Lecture – 14
Statistical Inference

(Refer Slide Time: 00:42)

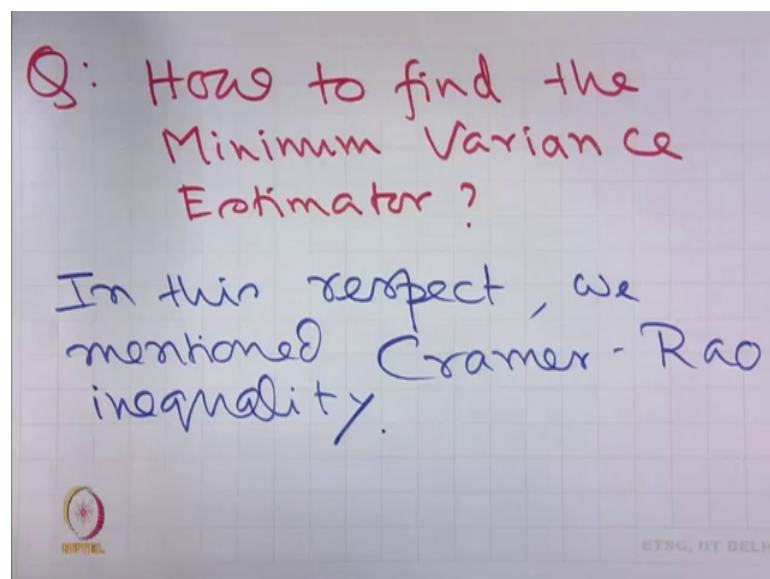

Welcome students to the MOOCs series of lectures on Statistical Inference. This is lecture number 14. In the last two lectures, we have been discussing the properties of an estimator. In particular we have seen two properties, unbiasedness and of course consistency. Towards the end of the last class, I was discussing what is called efficiency. An estimator having the minimum variance; that is, among all possible estimators. If the variance is minimum, then it is called the most efficient estimator.

(Refer Slide Time: 02:10)

In fact, if T_e is the most efficient estimator, then variance then the efficiency of another estimator is defined as variance of T_e divided by variance of T . So, let me call it T . In other words, if T is any estimator, then its efficiency is measured by comparing its variance with the minimum variance estimator. Obviously, this is less than equal to 1, it is one. If we are looking at some estimator T , whose variance is equal to T , variance of whose variance is equal to the variance of T_e . Otherwise, it is more than the variance of T , and therefore this value has to be less than 1.

(Refer Slide Time: 03:57)

The question is how to find the minimum variance estimator, this is very important. As there is no (Refer Time: 04:30) of estimators right. We have already seen that, there can be any number of estimator for estimating a particular parameter theta. But, the problem is how do we know, ~~this~~ This is going to be the minimum variance.

The advantage there by is that, if we know that the minimum variance has to be a some particular value say v , and if we get an estimator T whose variance is same as v , then we know that it is the minimum variance estimator. In this respect, we mentioned Cramer-Rao inequality. This is not for all the classes of estimators. This is applicable to a restricted class of estimator, but still it is very very useful for statistical inference.

(Refer Slide Time: 05:46)

C-R inequality:

If T is an unbiased estimator for θ , then

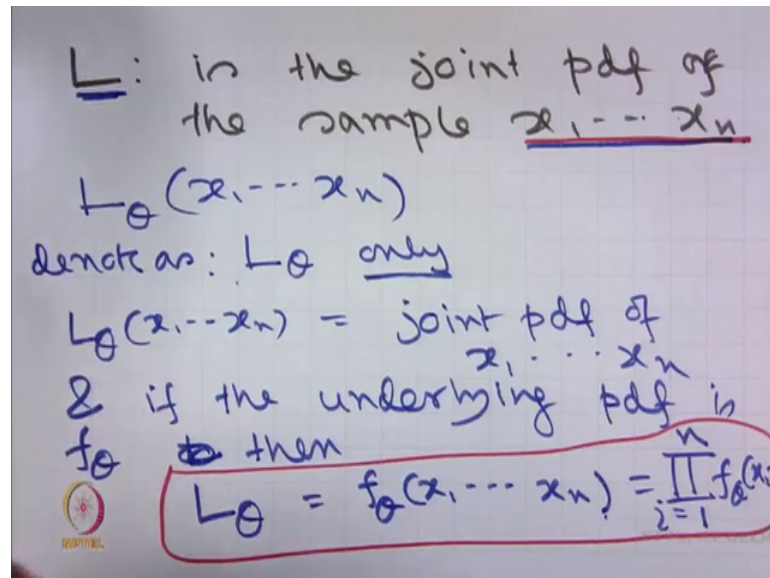

$$V(T) \geq \frac{1}{E\left(\frac{\partial}{\partial \theta} \log L\right)^2}$$

more generally

If T is unbiased for $g(\theta)$ then $V(T) \geq \frac{(g'(\theta))^2}{E\left(\frac{\partial}{\partial \theta} \log L\right)^2}$

The C-R inequality or Cramer-Rao inequality, it states that if T is an unbiased estimator, so this is very important. We are looking at within the class of unbiased estimators for theta, then variance of T is greater than or equal to 1 upon expected value of del del theta log of L whole square. More generally, if T is unbiased for g theta, which is a function of the parameter theta, and we want to estimate g theta, then variance of T is greater than or equal to g prime theta square upon the same quantity, which is expected value of del del theta log L whole square.

(Refer Slide Time: 07:33)

L: is the joint pdf of the sample x_1, \dots, x_n

$L_\theta(x_1, \dots, x_n)$
denote as: L_θ only

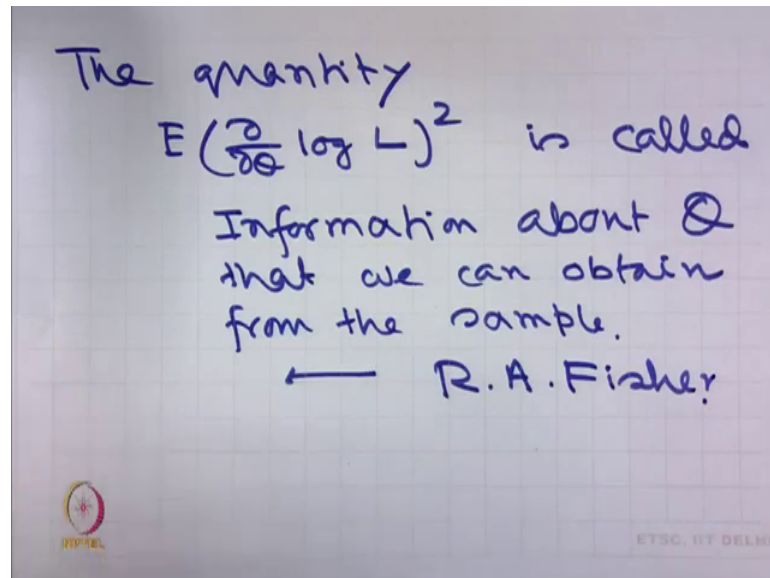

$L_\theta(x_1, \dots, x_n)$ = joint pdf of x_1, \dots, x_n
& if the underlying pdf is f_θ then

$L_\theta = f_\theta(x_1, \dots, x_n) = \prod_{i=1}^n f_\theta(x_i)$

In this respect, what is L, L is the joint pdf of the sample x_1, x_2, x_n or in other words we want to estimate theta or some function of it. We have taken a sample x_1, x_2, x_n , we are looking at that joint density function of x_1, x_2, x_n , which we call L. Of course, L depends upon theta. So, in some books you may find, find $L_\theta(x_1, x_2, x_n)$. In this case, sometimes I will be using L_θ only, because it is understood that, it is based upon the sample x_1, x_2, x_n .

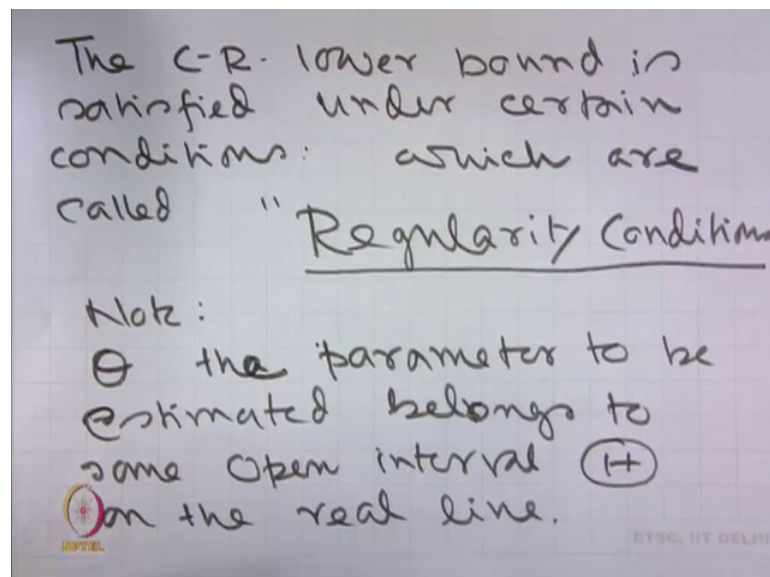

Now, what is L_θ or L_θ of x_1, x_2, x_n , it is joint pdf of x_1, x_2, x_n . And if the underlying pdf is f_θ , because this is the pdf that involves theta, then L_θ is equal to f_θ of x_1, x_2, x_n . And if they are independent, then we can write it as product of f_θ of x_i , i is equal to 1 to n . So, do not get confused with this L_θ , it is something that we know very well. Since, the samples are independent most of them will be assuming, this form that L_θ is equal to the product of the individual density of the sample x_1, x_2 , and x_n .

(Refer Slide Time: 10:11)

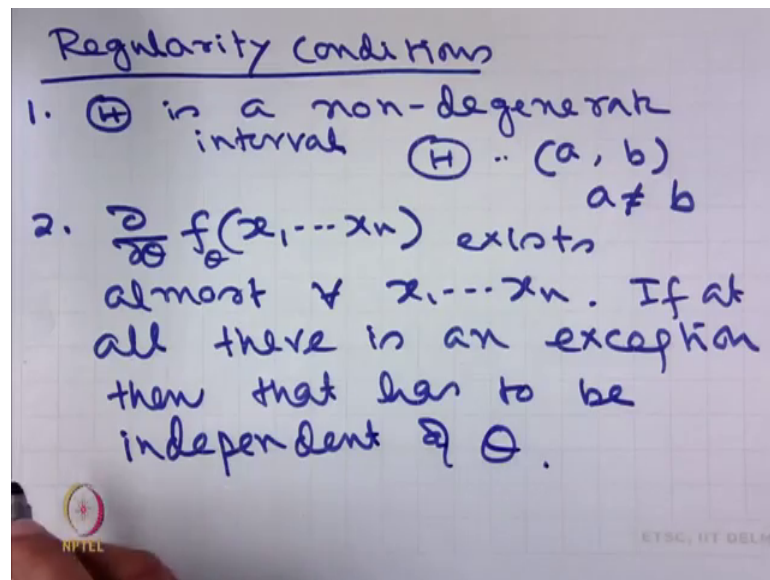

The quantity expected value of del del theta of log L whole square is called the information about theta, that we can obtain from the sample. And this name is being given by R. A. Fisher ok.

(Refer Slide Time: 11:12)

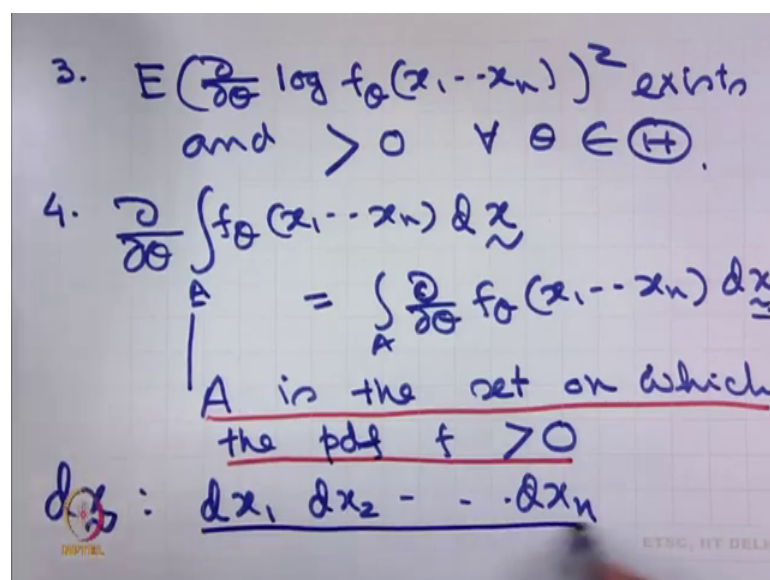

Now, as I mentioned earlier that the Cramer-Rao lower bound is satisfied under certain conditions which are called regularity conditions. Note that θ the parameter to be estimated belongs to some open interval θ on the real line.

(Refer Slide Time: 12:47)

Theta is a non-degenerate interval that means, theta has to be of the form a to b, a not equal to b, so that differentiation with respect to theta make sense. The derivative of the likelihood function exists almost for all x_1, x_2, x_n . If at all there is an exception that means, if it does not exist on some interval, if there exists such an interval, then that has to be independent of theta.

(Refer Slide Time: 14:55)

3, expected value of del del theta log of f theta of x_1, x_2, x_n whole square exists and greater than 0 for all theta belonging to theta, because we know in the Cramer- Rao

bound this comes in the denominator. So, if it is not defined or if it is equal to 0, then that term is not valid, therefore this has to be one of the constraints. $\frac{\partial}{\partial \theta} \int f_{\theta}(x_1, x_2, \dots, x_n) dx$ is equal to $\int \frac{\partial}{\partial \theta} f_{\theta}(x_1, x_2, \dots, x_n) dx$.

Now, you may ask what is this notation, and what is A. So, A is the set on which the pdf f is greater than 0 or in other words we are looking at only the region on which the probability density function is greater than 0. And what is dx, it is basically dx_1, dx_2, \dots, dx_n . Say for example, here I am integrating $f_{\theta}(x_1, x_2, \dots, x_n)$ and to be mathematically precise, I have to integrate it with respect to x_1 , then with respect to x_2 and with respect to x_n . So, it is basically invariable integration. To make to keep it notational is simpler,simpler: I am using that notation dx with a tilde, which actually means this quantity.

(Refer Slide Time: 17:53)

$$5) \frac{\partial}{\partial \theta} \int T f_{\theta}(x_1, \dots, x_n) dx$$

$$= \int_A \frac{\partial}{\partial \theta} T f_{\theta}(x_1, \dots, x_n) dx$$

And number 5 is $\frac{\partial}{\partial \theta} \int T f_{\theta}(x_1, x_2, \dots, x_n) dx$ is equal to integration of so if you look at 4 and 5, you can see that basically we are allowing the differentiation to moved into the integral sign. And this is possible, if this limit of integration,integration does not depend upon theta ok.

(Refer Slide Time: 19:05)

Pf: $V(T) \geq \frac{(g'(\theta))^2}{E\left(\frac{\partial}{\partial \theta} \log f_{\theta}(x_1, \dots, x_n)\right)^2}$

Note: Here log in wrt e.

- T is unbiased for $g(\theta)$.

With this assumption, now let us prove the Cramer-Rao bound that is proof that variance of T is greater than equal to g prime theta whole square upon expected value of del del theta log f theta of x 1, x 2, x n whole square. Note, here logarithm is with respect to e and also note T is unbiased for g theta ok. So, we begin the proof in the following way.

(Refer Slide Time: 20:05)

(A) We know

$$\int_A f_{\theta}(x_1, \dots, x_n) dx = 1$$
$$\therefore \frac{\partial}{\partial \theta} \int_A f_{\theta}(x_1, \dots, x_n) dx = 0$$
$$\therefore \int_A \frac{\partial}{\partial \theta} f_{\theta}(x_1, \dots, x_n) dx = 0$$
$$\int_A \frac{\partial}{\partial \theta} L_{\theta} dx = 0 \dots (A)$$

We know, integration over a of f theta x 1, x 2, x n, d x that means, I am looking at the joint density function. And I am integrating it over, the entire possible range, and that has to be equal to 1, because the total probability is 1. Therefore, del del theta over A of f

theta x 1, x 2, x n, d x is equal to now, I am differentiating this with respect to theta, and this is going to be 0. Now, by the regularity condition that differentiation under integration, we can write it as follows or we can write it as so this is the first finding A. I will come back to it later.

(Refer Slide Time: 21:49)

The image shows a handwritten derivation on a whiteboard. It starts with the equation:
$$\text{Now } \int_A \frac{\partial}{\partial \theta} L_{\theta} d\mathbf{x} = 0$$
This is then rewritten as:
$$= \int_A \frac{1}{L_{\theta}} \left(\frac{\partial}{\partial \theta} L_{\theta} \right) L_{\theta} d\mathbf{x} = 0$$
The next step is:
$$= \int_A \frac{\partial}{\partial \theta} (\log L_{\theta}) L_{\theta} d\mathbf{x} = 0$$
An arrow points from the L_{θ} term in the second integral to the definition $L_{\theta}(x_1, \dots, x_n)$. Finally, the result is boxed in red:
$$E\left(\frac{\partial}{\partial \theta} \log L_{\theta}\right) = 0$$

Now, integration of del del theta of L theta d x is equal to 0. So, let me write it as integration of 1 by L theta del del theta L theta into L theta d x is equal to 0. I am dividing and multiplying by L theta, and since I am considering the range, where L theta is greater than 0, this makes sense.

Because, if we differentiate log of L theta with respect to theta and taking that partial derivative, then what we are getting, this is 1 upon L theta into del del theta of log L. So, this entire quantity, I can write it as this. And that we are multiplying by L theta of x 1, x 2, x n and integrating. So, what is this, it is a function of x 1, x 2, x n, because this L theta is L theta of x 1, x 2, x n. Therefore, this whole quantity is nothing but expected value of del del theta of log of L theta. And just now, we observe that this is equal to 0. So, this is our finding 1.

(Refer Slide Time: 24:06)

Again $\because T$ is an unbiased estimator for $g(\theta)$

$$\int_A T \cdot L_{\theta}(x_1, \dots, x_n) dx = g(\theta)$$

$$\therefore \frac{\partial}{\partial \theta} \int_A T L_{\theta} dx = g'(\theta)$$

$$\therefore \int_A \frac{\partial}{\partial \theta} T L_{\theta} dx = g'(\theta)$$

Again since T is an unbiased estimator for g theta, integration over a T of L theta, let me write it with x_1, x_2, \dots, x_n , but as we have seen, I am often leaving out this part. If the notation is understood, dx is equal to g theta, because that is the expectation of T . Now, differentiating it with respect to theta we get, I am leaving out this.

(Refer Slide Time: 25:37).

$$\int_A \frac{\partial}{\partial \theta} T L_{\theta} dx = g'(\theta)$$

$$\propto \int_A T \left(\frac{1}{L_{\theta}} \frac{\partial}{\partial \theta} (L_{\theta}) \right) L_{\theta} = g'(\theta)$$

$$\propto \int_A T \left(\frac{\partial}{\partial \theta} \log L_{\theta} \right) L_{\theta} = g'(\theta)$$

$$\Rightarrow E \left(T \cdot \frac{\partial}{\partial \theta} \log L_{\theta} \right) = g'(\theta)$$

- 2

Now, by regularity condition, we can push it inside or as before, we divide and multiply by L theta. So, I have multiplied and divided by L theta or integration over A del del theta of log of L theta into L theta is equal to g prime theta or this is expected value of T del

del theta log of L theta, this is ~~is~~ equal to g prime theta. So, if you look at in 1, we have got expected value of del del theta log theta is equal to 0. And here, we have got expected value of T into del del theta log theta is equal to g prime theta. Let me call it equation 2.

(Refer Slide Time: 37:32)

We know that:
the correlation coefficient
betⁿ two variables x & y
 $= \rho_{xy}$ in $\exists \rho^2_{xy} \leq 1$
 $\therefore \text{COV}(X, Y) \leq \sqrt{V(X)V(Y)}$
for any two r.v.s
 X & Y

Now, we know that covariance the, we know that the correlation coefficient between two variables X and Y , which we called rho XY is such that rho square XY is less than equal to 1 that is, because the mod value of rho XY has to be less than equal to 1. Now, what is rho? rho is equal to covariance of XY upon root over variance of X and variance of Y . Therefore, covariance of X, Y square is less than equal to variance of X into variance of Y , and this is true for any two random variables X and Y .

(Refer Slide Time: 29:15)

$$\begin{aligned} \therefore \text{Cov}(T, \frac{\partial}{\partial \theta} \log L_{\theta})^2 &\leq \\ &V(T) \cdot V(\frac{\partial}{\partial \theta} \log L_{\theta}) \quad \text{--- (3)} \\ \text{Now} \cdot \\ \text{Cov}(T, \frac{\partial}{\partial \theta} \log L_{\theta}) &= E(T \cdot \frac{\partial}{\partial \theta} \log L_{\theta}) \\ &\quad - \underbrace{E(T) \cdot E(\frac{\partial}{\partial \theta} \log L_{\theta})}_{=0} \end{aligned}$$

Therefore, we can write that covariance between T and $\frac{\partial}{\partial \theta} \log L_{\theta}$ is less than equal to variance of T into variance of $\frac{\partial}{\partial \theta} \log L_{\theta}$ square. Now, covariance between T and $\frac{\partial}{\partial \theta} \log L_{\theta}$ can be written as expected value of T times $\frac{\partial}{\partial \theta} \log L_{\theta}$ minus expected value of T into expected value of $\frac{\partial}{\partial \theta} \log L_{\theta}$. This as we have seen is equal to 0, therefore this quantity is 0.

(Refer Slide Time: 30:47)

$$\begin{aligned} \therefore \text{Cov}(T, \frac{\partial}{\partial \theta} \log L_{\theta}) &= E(T \cdot \frac{\partial}{\partial \theta} \log L_{\theta}) \\ &= g'(\theta) \\ \therefore \text{From (3)} \\ (g'(\theta))^2 &\leq V(T) V(\frac{\partial}{\partial \theta} \log L_{\theta}) \\ \text{or } V(T) &\geq \frac{(g'(\theta))^2}{V(\frac{\partial}{\partial \theta} \log L_{\theta})} \quad \text{(4)} \end{aligned}$$

Therefore, we are left with covariance between T and $\frac{\partial}{\partial \theta} \log L_{\theta}$ is equal to expected value of $T \frac{\partial}{\partial \theta} \log L_{\theta}$, and which we have found that expected

value of $T \frac{\partial}{\partial \theta} \log L \theta$ is equal to $g' \theta$. Therefore, this is equal to $g' \theta$.

Now, let us look at this, let me call it 3. Therefore, by putting the value $g' \theta$ here, we get $g' \theta^2$ is less than equal to variance of $T \frac{\partial}{\partial \theta} \log L \theta$ or variance of T is less than equal to $g' \theta^2$ whole square upon variance of $\frac{\partial}{\partial \theta} \log L \theta$. Let us call it 4 sorry I made a mistake there variance of T has to be greater than equal to this quantity.

(Refer Slide Time: 33:10)

$$V\left(\frac{\partial}{\partial \theta} \log L \theta\right) = E\left(\frac{\partial}{\partial \theta} \log L \theta\right)^2 - \left(E\left(\frac{\partial}{\partial \theta} \log L \theta\right)\right)^2$$

$$\therefore V\left(\frac{\partial}{\partial \theta} \log L \theta\right) = E\left(\frac{\partial}{\partial \theta} \log L \theta\right)^2 = 0 \text{ from } \textcircled{1}$$

Now, in 4 let us look at what is variance of $\frac{\partial}{\partial \theta} \log L \theta$ is equal to expected value of $\frac{\partial}{\partial \theta} \log L \theta$ whole square minus expected value of $\frac{\partial}{\partial \theta} \log L \theta$ square. And this is equal to 0 from 1. Therefore, variance of $\frac{\partial}{\partial \theta} \log L \theta$ is equal to expected value of $\frac{\partial}{\partial \theta} \log L \theta$ whole square, putting this in 4.

(Refer Slide Time: 34:11)

\therefore From (4)

$$\underline{V(T)} \geq \frac{(g'(\theta))^2}{E\left(\frac{\partial}{\partial \theta} \log L_{\theta}\right)^2}$$

QED

$I(\theta)$

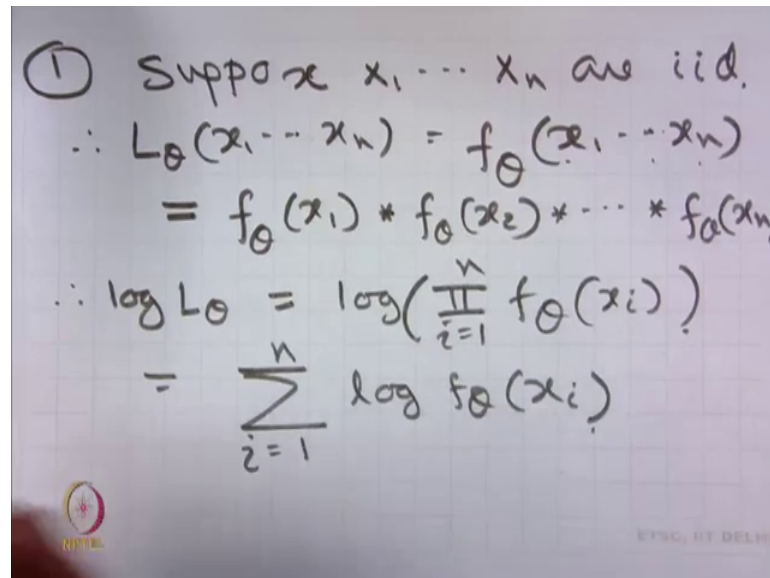

From 4, which is variance of T is greater than equal to g prime θ whole square upon variance of $\frac{\partial}{\partial \theta} \log L_{\theta}$, we can write it as variance of T is greater than equal to g prime θ whole square upon expected value of $\frac{\partial}{\partial \theta} \log L_{\theta}$ whole square. So, this is the result, that we were trying to prove that variance of T has to be greater than equal to this, where this is called the $I(\theta)$.

(Refer Slide Time: 35:14).

This quantity $E\left(\frac{\partial}{\partial \theta} \log L_{\theta}\right)^2$ is often difficult to calculate. Hence I give some simpler form.

Now, this quantity expected value of $\frac{\partial}{\partial \theta} \log L_{\theta}$ whole square is often difficult to calculate. Hence, I give some simpler form.

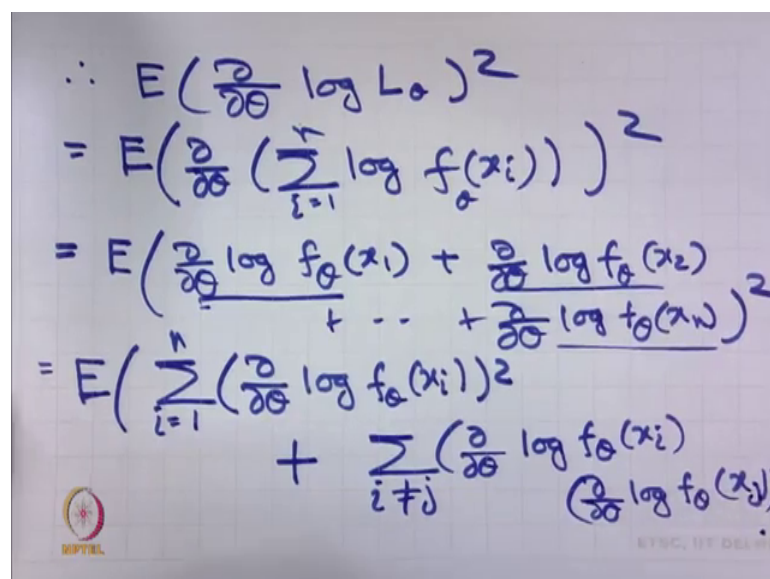

(Refer Slide Time: 35:57)

① Suppose x_1, \dots, x_n are iid.
 $\therefore L_\theta(x_1, \dots, x_n) = f_\theta(x_1, \dots, x_n)$
 $= f_\theta(x_1) * f_\theta(x_2) * \dots * f_\theta(x_n)$
 $\therefore \log L_\theta = \log\left(\prod_{i=1}^n f_\theta(x_i)\right)$
 $= \sum_{i=1}^n \log f_\theta(x_i)$

Suppose x_1, x_2, x_n are i i d that means, they are independent and identically distributed. Therefore, what is L_θ of x_1, x_2, x_n this is is equal to f_θ of x_1, x_2, x_n , which is the joint pdf of the sample values. Since, these are independent, we can write this as f_θ of x_1 into f_θ of x_2 into f_θ of x_n . Therefore, log of L_θ is equal to log of the product. And since log of product is equal to some of the logs, this is same as sigma, i is equal to 1 to n log of $f_\theta x_i$.

(Refer Slide Time: 37:32)

$\therefore E\left(\frac{\partial}{\partial \theta} \log L_\theta\right)^2$
 $= E\left(\frac{\partial}{\partial \theta} \left(\sum_{i=1}^n \log f_\theta(x_i)\right)\right)^2$
 $= E\left(\frac{\partial}{\partial \theta} \log f_\theta(x_1) + \frac{\partial}{\partial \theta} \log f_\theta(x_2) + \dots + \frac{\partial}{\partial \theta} \log f_\theta(x_n)\right)^2$
 $= E\left(\sum_{i=1}^n \left(\frac{\partial}{\partial \theta} \log f_\theta(x_i)\right)^2 + \sum_{i \neq j} \left(\frac{\partial}{\partial \theta} \log f_\theta(x_i) \frac{\partial}{\partial \theta} \log f_\theta(x_j)\right)\right)$

Therefore, expected value of $\text{del del theta log L theta whole square}$ is equal to expected value of $\text{del del theta of sigma log of f x i, i is equal to 1 to n whole square}$ is equal to expected value of $\text{del del theta of log of f theta x 1 plus del del theta of log of f theta of x 2 plus del del theta of log of f theta of x n whole square}$. So, now you will understand the difficulty, it becomes the sum of n terms whole square.

So, this we are writing as expected value of $\text{sigma i is equal to 1 to n del del theta of log of f theta of xi whole square}$, because I am collecting the individual square terms plus $\text{sigma over i not equal to j del del theta of log of f theta x i into del del theta of log of f theta x j}$. And I am looking at expectation of that one, bringing the expectation because of the linearity of expectation.

(Refer Slide Time: 39:44).

$$\begin{aligned}
 &= \sum_{i=1}^n E \left(\frac{\partial}{\partial \theta} \log f_{\theta}(x_i) \right)^2 \\
 &\quad + \sum_{i \neq j} E \left(\frac{\partial}{\partial \theta} \log f_{\theta}(x_i) \right) \left(\frac{\partial}{\partial \theta} \log f_{\theta}(x_j) \right) \\
 &= \sum_{i=1}^n E \left(\frac{\partial}{\partial \theta} \log f_{\theta}(x) \right)^2 + 0 \\
 &\therefore E \left(\frac{\partial}{\partial \theta} \log L \right)^2 = n E \left(\frac{\partial}{\partial \theta} \log f(x) \right)^2 \\
 &= I(\theta)
 \end{aligned}$$

$\text{cov}(X, Y) = E(XY) - E(X)E(Y) = 0$

This is is equal to $\text{sigma i is equal to 1 to n expected value of del del theta of log of f theta x i whole square plus sigma i not equal to j expected value of del del theta log of f theta of x i into del del theta of log of f theta of x j, i not equal to j}$. Now, note that all x i's are identically distributed. Therefore, this term is same for all i. Therefore, this particular term boils down to $\text{sigma i is equal to 1 to n expected value of del del theta of log of f theta of x square}$ plus let us consider this part it is the expected value of two terms, the product of two terms, one is based on x i, other is based on x j. And x i and x j are independent.

Therefore, the covariance between them is has to be 0, and also we have seen that expected value of this is 0, because even for that greater thing the L we have found that expected value of $\frac{\partial}{\partial \theta} \log L$ is equal to 0 by the same technique. We can find out that expectation of $\frac{\partial}{\partial \theta} \log f(x; \theta)$ is equal to 0. Therefore, what we find that this is the product of two terms, which are independent.

Therefore, their covariance is $\theta_{,0}$; moreover their individual expectation is 0. And therefore, since covariance of X, Y is equal to expected value of X Y minus expected value of X into expected value of Y. In this case, we find this is 0, this is 0, therefore expected value of X Y is also going to be 0 or in other words expected value of $\frac{\partial}{\partial \theta} \log f(x; \theta)$ multiplied by $\frac{\partial}{\partial \theta} \log f(x; \theta)$. This is going to be 0, for each pair i j, i not equal to j. Therefore, I make it 0. I hope that, you understood the logic.

Therefore, what we find that expected value of $\frac{\partial}{\partial \theta} \log L$ whole square is actually this term, which is nothing but n times expected value of $\frac{\partial}{\partial \theta} \log f(x; \theta)$ square. So, this is another interesting form of I theta, in solving problems instead of using this we may often use. This as the denominator of the right hand side of the lower bound or right hand side of the Cramer- Rao inequality.

(Refer Slide Time: 44:00).

Another Form for $I(\theta)$

$$E\left(\frac{\partial}{\partial \theta} \log L\right) = 0$$

Consider $E\left(\frac{\partial^2}{\partial \theta^2} \log L\right)$

Now, let me discuss another form for I theta. We know that the expected value of $\frac{\partial}{\partial \theta} \log L$ is equal to 0, we have already seen that. Now, consider expected value of let us try to compute this. What is this?

(Refer Slide Time: 44:58).

Consider

$$\frac{\partial}{\partial \theta} \left(\left(\frac{\partial}{\partial \theta} \log L_{\theta} \right) L_{\theta} \right)$$
$$= \frac{\partial}{\partial \theta} \left(\frac{\partial}{\partial \theta} \log L_{\theta} \right) \cdot L_{\theta} + \left(\frac{\partial}{\partial \theta} \log L_{\theta} \right) \left(\frac{\partial}{\partial \theta} L_{\theta} \right)$$
$$= \left(\frac{\partial^2}{\partial \theta^2} \log L_{\theta} \right) L_{\theta} + \left(\frac{\partial}{\partial \theta} \log L_{\theta} \right) \left(\frac{\partial}{\partial \theta} L_{\theta} \right)$$

Let us consider, the product del del theta log L and L. And let us consider, it is partial derivative with respect to theta, we know that these are also dependent on theta. By by rule of multiplication for derivatives, we can write it as del del theta of del del theta log L theta times L theta plus del del theta log L theta into all right.

This is very straightforward, because it is first function derivative of 1st function into 2nd function plus 1st function into derivative of 2nd function. This we can write as del 2 del square del theta square of this we can write as del square del theta square of log L theta times L theta plus del del theta of log L theta times del del theta of L theta.

(Refer Slide Time: 47:13)

$$\begin{aligned}
 & \therefore \left(\frac{\partial^2}{\partial \theta^2} \log L_\theta \right) L_\theta \\
 &= \frac{\partial}{\partial \theta} \left(\frac{\partial}{\partial \theta} \log L_\theta \right) L_\theta \\
 &\quad - \left(\frac{\partial}{\partial \theta} \log L_\theta \right) \left(\frac{\partial}{\partial \theta} L_\theta \right) \\
 &= \frac{\partial}{\partial \theta} \left(\frac{\partial}{\partial \theta} \log L_\theta \right) L_\theta \\
 &\quad - \left(\frac{\partial}{\partial \theta} \log L_\theta \right) \left(\frac{1}{L_\theta} \frac{\partial L_\theta}{\partial \theta} \right) \\
 &= \frac{\partial}{\partial \theta} \left(\frac{\partial}{\partial \theta} \log L_\theta \right) L_\theta \\
 &\quad - \left(\frac{\partial}{\partial \theta} \log L_\theta \right) \left(\frac{\partial}{\partial \theta} \log L_\theta \right) L_\theta
 \end{aligned}$$

Therefore, the squared derivative of the log-likelihood function with respect to θ is equal to the derivative of the derivative of the log-likelihood function with respect to θ multiplied by L_θ minus the derivative of the log-likelihood function with respect to θ multiplied by the derivative of L_θ with respect to θ . We started with this, and we have obtained this.

And therefore, what we are getting is the squared derivative of the log-likelihood function with respect to θ is equal to the derivative of the derivative of the log-likelihood function with respect to θ multiplied by L_θ minus the derivative of the log-likelihood function with respect to θ multiplied by the derivative of L_θ with respect to θ . This is equal to the derivative of the derivative of the log-likelihood function with respect to θ multiplied by L_θ minus the derivative of the log-likelihood function with respect to θ multiplied by the derivative of L_θ with respect to θ . And this, we can write as that we have already seen that it is the derivative of the derivative of the log-likelihood function with respect to θ multiplied by L_θ .

(Refer Slide Time: 49:40).

$$\begin{aligned} \text{Or } \left(\frac{\partial^2}{\partial \theta^2} \log L_\theta \right) L_\theta &= \frac{\partial}{\partial \theta} \left(\frac{\partial}{\partial \theta} \log L \right) L \\ &\quad - \left(\frac{\partial}{\partial \theta} \log L \right)^2 L_\theta \end{aligned}$$

\therefore On integrating both sides we have

$$\begin{aligned} E \left(\frac{\partial^2}{\partial \theta^2} \log L_\theta \right) &= \frac{\partial}{\partial \theta} E \left(\frac{\partial}{\partial \theta} \log L \right) \\ &\quad - E \left(\frac{\partial}{\partial \theta} \log L \right)^2 \end{aligned}$$

Or del square del theta square log of L theta into L theta, can be written as del del theta log L whole square into L theta. This is coming, because this is the same term, so it is square of del del theta log L theta square. Therefore, on integrating both sides, we have the expected value of del square del theta square log of L theta is equal to del del theta of expected value of del del theta of log L, I am integrating with respect to the pdf. Therefore, I get expected value of that one minus expected value of del del theta log L whole square.

(Refer Slide Time: 51:26)

Since we know

$$E \left(\frac{\partial}{\partial \theta} \log L \right) = 0$$

$$\therefore \boxed{E \left(\frac{\partial}{\partial \theta} \log L \right)^2}$$

\uparrow

$$I(\theta) = \boxed{- E \left(\frac{\partial^2}{\partial \theta^2} \log L_\theta \right)} - E \left(\frac{\partial^2}{\partial \theta^2} \log L_\theta \right)$$

Since, we know the expected value of $\frac{\partial}{\partial \theta} \log L$ is equal to 0, this we have found, before this part is going to be 0. Therefore, we can see that the expected value of $\left(\frac{\partial}{\partial \theta} \log L\right)^2$ is equal to minus of this thing. Expected value of $\frac{\partial^2}{\partial \theta^2} \log L$ is equal to minus of expected value of $\frac{\partial^2}{\partial \theta^2} \log L$. And we know that this is the $I(\theta)$.

Hence, we get another expression for $I(\theta)$, which is this minus of expected value of $\frac{\partial^2}{\partial \theta^2} \log L$. So, we have got three different forms. One from the actual proof, but from there we have derived two different forms, one is this one, and the other one is n into expected value of $\left(\frac{\partial}{\partial \theta} \log f\right)^2$.

So, in problem solving, we shall be using one of these forms. And we will be able to solve certain problems. So, in the next class, I will solve a few problems using Cramer-Rao inequality. And show that, how we obtain the lower bound in certain cases when we are dealing with the unbiased estimators for a function $g(\theta)$ of the parameter θ .

Ok students, thank you, seeing you in the next class.

Thanks.
