3 by 2 is not unbiased for μ . Number 4, x_1 plus 2 x_2 plus 3 x_3 up to $n \times n$ divided by n into n plus 1 by 2. Its expectation is equal to 1 upon n into n plus 1 by 2 multiplied by μ plus 2 μ plus $n \mu$ is equal to μ n into n plus 1 by 2 into 1 plus 2 plus n . And we know that the sum of first n natural numbers is n into n plus 1 by 2, therefore this cancels with this. Therefore, the expectation of x_1 plus 2 x_2 up to $n \times n$ upon n into n plus 1 by 2 is equal to μ . Therefore, this is also an unbiased estimator for the population mean μ .

(Refer Slide Time: 17:38)

Another example consider Bernoulli P what is a Bernoulli distribution we know that. If I toss a coin, then P is the probability of head or mathematically. If x follows Bernoulli of P , then x can take two values 1 with probability P and 0 with probability $1 - P$. What is an estimator for P . Suppose, we take n samples, then consider $x_1 + x_2 + \dots + x_n$ is equal to sample sum.

We know that $x_1 + x_2 + \dots + x_n$ is distributed as binomial with n comma. Therefore, expected value of $x_1 + \dots + x_n$ is equal to nP . Therefore, expected value of $x_1 + x_2 + \dots + x_n$ by n is equal to nP by n is equal to P . Therefore, mean of the samples is unbiased for P . Let me, warn you on a point.

(Refer Slide Time: 20:23)

Note: Unbiasedness does not mean that the obtained value will be equal to the parameter θ .

Ex Suppose we toss a coin n times, and we obtain the sample mean after each toss

consider: $n =$	1	2	3	4	5	6
Outcome = x_i	1	0	0	1	1	0
\bar{x}	1	0.5	$\frac{1}{3}$	0.5	$\frac{3}{5}$	$\frac{1}{2}$
$E(\bar{x}) =$	p .					

 ETSC, IIT DELHI

Unbiasedness does not mean that the obtained value will be equal to the parameter θ . Example suppose, we toss a coin n times, and we obtain the sample mean after each toss. So, consider n is equal to say 1, 2, 3, 4, 5, 6. Suppose, I am looking at 6 tosses, and outcomes are that is x_i are say 1, 0, 0, 1, 1, 0. Therefore, \bar{x} is equal to 1, because it is the mean of one sample it is 0.5 at this point, at this point it is 1 by 3, at this point it is again 0.5 or half, at this point it is 3 by 5, at this point it is again half.

So, depending upon how many tosses you have actually done, the obtained value of the statistic can change. It is not mandatory that they will be equal to the actual value of the parameter, but what we are saying is that, if we consider its expectation, that is going to be equal to P . I hope the distinction is clear.

(Refer Slide Time: 23:31)

We have also seen that
if $\theta = \sigma^2$ = population variance
then sample variance
 $s^2 = \frac{1}{n} \sum (x_i - \bar{x})^2$
is NOT unbiased for σ^2
But $S^2 = \frac{1}{n-1} \sum (x_i - \bar{x})^2$
is unbiased for σ^2 .

We have also seen that, if theta is equal to sigma square is equal to population variance, then sample variance a square is equal to 1 by n sigma x i minus x bar whole square is not unbiased for sigma square. But, S square is equal to 1 upon n minus 1 sigma x i minus x bar whole square is unbiased for sigma square. Therefore, given a parameter, if we want to estimate it, we can get many different statistic. Such that each of them is an unbiased estimator for the population parameter under consideration, which we generally denote as theta.

(Refer Slide Time: 25:24)

The question is which of the
different estimators we should choose.
An important property here is:
Consistency
Def: An estimator $T(x_1, \dots, x_n)$
is said to be consistent for
estimating θ if:
 $P(|T(x_1, \dots, x_n) - \theta| < \epsilon) > 1 - \gamma$
 $\forall n \geq n_0$ for given ϵ & $\gamma > 0$
However small they are.

Therefore, the question is, which of the different estimators we should choose. An important property here is consistency definition, an estimator $T(x_1, x_2, \dots, x_n)$ is said to be consistent for estimating θ . If probability $P(|T(x_1, x_2, \dots, x_n) - \theta| < \epsilon) > 1 - \eta$ for all $n \geq n_0$ for given ϵ , and $\eta > 0$, however small they are. Let us, understand what it means.

(Refer Slide Time: 28:08)

We are given two positive quantities ϵ & η . — both can be very small but > 0 .

$$P(|T(x_1, \dots, x_n) - \theta| < \epsilon) > 1 - \eta$$

$\forall n \geq n_0$

This n_0 depends upon ϵ & η .

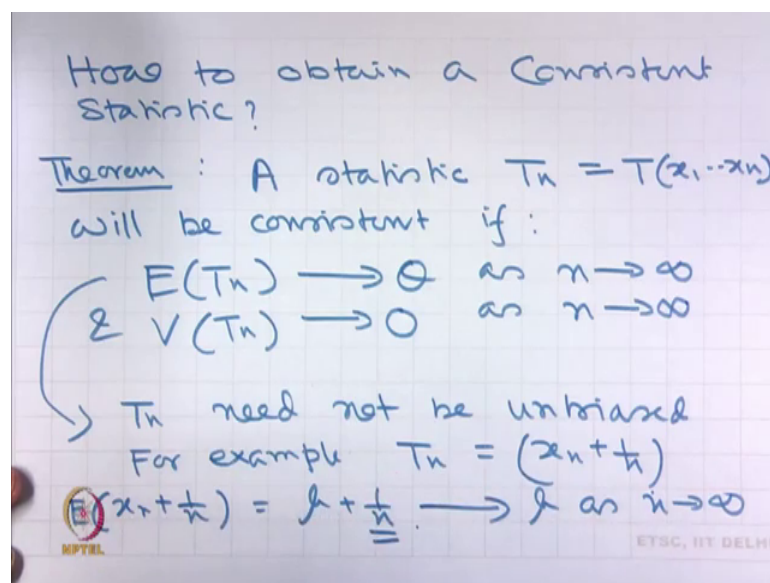

We are given two positive quantities epsilon and eta. They can be very very small, but greater than 0. So, the definition says, that probability P of x_1, x_2, \dots, x_n the obtained value of the statistic from the sample of size n minus θ less than ϵ . So, this is the event. We have the n samples, we have calculated the statistic, and we are saying that, this statistic should be very close to the actual value of the parameter. How much close that, the absolute difference between them is less than ϵ that, probability can be made arbitrarily large that is that is greater than equal to $1 - \eta$, for all n greater than n_0 .

So, what it means suppose this is the actual parameter θ . And we have given an ϵ bound around it. And we are saying that, if we keep on taking the samples, then there will be an integer n_0 . Such that if the sample size is greater than n_0 , then the probability that the obtained value of the statistic will remain within this interval, that probability is going to be arbitrarily large that is it can be made as large as

you want that is it is greater than 1 minus eta that, and eta can be, however small you want.

Obviously, this n naught depends upon both epsilon, and eta. It is not mandatory that the same n naught will work for all values of epsilon and eta, but given epsilon and eta we can choose an n naught, or we can find an n naught. Such that, if the number of samples is more than n naught, then the probability that this sample mean, sample statistic will be very close to the parameter that probability is going to be very very high.

(Refer Slide Time: 31:46)

The question is, how do we obtain a consistent statistic? So, I give you a theorem. A statistic T_n is equal to T of x_1 up to x_n will be consistent. If expected value of T_n goes to theta, as n goes to infinity, and variance of T_n goes to 0, as n goes to infinity. So, first thing we note that, T_n need not be unbiased.

For example, T_n is equal to x_n plus 1 by n . What is the expected value, is this μ plus 1 by n , and these goes to μ , as n goes to infinity, because this is the bias, this is the quantity by which it is different from the parameter or the intended parameter μ . Therefore, x_n plus 1 by n is not an unbiased estimator for μ for any n , but as n goes to infinity; its expected value converges to μ . Therefore, in order to be consistent unbiasedness is not necessary.

(Refer Slide Time: 34:35)

$V(T_n) \rightarrow 0$ as $n \rightarrow \infty$

If $E(T_n) \rightarrow \mu$.

The above two conditions are sufficient for consistency.

If each T_n is unbiased, then the sufficient condition for consistency is $V(T_n) \rightarrow 0$ as $n \rightarrow \infty$

But, we have to also look at that variance of T_n should go to 0, as n goes to infinity. We know that, variance gives us the measure of dispersion. So, if expected value of T_n converges to the μ , then as if variance of T_n goes to 0, then what we can say that, it is coming within arbitrary closeness of the parameter μ . So, the above is a sufficient condition for consistency. If each T_n is unbiased, then we are even better off. So, we need to check the variants of T_n is going to 0, as n is going to infinity.

(Refer Slide Time: 36:36)

Consider the examples discussed before:

1) $\frac{x_1 + x_2}{2}$

$E(T_n) = \mu$

$V(T_n) = \frac{1}{4}(\sigma^2 + \sigma^2)$

$= \frac{\sigma^2}{2}$

Therefore $V(T_n) \rightarrow 0$ as $n \rightarrow \infty$

$\frac{x_1 + x_n}{2}$

$V(T_n) \rightarrow 0$

Let us now consider, we had x_1 plus x_2 by 2, it is unbiased. And variance of T_n is equal to $\frac{1}{4} \sigma^2$ plus σ^2 is equal to $\frac{5}{4} \sigma^2$. First, you notice that, even if we have chosen samples x_1 up to x_n , we are trying to estimate the parameter on the basis of only the first two samples, actually here we are not using the remaining samples. Therefore, the variance of T_n will not change, even if we take many different samples, it will remain $\frac{5}{4} \sigma^2$. And therefore, variance of T_n does not go to 0, as n goes to infinity.

Suppose, instead of x_1 plus x_2 by 2, I would have chosen x_1 plus x_n by 2. Then, this is also unbiased, also I am taking care of the large sample, that I have taken, but here also variance of T_n will not go to 0. Therefore, neither this, nor this is a consistent estimator of μ in this case.

(Refer Slide Time: 39:01)

Handwritten mathematical derivation on a grid background:

$$2) \frac{x_1 + \dots + x_n}{n} = \bar{x}$$

$$E(\bar{x}) = \mu$$

$$V(\bar{x}) = \frac{\sigma^2}{n} \rightarrow 0$$

$$\therefore \text{as } n \rightarrow \infty \quad V(T_n) = V(\bar{x}) \rightarrow 0$$

$\therefore \bar{x}$ is unbiased & consistent for μ .

Logos for NPTEL and IIT DELHI are visible at the bottom of the slide.

The second example was x_1 plus x_n by x_1 plus x_2 plus x_n by n is equal to \bar{x} . Expected value of \bar{x} is equal to μ . Therefore, the first condition is automatically satisfied. Variance of \bar{x} we know is equal to $\frac{\sigma^2}{n}$. Therefore, as n goes to infinity, variance of T_n , which is nothing but \bar{x} goes to 0, because σ^2 by n σ^2 is fixed, therefore as n increases, this goes to 0. Therefore, by the above theorem, \bar{x} is unbiased, but that is not important, and what is important is that, it is consistent for μ .

(Refer Slide Time: 40:36)

3) $\frac{x_1 + 2x_2 + \dots + nx_n}{\frac{n(n+1)}{2}}$
Its expectation is μ
$$2V(\quad) = \frac{1}{\left(\frac{n(n+1)}{2}\right)^2} (\sigma^2 + 4\sigma^2 + 9\sigma^2 + \dots + n^2\sigma^2)$$
$$= \frac{1}{\left(\frac{n(n+1)}{2}\right)^2} \sigma^2 (1^2 + 2^2 + \dots + n^2)$$
$$= \frac{1}{\left(\frac{n(n+1)}{2}\right)^2} \left(\frac{n(n+1)(2n+1)}{6} \right) \sigma^2$$

Let me consider this also x_1 plus $2x_2$ plus $n x_n$ upon n into n plus 1 by 2 . What is the variance, its expectation is μ , and variance is equal to 1 upon n into n plus 1 by 2 whole square into σ^2 plus 4 σ^2 plus 9 σ^2 plus n square σ^2 is equal to 1 upon n into n plus 1 by 2 whole square multiplied by σ^2 into 1 square plus 2 square plus up to n square is equal to 1 upon n into n plus 1 by 2 whole square into sum of square of first n natural numbers is equal to n into n plus 1 into $2n$ plus 1 by 6 multiplied by σ^2 .

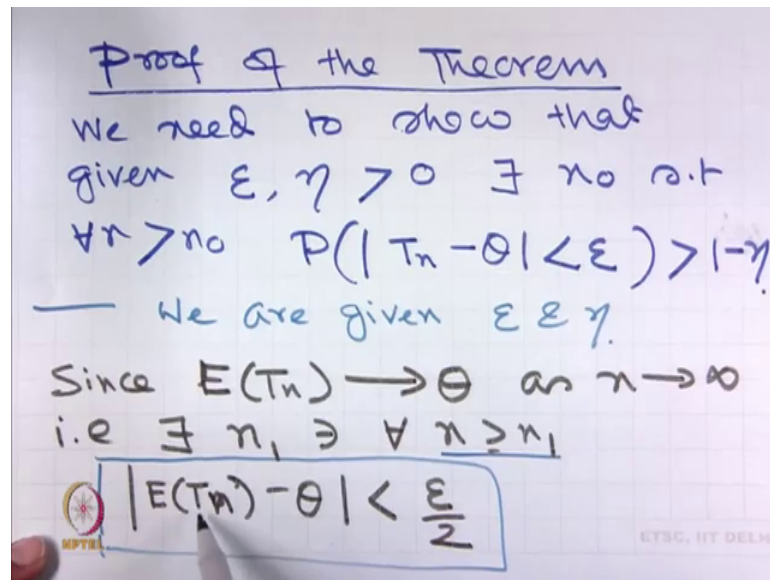

(Refer Slide Time: 42:13)

$$= \frac{4}{6} \frac{n(n+1)(2n+1)}{n^2(n+1)^2} \sigma^2$$
$$= \frac{2}{3} \frac{2n+1}{n(n+1)} \rightarrow 0 \text{ as } n \rightarrow \infty$$

\therefore This is consistent for μ .

Which is equal to $\frac{4}{6n} + \frac{1}{2n} + \frac{1}{n^2}$ into $n + 1$ square. σ^2 is equal to $\frac{2}{3}$ into one of them cancels $\frac{2}{3} + \frac{1}{n} + \frac{1}{n^2}$. Since, the numerator is linear in n , but the denominator is quadratic in n , we know that its limit is 0, as n goes to infinity. Therefore, this is consistent for μ .

(Refer Slide Time: 43:22)

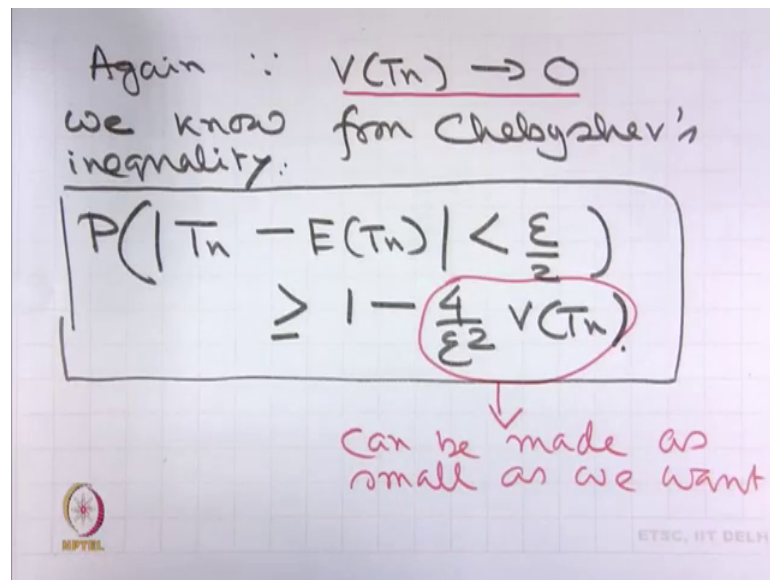

We need to show that, given epsilon and eta greater than 0, there exist n_0 , such that for all n greater than n_0 probability modulus of T_n minus θ less than epsilon is greater than $1 - \eta$. So, this is what we will have to prove, so we are given epsilon and eta. First thing that is given is expected value of T_n converges to θ , as n goes to infinity that means, there exist n_1 such that for all n greater than equal to n_1 modulus of expected value of T_n minus θ less than epsilon by 2. So, we have been given an epsilon, we are trying to identify an n_1 , such that for all n greater than equal to n_1 . This difference expected value of T_n minus θ less than epsilon by 2.

(Refer Slide Time: 45:44)

Again $\because V(T_n) \rightarrow 0$
we know from Chebyshev's inequality:

$$P\left(|T_n - E(T_n)| < \frac{\epsilon}{2}\right) \geq 1 - \frac{4}{\epsilon^2} V(T_n)$$

can be made as small as we want

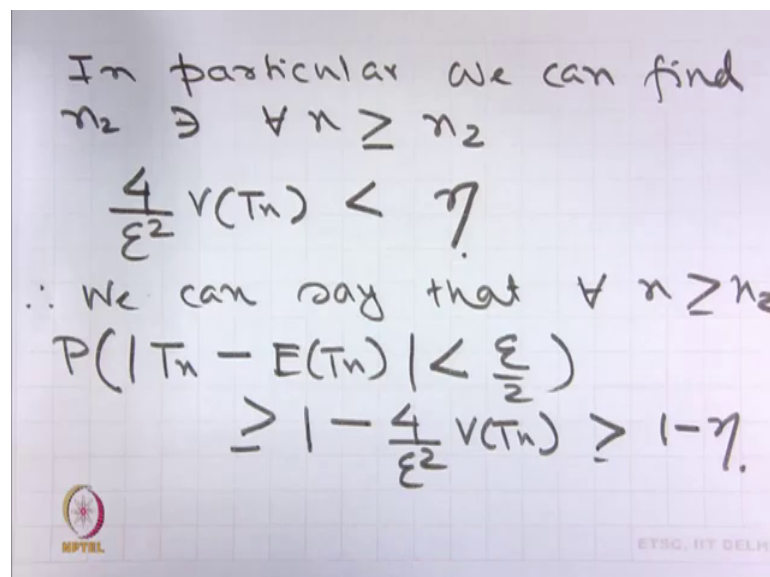

Again, since variance of T_n is going to 0. We know from Chebyshev's inequality, probability modulus of T_n minus expected value of T_n less than epsilon by 2 is greater than equal to 1 minus 4 epsilon square into variance of T_n . This is known because of Chebyshev's inequality. Therefore, what we get it, that as variance of T_n is going to 0. This quantity can be made very very small right.

(Refer Slide Time: 47:35)

In particular we can find $n_2 \ni \forall n \geq n_2$

$$\frac{4}{\epsilon^2} V(T_n) < \eta$$

\therefore We can say that $\forall n \geq n_2$

$$P\left(|T_n - E(T_n)| < \frac{\epsilon}{2}\right) \geq 1 - \frac{4}{\epsilon^2} V(T_n) \geq 1 - \eta$$

In particular, we can choose or we can find n_2 , such that for all n greater than equal to n_2 $\frac{4}{\epsilon^2}$ by epsilon square into variance of T_n is less than eta. This is possible, because **this**

quantity is going to 0, and ϵ is fixed, that is given to us. Therefore, we can say that for all n greater than equal to n_2 . Probability modulus of T_n minus expected value of T_n less than $\epsilon/2$ is greater than equal to $1 - \epsilon/4$ by ϵ^2 into variance of T_n , which is greater than equal to $1 - \epsilon$.

Therefore, what we got, so we have an n_1 , such that for all n greater than equal to n_1 , expected value of T_n minus θ is less than $\epsilon/2$. There is an n_2 , such that for all n greater than equal to n_2 , probability T_n minus expected value of T_n less than $\epsilon/2$ is greater than $1 - \epsilon$.

(Refer Slide Time: 49:33)

We have to find $n_0 \Rightarrow$
 $P(|T_n - \theta| < \epsilon) > 1 - \gamma$
 Let n_0 be $\max(n_1, n_2)$
 $\therefore \forall n \geq n_0$
 $|E(T_n) - \theta| < \frac{\epsilon}{2}$
 $P(|T_n - E(T_n)| < \frac{\epsilon}{2}) \geq 1 - \gamma$

Or we have to find n naught, such that probability modulus of T_n minus θ less than ϵ is greater than $1 - \epsilon$. This is what we have to find. Let n naught be maximum of n_1 and n_2 . Therefore, for all n greater than equal to n naught, we have expected value of T_n minus θ is less than $\epsilon/2$, also we have probability modulus of T_n minus expected value of T_n less than $\epsilon/2$ is greater than equal to $1 - \epsilon$.

(Refer Slide Time: 50:48)

$$\begin{aligned}
 & \text{Now } |T_n - \theta| \\
 &= |T_n - E(T_n) + E(T_n) - \theta| \\
 &\leq |T_n - E(T_n)| + |E(T_n) - \theta| \\
 &\frac{P(|T_n - E(T_n)| < \frac{\epsilon}{2})}{\downarrow} < \frac{\epsilon}{2} \quad \forall n \geq n_0 \\
 &> 1 - \eta \quad \forall n \geq n_0 \\
 &P(|T_n - \theta| < \epsilon) > 1 - \eta \quad \forall n \geq n_0
 \end{aligned}$$

Now, modulus of T_n minus θ is equal to modulus of T_n minus expected value of T_n plus expected value of T_n minus θ , which is less than equal to modulus of T_n minus expected value of T_n plus modulus of expected value of T_n minus θ . This is less than $\epsilon/2$ for all n greater than equal to n_0 . This probability less than $\epsilon/2$ is greater than $1 - \eta$ for all n greater than equal to n_0 .

Therefore, from these two, we can see that probability modulus of T_n minus θ less than ϵ is greater than $1 - \eta$ for all n greater than equal to n_0 . So, these proves the sufficiency of the condition that expected value of T_n has to go to θ , and variance of T_n has to go to 0, as n goes to infinity. Then the T_n is going to be a consistent estimator for the parameter θ .

(Refer Slide Time: 52:50)

Suppose a coin is tossed n times.
We have seen that $T_n = \frac{x_1 + \dots + x_n}{n}$ is unbiased for p .

$$\begin{aligned} V(T_n) &= \frac{1}{n^2} V(x_1 + \dots + x_n) \\ &= \frac{1}{n^2} npq \\ &= \frac{pq}{n} \rightarrow 0 \text{ as } n \rightarrow \infty \end{aligned}$$

NPTEL ETSC, IIT DELHI

Suppose, a coin is tossed n times, we have seen T_n is equal to x_1 plus x_2 plus x_3 plus x_4 plus x_5 plus x_6 plus x_7 plus x_8 plus x_9 plus x_{10} plus x_{11} plus x_{12} plus x_{13} plus x_{14} plus x_{15} plus x_{16} plus x_{17} plus x_{18} plus x_{19} plus x_{20} plus x_{21} plus x_{22} plus x_{23} plus x_{24} plus x_{25} plus x_{26} plus x_{27} plus x_{28} plus x_{29} plus x_{30} plus x_{31} plus x_{32} plus x_{33} plus x_{34} plus x_{35} plus x_{36} plus x_{37} plus x_{38} plus x_{39} plus x_{40} plus x_{41} plus x_{42} plus x_{43} plus x_{44} plus x_{45} plus x_{46} plus x_{47} plus x_{48} plus x_{49} plus x_{50} plus x_{51} plus x_{52} plus x_{53} plus x_{54} plus x_{55} plus x_{56} plus x_{57} plus x_{58} plus x_{59} plus x_{60} plus x_{61} plus x_{62} plus x_{63} plus x_{64} plus x_{65} plus x_{66} plus x_{67} plus x_{68} plus x_{69} plus x_{70} plus x_{71} plus x_{72} plus x_{73} plus x_{74} plus x_{75} plus x_{76} plus x_{77} plus x_{78} plus x_{79} plus x_{80} plus x_{81} plus x_{82} plus x_{83} plus x_{84} plus x_{85} plus x_{86} plus x_{87} plus x_{88} plus x_{89} plus x_{90} plus x_{91} plus x_{92} plus x_{93} plus x_{94} plus x_{95} plus x_{96} plus x_{97} plus x_{98} plus x_{99} plus x_{100} by n is unbiased for p . And variance of T_n is equal to 1 by n square into variance of x_1 plus x_2 plus x_3 plus x_4 plus x_5 plus x_6 plus x_7 plus x_8 plus x_9 plus x_{10} plus x_{11} plus x_{12} plus x_{13} plus x_{14} plus x_{15} plus x_{16} plus x_{17} plus x_{18} plus x_{19} plus x_{20} plus x_{21} plus x_{22} plus x_{23} plus x_{24} plus x_{25} plus x_{26} plus x_{27} plus x_{28} plus x_{29} plus x_{30} plus x_{31} plus x_{32} plus x_{33} plus x_{34} plus x_{35} plus x_{36} plus x_{37} plus x_{38} plus x_{39} plus x_{40} plus x_{41} plus x_{42} plus x_{43} plus x_{44} plus x_{45} plus x_{46} plus x_{47} plus x_{48} plus x_{49} plus x_{50} plus x_{51} plus x_{52} plus x_{53} plus x_{54} plus x_{55} plus x_{56} plus x_{57} plus x_{58} plus x_{59} plus x_{60} plus x_{61} plus x_{62} plus x_{63} plus x_{64} plus x_{65} plus x_{66} plus x_{67} plus x_{68} plus x_{69} plus x_{70} plus x_{71} plus x_{72} plus x_{73} plus x_{74} plus x_{75} plus x_{76} plus x_{77} plus x_{78} plus x_{79} plus x_{80} plus x_{81} plus x_{82} plus x_{83} plus x_{84} plus x_{85} plus x_{86} plus x_{87} plus x_{88} plus x_{89} plus x_{90} plus x_{91} plus x_{92} plus x_{93} plus x_{94} plus x_{95} plus x_{96} plus x_{97} plus x_{98} plus x_{99} plus x_{100} is equal to 1 by n square into $n p q$. This we know, because it is a binomial random variable, its variance has to be n by $n p q$, therefore this is equal to $p q$ by n . Therefore, this goes to 0 , as n goes to infinity. Therefore, this sample mean is not only unbiased, it is consistent for estimating p .

Ok students, I stop here. In the next class, I shall examine some more properties of an estimator.

Thank you.
