**Statistical Inference**

Welcome students to the MOOC's lecture on Statistical Inference. This is lecture number 16.

(Refer Slide Time: 00:26)

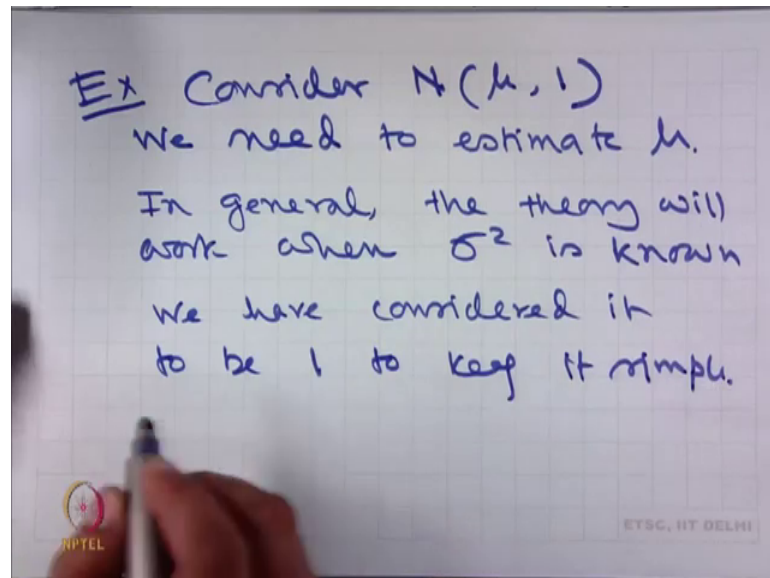

(Refer Slide Time: 00:35)

In the last lecture, we have discussed an important property namely sufficiency for estimating a parameter  $\theta$  and the condition was that a statistic  $T$  of  $x_1 \times 2 \times n$ , where  $x_1 \times 2 \times n$  is the sample values is said to be sufficient for estimating  $\theta$ . If the conditional distribution of  $X_1 \times 2 \times n$  given,  $T$  is equal to  $t$  is independent of  $\theta$ . So, let me first give you some more examples of sufficient statistic.

(Refer Slide Time: 02:09)

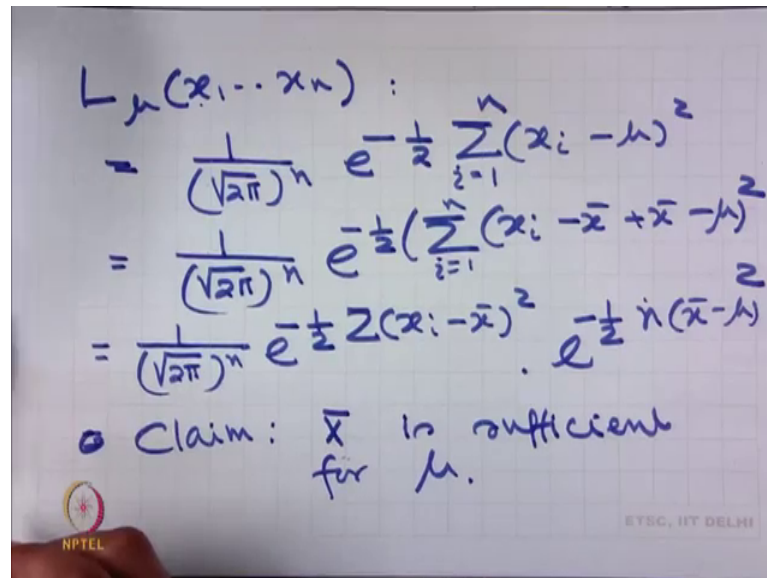

For example, consider normal  $\mu$  1. We need to estimate  $\mu$ . Note that the variance is already known in this case it is 1. In general the theory will work when sigma square is known. We have considered it 1 to keep it simple, ok.

(Refer Slide Time: 03:25)

$$\begin{aligned} L_{\mu}(x_1, \dots, x_n) &: \\ &= \frac{1}{(\sqrt{2\pi})^n} e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \mu)^2} \\ &= \frac{1}{(\sqrt{2\pi})^n} e^{-\frac{1}{2} \left( \sum_{i=1}^n (x_i - \bar{x} + \bar{x} - \mu) \right)^2} \\ &= \frac{1}{(\sqrt{2\pi})^n} e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \bar{x})^2} \cdot e^{-\frac{1}{2} n (\bar{x} - \mu)^2} \end{aligned}$$

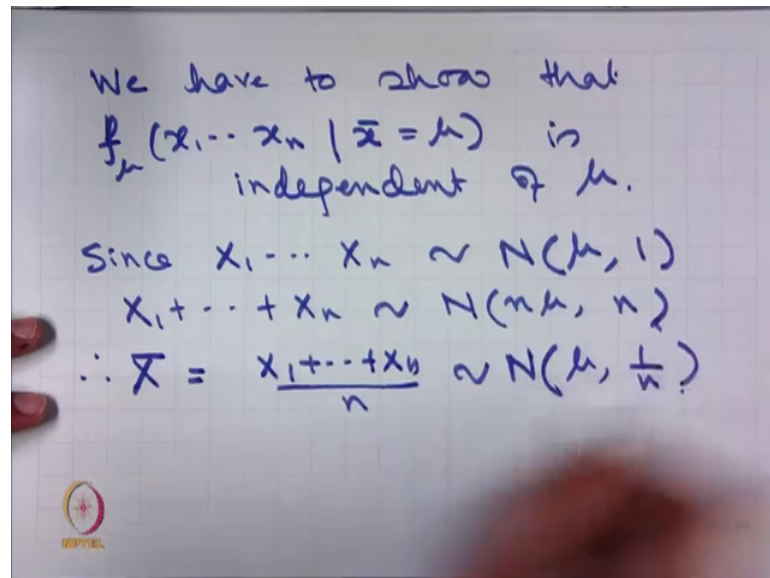

Claim:  $\bar{x}$  is sufficient for  $\mu$ .

So,  $L_{\mu}(x_1, \dots, x_n)$  that is joint density of  $x_1, \dots, x_n$  under the parameter  $\mu$  is equal to  $\frac{1}{(\sqrt{2\pi})^n} e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \mu)^2}$ . This is obvious because, the likelihood function here is the product of the individual density and we know that if  $x$  is normal  $\mu, 1$ , then the density of  $x$  is  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2} (x - \mu)^2}$ . Now, I am adding it because  $x_1, \dots, x_n$  there are  $n$  observations. So,  $L$  becomes the product of their individual densities. Therefore, in the exponent there being added is equal to  $\frac{1}{(\sqrt{2\pi})^n} e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \mu)^2}$ .

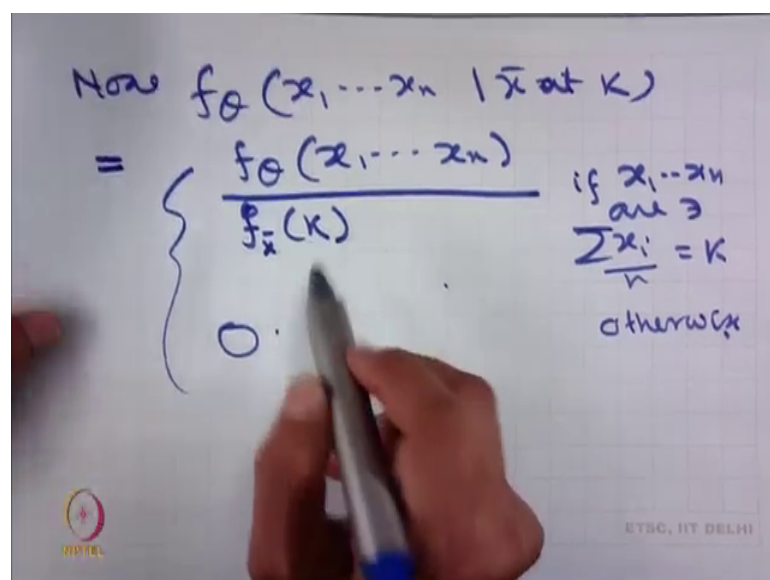

So, what we have done? I have subtracted and added  $\bar{x}$  so, this allows us to write it as  $e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \bar{x})^2} \cdot e^{-\frac{1}{2} n (\bar{x} - \mu)^2}$ . This is because this term is constant and it does not depend upon  $i$ . Therefore, as  $i$  is equal to 1 to  $n$ , the summation gives me  $n$  times  $(\bar{x} - \mu)^2$  and the product term will become 0 because  $\sum_{i=1}^n (x_i - \bar{x})$  will become 0. Claim  $\bar{x}$  is sufficient for  $\mu$ . So, what we are claiming that the sample mean is sufficient for  $\mu$ . So, what we have to show?

(Refer Slide Time: 06:26)

We have to show that joint density of  $x_1, x_2, \dots, x_n$  given  $\bar{x}$  is equal to  $\mu$  is independent of  $\mu$ . Since  $X_1, X_2, \dots, X_n$  are normal with mean  $\mu$  and variance 1,  $X_1 + X_2 + \dots + X_n$  is distributed as normal with  $n\mu$  and variance is equal to  $n$ . Therefore,  $\bar{X}$  is equal to  $(X_1 + X_2 + \dots + X_n) / n$  is distributed as normal with mean  $\mu$  and variance  $1/n$ .

(Refer Slide Time: 07:43)

Now,  $f_{\theta}(x_1, x_2, \dots, x_n, \text{ given } \bar{x} \text{ at } k)$  is equal to  $f_{\theta}(x_1, x_2, \dots, x_n)$  and divided by  $f_{\bar{x}}(k)$ . If  $x_1, x_2, \dots, x_n$  are such that  $\sum x_i / n = k$  or it

is 0, otherwise that is if  $x_1 \times x_2 \times \dots \times x_n$  are such that  $\bar{x}$  is not equal to  $k$ , then this becomes 0. Otherwise, it is the joint density of  $x_1 \times x_2 \times \dots \times x_n$  and of course, divided by the density of  $\bar{x}$  at  $k$  is equal to  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(k-\mu)^2}$  whole to the power  $n$  into  $e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \bar{x})^2}$  into  $e^{-\frac{n}{2}(\bar{x} - \mu)^2}$  whole square.

(Refer Slide Time: 08:55)

$$= \frac{\left(\frac{1}{\sqrt{2\pi}}\right)^n e^{-\frac{1}{2} \sum (x_i - \bar{x})^2} \cdot e^{-\frac{n}{2} (\bar{x} - \mu)^2}}{\left(\frac{1}{\sqrt{2\pi}}\right)^n e^{-\frac{1}{2} (k - \mu)^2}}$$

Independent of  $\mu$ .

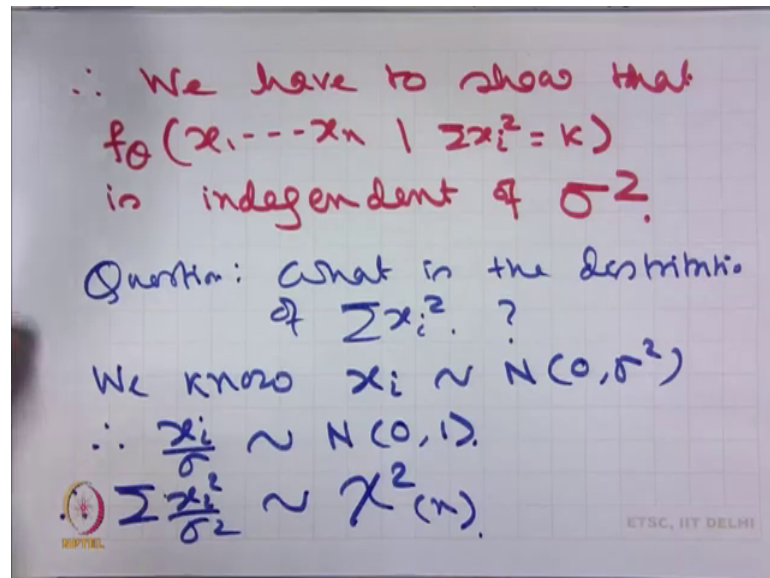

$$\therefore \bar{x} \sim N\left(\mu, \frac{1}{n}\right)$$

$$\frac{\left(\frac{1}{\sqrt{2\pi}}\right)^n e^{-\frac{1}{2} \sum (x_i - \bar{x})^2} \cdot e^{-\frac{n}{2} (k - \mu)^2}}{\left(\frac{1}{\sqrt{2\pi}}\right)^n e^{-\frac{1}{2} (k - \mu)^2}}$$

This we have already seen divided by since,  $\bar{x}$  is normal with mean  $\mu$  and variance is equal to  $1/n$ , this we can write it as  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(k-\mu)^2}$  whole to the power  $n$  and this is  $\bar{x}$  is equal to  $k$ . Therefore, this is nothing, but  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \bar{x})^2}$  into  $e^{-\frac{n}{2}(\bar{x} - \mu)^2}$  whole square divided by  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(k-\mu)^2}$  whole to the power  $n$  into  $e^{-\frac{1}{2} \sum_{i=1}^n (x_i - \bar{x})^2}$  into  $e^{-\frac{n}{2}(\bar{x} - \mu)^2}$  whole square. So, now you can see that this cancels with this and whatever remains, this is independent of  $\mu$  as the term  $\mu$  does not occur here.

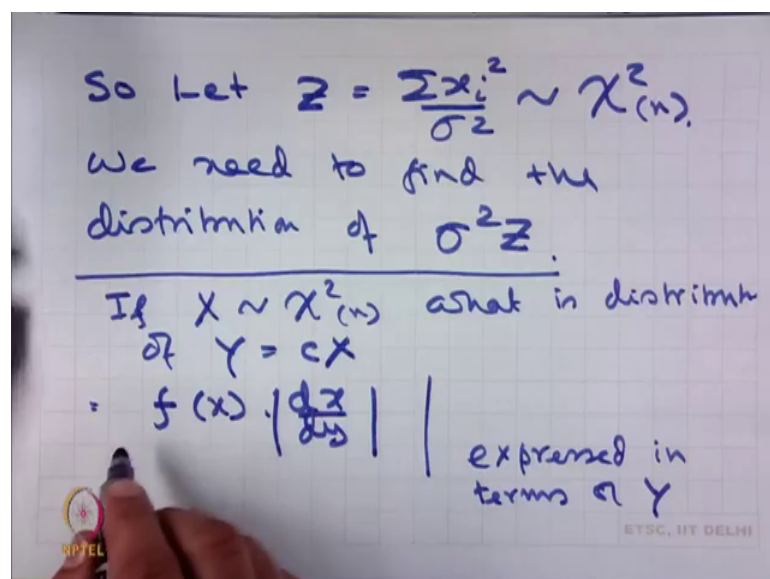

(Refer Slide Time: 13:37)

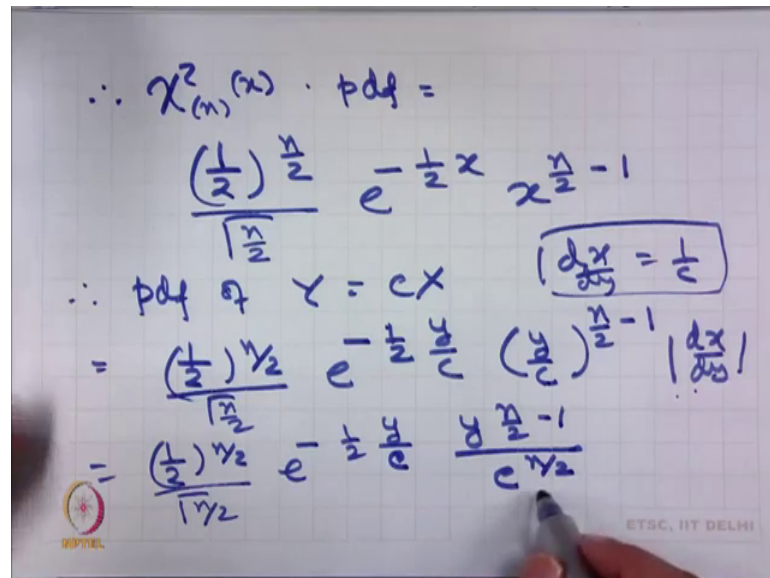

Therefore, we have to show that the joint density of  $x_1, x_2, \dots, x_n$  given  $\sum x_i^2$  is equal to  $k$  is independent of  $\sigma^2$ , then only we can show that  $\sum x_i^2$  is sufficient for  $\sigma^2$ . Question: What is the distribution of  $\sum x_i^2$ ? We know  $x_i$  is normal with  $0, \sigma^2$ . Therefore,  $x_i / \sigma$  is normal with  $0, 1$ . Therefore,  $\sum (x_i / \sigma)^2$  is distributed as chi square with  $n$  degrees of freedom.

(Refer Slide Time: 15:19)

So, let  $z$  is equal to  $\sum x_i^2$  upon  $\sum \sigma^2$  which is distributed as chi square with  $n$  degrees of freedom. We need to find the distribution of sigma square  $z$ . So, if  $x$  is chi square with  $n$ , what is the distribution of  $y$  is equal to  $c x$ . We know that this is equal to  $f$  at  $x$  multiplied by  $dx dy$  mod expressed in terms of  $y$ . So, this we have seen when we are working on functions of random variables.

(Refer Slide Time: 16:57)

$$\begin{aligned} \therefore \chi^2_{(n)}(x) \cdot \text{pdf} &= \\ &= \frac{\left(\frac{1}{2}\right)^{\frac{n}{2}}}{\Gamma\left(\frac{n}{2}\right)} e^{-\frac{1}{2}x} x^{\frac{n}{2}-1} \\ \therefore \text{pdf of } Y = cX & \quad \left(\frac{dx}{dy} = \frac{1}{c}\right) \\ &= \frac{\left(\frac{1}{2}\right)^{\frac{n}{2}}}{\Gamma\left(\frac{n}{2}\right)} e^{-\frac{1}{2} \frac{y}{c}} \frac{1}{c} \left(\frac{y}{c}\right)^{\frac{n}{2}-1} \left|\frac{dx}{dy}\right| \\ &= \frac{\left(\frac{1}{2}\right)^{\frac{n}{2}}}{\Gamma\left(\frac{n}{2}\right)} e^{-\frac{1}{2} \frac{y}{c}} \frac{1}{c} \frac{y^{\frac{n}{2}-1}}{c^{\frac{n}{2}-1}} \end{aligned}$$

So, this is equal to we know that chi square with  $n$  degrees of freedom at  $x$  has pdf is equal to half to the power  $n$  by 2 upon gamma  $n$  by 2  $e$  to the power minus half  $x$ ,  $x$  to the power  $n$  by 2 minus 1. Therefore, pdf of  $Y$  is equal to  $CX$  is half to the power  $n$  by 2 gamma  $n$  by 2  $e$  to the power minus half  $y$  by  $c$ ,  $y$  by  $c$  to the power  $n$  by 2 minus 1  $dx dy$  and since  $y$  is equal to  $cx$ ,  $dx dy$  is equal to  $1$  by  $c$ . Therefore, this is equal to half to the power  $n$  by 2 upon gamma  $n$  by 2  $e$  to the power minus half  $y$  by  $c$   $y$  to the power  $n$  by 2 minus 1 upon  $c$  to the power  $n$  by 2 because this is  $1$  by  $c$ . So, this  $c$  and this  $c$  and that it together we have  $c$  to the power  $n$  by 2.

(Refer Slide Time: 18:41)

$$\begin{aligned}
 \therefore \text{If } Z = \sum \frac{x_i^2}{\sigma^2} \sim \chi^2_{(n)} \\
 \text{then distribution of} \\
 \sum x_i^2 = \sigma^2 Z \\
 &= \frac{(\frac{1}{2})^{n/2}}{\Gamma(n/2)} e^{-\frac{y}{2\sigma^2}} \frac{y^{n/2-1}}{(\sigma^2)^{n/2}} \\
 &= \frac{(\frac{1}{2})^{n/2}}{\Gamma(n/2)} e^{-\frac{y}{2\sigma^2}} \frac{y^{n/2-1}}{\sigma^n} \quad \text{where } y = \sum x_i^2
 \end{aligned}$$

Therefore, if Z is equal to sigma x i square upon sigma square is distributed as chi square with n degrees of freedom, then distribution of sigma X i square is equal to sigma square z is equal to half to the power n by 2 gamma n by 2 e to the power minus half y upon sigma square y to the power n by 2 minus 1 upon sigma square to the power n by 2 is equal to half to the power n by 2 upon gamma n by 2 e to the power minus y 2 sigma square y to the power n by 2 minus 1 upon sigma square sigma to the power n, where y is equal to sigma xi square.

(Refer Slide Time: 20:15)

$$\begin{aligned}
 \therefore f(x_1, \dots, x_n | \sum x_i^2 = k) \\
 &= \frac{1}{(\sqrt{2\pi}\sigma)^n} e^{-\frac{1}{2\sigma^2} \sum x_i^2} \delta(\sum x_i^2 - k) \\
 &= \frac{(\frac{1}{2})^{n/2} e^{-\frac{\sum x_i^2}{2\sigma^2}} (\sum x_i^2)^{n/2-1}}{\Gamma(n/2) \sigma^n}
 \end{aligned}$$

After cancellation of  $x_1, \dots, x_n$  and  $\sum x_i^2 = k$  otherwise  $\sigma$ .

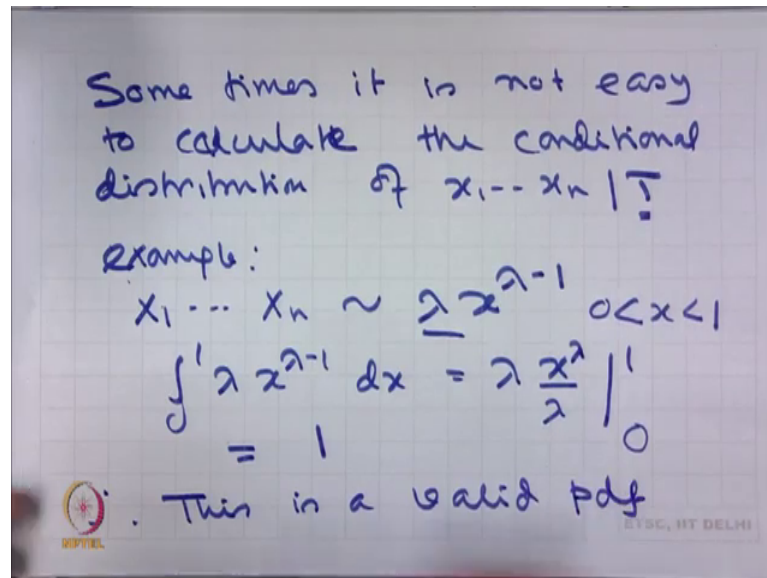

Therefore,  $f(x_1, x_2, \dots, x_n)$  given  $\sum x_i^2 = k$  is equal to  $\frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2} \sum x_i^2}$ .  $\sum x_i^2 = k$  is equal to  $k$  divided by  $\frac{1}{2}$  to the power  $n$  by  $2$  gamma  $n$  by  $2$   $e^{-\frac{1}{2\sigma^2} \sum x_i^2}$  upon  $2\sigma^2 \sum x_i^2$  to the power  $n$  by  $2$  minus  $1$  upon  $\sigma^2$  to the power  $n$  if  $x_1, x_2, \dots, x_n$  are such that  $\sum x_i^2 = k$  and  $0$  otherwise.

Now, let us look at this. This  $\sum x_i^2$  to the power  $n$  cancels this  $\sum x_i^2$  to the power  $n$  and  $e^{-\frac{1}{2\sigma^2} \sum x_i^2}$  upon  $2\sigma^2 \sum x_i^2$ . That also gets cancelled. So, we can see that after cancellation, there is any term involving  $\sigma^2$ . Therefore, what can we say? We can say that the distribution of  $x_1, x_2, \dots, x_n$  given  $\sum x_i^2 = k$  is independent of  $\sigma^2$  and therefore,  $\sum x_i^2$  is sufficient for estimating  $\sigma^2$ .

(Refer Slide Time: 22:40)

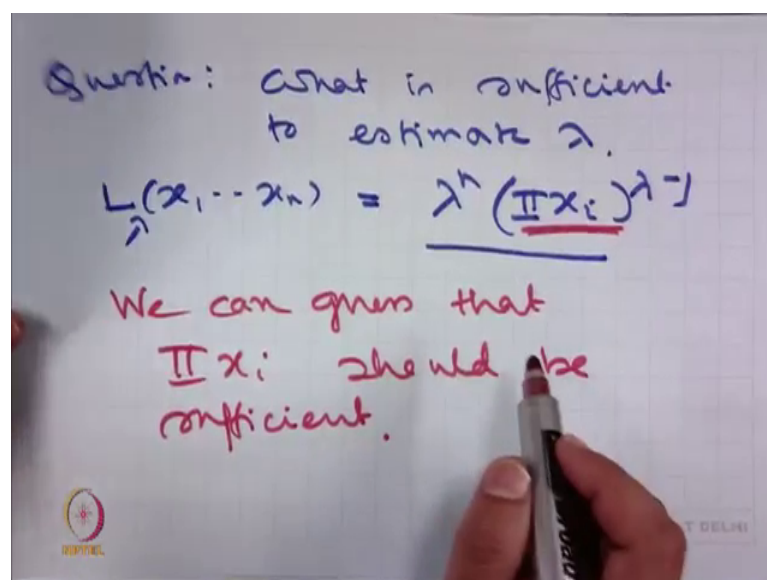

(Refer Slide Time: 22:58)

Sometimes, it is not easy to calculate the conditional distribution of  $x_1, x_2, \dots, x_n$  given  $T$  because we need to know the distribution of  $T$ . For example,  $X_1, X_2, \dots, X_n$  are from  $\lambda x^{\lambda-1}$   $0 < x < 1$  is a density integration  $\int_0^1 \lambda x^{\lambda-1} dx$  is equal to  $\lambda x^\lambda$  upon  $\lambda$   $0$  is equal to  $1$ . Therefore, this is a valid pdf.

(Refer Slide Time: 24:39)

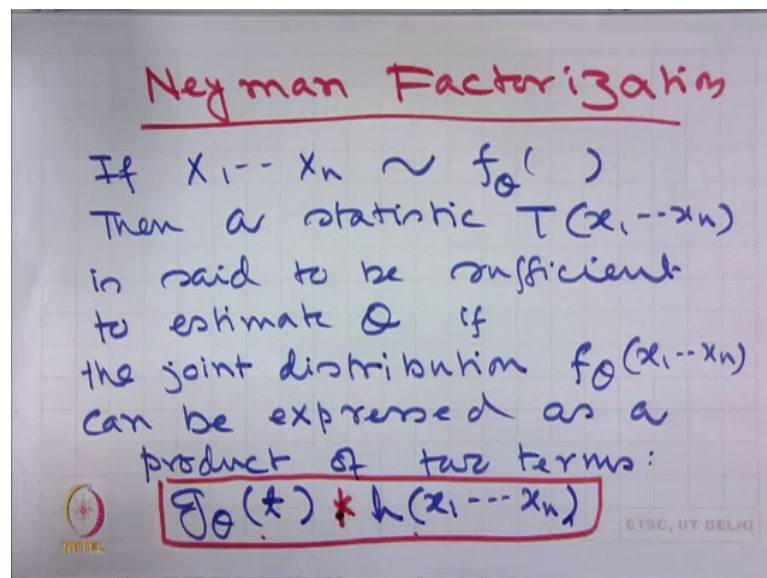

Question is what is sufficient to estimate  $\lambda$ ?  $L$  of  $x_1, x_2, \dots, x_n$   $\lambda$  is equal to  $\lambda^n$  into product of  $x_i$  to the power  $\lambda - 1$ . So, from here we can

see that the joint density of  $x_1, x_2, \dots, x_n$  depends upon only the product of  $x_i$ . So, it appears that to estimate  $\lambda$  only product of  $x_i$  is important. We do not need any other information just like that. In Bernoulli, we have observed that the joint density has been a function of  $\sum x_i$  and therefore, we could guess that  $\sum x_i$  could be sufficient for  $p$ .

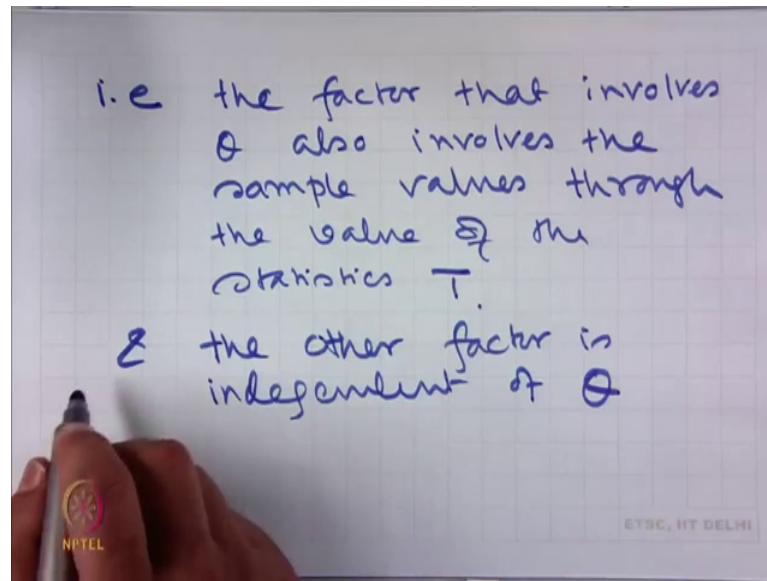

Similarly, in case of normal with  $\mu = 0$ ,  $\sigma^2$ , we could guess that  $\sum x_i^2$  will be sufficient to estimate  $\sigma^2$ . So, we can guess that product of  $x_i$  should be sufficient, but we cannot easily find that distribution of product of  $x_i$ . So, we need something else to establish sufficiency and that something else comes from Neyman Factorization.

(Refer Slide Time: 26:39)

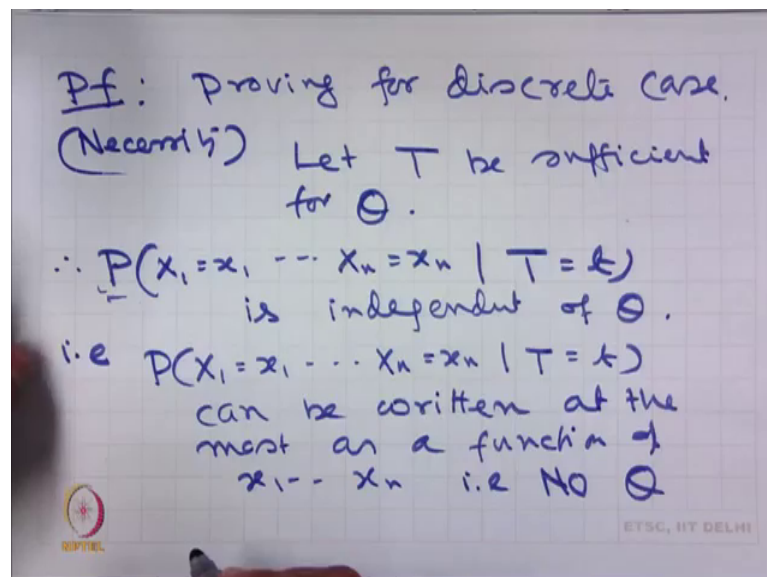

What he says that if  $X_1, X_2, \dots, X_n$  are coming from a distribution with parameter  $\theta$ , then a statistic  $T(x_1, x_2, \dots, x_n)$  is said to be sufficient to estimate  $\theta$  if the joint distribution  $f_\theta(x_1, x_2, \dots, x_n)$  can be expressed as a product of two terms  $g_\theta(t)$  multiplied by  $h(x_1, x_2, \dots, x_n)$  or in other words, let us look at these two terms; the joint distribution can be written as a product of two terms. The first term is involving the statistic  $t$  and also it is involving the parameter  $\theta$ . The product term  $h$  of  $x_1, x_2, \dots, x_n$  is a function of the sample values, but it does not involve  $\theta$ .

(Refer Slide Time: 28:57)

Therefore, what it is saying that is the factor that involves theta, also involves the sample values through the value of the statistics T and the other factor is independent of theta proof.

(Refer Slide Time: 29:57)

I am proving it for a discrete case for a continuous case. It can be proved analogously, but since it involves the function T. And therefore, it needs Jacobean that makes it little bit more complicated, but the conceptually it is the same.

So, the theorem is if and only if we will have to show both the parts, so necessity let  $T$  be sufficient for  $\theta$ . Therefore, probability  $X_1 = x_1$  up to  $X_n = x_n$  is equal to  $x_n$  given  $T$  is equal to  $t$  is independent of  $\theta$ . That is probability.  $X_1 = x_1$  up to  $X_n = x_n$  is equal to  $x_n$  given  $T$  is equal to  $t$  can be written at the most as a function of  $x_1 \times 2 \times n$ . That is NO  $\theta$ .

(Refer Slide Time: 32:15)

$\therefore$  Let  
 $P(X_1 = x_1, \dots, X_n = x_n | T = t)$   
 $= h(x_1, \dots, x_n)$   
 $P(X_1 = x_1, \dots, X_n = x_n | T = t)$   
 $= \begin{cases} \frac{P(X_1 = x_1, \dots, X_n = x_n)}{P(T = t)} & \rightarrow \text{as when } x_1, \dots, x_n \text{ are } \exists T(x_1, \dots, x_n) = t \\ 0 & \text{otherwise} \end{cases}$

RPAPL ETSC, IIT DELHI

Therefore, let probability  $X_1 = x_1$  up to  $X_n = x_n$  given  $T$  is equal to  $t$  is equal to say  $h$  of  $x_1 \times 2 \times n$ . Now, the left hand side upon probability  $T$  is equal to  $t$  whereas, before  $x_1 \times 2 \times n$  are such that  $x_1 \times 2 \times n$  is equal to  $t$  and it is equal to 0 otherwise. So, we can ignore this part.

(Refer Slide Time: 33:41)

$$\begin{aligned} \therefore P(X_1=x_1, \dots, X_n=x_n) &= P_0(T=t) h(x_1, \dots, x_n) \\ &\quad \uparrow \\ &\quad g_\theta(t) \end{aligned}$$

$\therefore$  We can write the joint distribution as a product of two terms

- $g_\theta(t)$  involving  $t$  &  $\theta$
- $h(x_1, \dots, x_n)$  that does not involve  $\theta$

Therefore, probability  $X_1$  is equal to  $x_1$ ,  $X_2$  is equal to  $x_2$ , ...,  $X_n$  is equal to  $x_n$  is equal to probability  $T$  is equal to  $t$  into  $h$  of  $x_1, x_2, \dots, x_n$ . Let us call it  $g_\theta(t)$  because this probability will automatically involve the parameter  $\theta$ . Therefore, we can write the joint distribution as product of two terms  $g_\theta(t)$  involving  $t$  and  $\theta$  and  $h$  of  $x_1, x_2, \dots, x_n$  that does not involve  $\theta$  conversely.

(Refer Slide Time: 35:07)

Conversely Suppose the above condition holds, i.e.  $P_\theta(x_1, \dots, x_n) = g_\theta(t) h(x_1, \dots, x_n)$

$$\begin{aligned} \therefore P_0[T=t] &= \sum_{\substack{x_1, \dots, x_n \\ T(x_1, \dots, x_n)=t}} P_\theta(x_1, \dots, x_n) \\ &= \sum_{\substack{x_1, \dots, x_n \\ T=t}} g_\theta(t) h(x_1, \dots, x_n) \end{aligned}$$

Suppose the above condition holds that is  $P_\theta$  of  $x_1, x_2, \dots, x_n$  is equal to  $g_\theta(t)$  into  $h$  of  $x_1, x_2, \dots, x_n$ . Therefore, probability  $P_0$  of  $T$  is equal to say  $t$  is equal to summation

over all those  $x_1 \times 2 \times n$ , such that  $T \times 1 \times 2 \times n$  is equal to  $t$  of  $P_\theta$  of  $x_1 \times 2 \times n$ . That is all those values of  $x_1 \times 2 \times n$  that generates the value of the statistics  $T \times 1 \times 2 \times n$  to be  $t$ . I have to sum them up to find the probability that the statistic  $T$  is equal to small  $t$  is equal to  $\sum_{x_1 \times 2 \times n, \text{ such that } T \text{ is equal to } t} g_\theta(t) \int h(x_1 \times 2 \times n) dx_1 \times 2 \times n$  is equal to  $g_\theta(t) \int h(x_1 \times 2 \times n) dx_1 \times 2 \times n$ .

(Refer Slide Time: 36:59)

$$= g_\theta(t) \sum_{x_1, \dots, x_n} h(x_1, \dots, x_n) \quad \text{where } T(x_1, \dots, x_n) = t$$

$$\therefore P_\theta(x_1, \dots, x_n | T=t) = \begin{cases} \frac{g_\theta(t) / h(x_1, \dots, x_n)}{g_\theta(t) \sum_{x_1, \dots, x_n} h(x_1, \dots, x_n)} & \text{where } T(x_1, \dots, x_n) = t \\ 0 & \text{otherwise.} \end{cases}$$

proved.

Therefore, the conditional density  $P_\theta$  of  $x_1 \times 2 \times n$  given  $T$  is equal to  $t$  is equal to  $g_\theta(t) \int h(x_1 \times 2 \times n) dx_1 \times 2 \times n$  divided by  $g_\theta(t) \int h(x_1 \times 2 \times n) dx_1 \times 2 \times n$ , such that  $x_1 \times 2 \times n$  are such that  $T \times 1 \times 2 \times n$  is equal to  $t$  from here, otherwise it is 0. That is when  $T$  of  $x_1 \times 2 \times n$  is equal to  $t$ . Now, if I look at this, this is surely independent of  $\theta$  and if I look at this, this cancels out. Therefore, the term remains is completely independent of  $\theta$ .

Therefore, it satisfies that the conditional density of  $x_1 \times 2 \times n$  given  $T$  is equal to small  $t$  is independent of  $\theta$ . Therefore, that is a necessary and sufficient condition to check if the given  $t$  is a sufficient statistic to estimate  $\theta$ .

(Refer Slide Time: 39:14)

Some Sufficient Statistics

Bin( $m, p$ )  $x_1, \dots, x_n$   $n$  samples  
we want to estimate  $p$

$$L(x_1, \dots, x_n) = \binom{m}{x_1} p^{x_1} (1-p)^{m-x_1} \dots \binom{m}{x_n} p^{x_n} (1-p)^{m-x_n}$$
$$= \prod_{i=1}^n \binom{m}{x_i} p^{\sum x_i} (1-p)^{mn - \sum x_i}$$

$\therefore \sum x_i$  is sufficient for  $p$ .

When you look at the joint density, if we look at the term involving  $x_1 \times 2 \times n$  in which form it is associated with the joint density that gives us a clue of how to obtain a sufficient statistic. For example, binomial with  $m, p$  and suppose  $X_1, X_2, \dots, X_n$  are  $n$  samples we want to estimate  $p$ , then the joint density of  $L(x_1, x_2, \dots, x_n)$  is equal to  $m \times x_1 p$  to the power  $x_1$   $(1-p)$  to the power  $m - x_1$  into up to  $m \times x_n p$  to the power  $x_n$   $(1-p)$  to the power  $m - x_n$  is equal to product of  $m \times x_i$ ,  $i$  is equal to 1 to  $n$   $p$  to the power  $\sum x_i$   $(1-p)$  to the power  $mn - \sum x_i$ .

Therefore, if you look at the joint density of  $x_1, x_2, \dots, x_n$ , we find that the sample values are involved here in the form of  $\sum x_i$ . What does it say? It says that  $\sum x_i$  is good enough for us to estimate  $p$ . Therefore,  $\sum x_i$  is sufficient for  $p$ .

(Refer Slide Time: 41:37)

Similarly Let us consider  
 Beta,  $(\alpha, \beta)$   $\alpha$  is known.  
 $\therefore f(x_1, \dots, x_n) = \prod_{i=1}^n \frac{\alpha + \beta}{\alpha \beta} x_i^{\alpha-1} (1-x_i)^{\beta-1}$   
 $0 < x_i < 1$   
 $\therefore$  We can see that  
 the term that involves  
 $\beta = \prod_{i=1}^n (1-x_i)$

Similarly, let us consider beta 1 alpha beta where alpha is known. Therefore, f of x 1 x 2 x n 0 less than x i less than 1 is equal to product of gamma alpha plus beta upon gamma alpha gamma beta x i to the power alpha minus 1 1 minus x i to the power beta minus 1. Therefore, we can see that the only term that involves beta is equal to product of 1 minus x i. Therefore, we can say that this is sufficient to estimate beta.

(Refer Slide Time: 43:19)

Sometimes it is not easy  
 to visualize the sufficient  
 statistic.  
 $X_1, \dots, X_n \sim U(0, \theta)$   
 i.e.  $f_{\theta}(x_i) = \begin{cases} \frac{1}{\theta} & 0 \leq x_i \leq \theta \\ 0 & \text{otherwise} \end{cases}$   
 What is sufficient for  $\theta$ ?  
 Diagram: A horizontal line segment from 0 to  $\theta$ . The interval is marked with a red line and contains several black dots representing data points. The value  $\theta$  is labeled as 'unknown'.

Still sometimes it is not easy to visualize the sufficient statistic. For example,  $X_1, X_2, \dots, X_n$  are from uniform  $0, \theta$  that is  $f_{\theta}(x_i)$  is equal to  $1/\theta$  for  $0 \leq x_i \leq \theta$  and 0 otherwise.

$x_i$  less than equal to  $\theta$ , otherwise what is sufficient for  $\theta$  suppose I ask you the question. Now,  $0 < \theta$  this  $\theta$  is unknown to us.

Now, I have taken  $n$  samples from here, what we can say that this is the highest order statistic. Only thing that we can say is  $\theta$  is greater than equal to this value and since  $\theta$  is greater than equal to this value, we know none of these observations have any influence on that decision making or in other words, the best estimate that we can do for  $\theta$  is true the  $n$ th order statistic or  $x_n$ . Therefore, we can say that  $x_n$  is the sufficient statistic to estimate  $\theta$  how to do it mathematically.

(Refer Slide Time: 45:45)

To do it mathematically  
 Let us define a function  

$$k(a, b) = \begin{cases} 1 & \text{if } a < b \\ 0 & \text{if } a \geq b \end{cases}$$

$$\therefore f_{\theta}(x_i) = \frac{k(0, x_i) \cdot k(x_i, \theta)}{\theta}$$

$$\therefore L_{\theta}(x_1, \dots, x_n) = \prod_{i=1}^n \frac{k(0, x_i) \cdot k(x_i, \theta)}{\theta} = \frac{\prod_{i=1}^n k(0, x_i) \cdot k(x_i, \theta)}{\theta^n}$$

Let us define a function  $k$  of  $a, b$  which is 1 if  $a < b$  and 0 if  $a$  is greater than equal to  $b$ . Therefore,  $f_{\theta}$  of  $x_i$  is equal to  $k$  of  $0, x_i$  times  $k$  of  $x_i, \theta$  divided by  $\theta$  and it will be 1 only if  $x_i$  is greater than 0 or greater than equal to 0 and less than  $\theta$ . So, only in these cases when  $a < b$   $k$  is 1, so when 0 is less than  $x_i$  and  $x_i$  is less than  $\theta$ , then this will be 1 and therefore, this is going to be  $f_{\theta}$  of  $x_i$  for each  $x_i$ . Therefore,  $L_{\theta}$  of  $x_1, x_2, \dots, x_n$  is equal to product of  $i$  is equal to 1 to  $n$   $k$  of  $0, x_i$   $k$  of  $x_i, \theta$  upon  $\theta$  to the power  $n$  or in other words, this is saying that the joint density function is a product of these terms.

(Refer Slide Time: 48:17)

$$\begin{aligned}K(0, x_i) &= 1 \quad \forall x_i \\ \Rightarrow 0 &< \min \theta \quad \forall x_i \\ \&K(x_i, \theta) &= 1 \Rightarrow \forall x_i \\ \Rightarrow x_i &< \theta \quad \forall x_i \\ \therefore L_{\theta}(x_1, \dots, x_n) &= \\ &\frac{K(\max x_i, \theta)}{\theta^n} \times K\left(\min x_i, 0\right) \\ \text{This suggests that } X_{(n)} &\text{ is sufficient for } \theta.\end{aligned}$$

Now,  $K(0, x_i)$  is equal to 1. For all  $x_i$  implies 0 is less than minimum of all  $x_i$  and  $K(x_i, \theta)$  is equal to 1 implies for all  $x_i$  implies  $x_i$  is less than  $\theta$  for all  $x_i$ . Therefore,  $L_{\theta}(x_1, x_2, \dots, x_n)$  can be written as  $K(\max x_i, \theta)$  upon  $\theta^n$  multiplied by  $K(\min x_i, 0)$ . Therefore, the term that involves  $\theta$  is maximum over  $x_i$  say for these suggest that  $X_{(n)}$  is sufficient for  $\theta$ , ok.

Students with that I stop here today. So, over the last 3 lectures, we have studied different properties of the estimators namely unbiasedness, consistency, efficiency and today we have seen examples of sufficient statistic. In the next class, I shall be dealing with how do we actually estimate a parameter from the observations  $x_1, x_2, \dots, x_n$  or in other words, methods of estimation.

Thank you so much.
