

Ordinary Differential Equations (noc 24 ma 78)

Dr Kaushik Bal

Department of Mathematics and Statistics

Indian Institute of Technology, Kanpur

Week-05

Lecture 32

Welcome students to this video on Stumbleable Problems. This is one of the most important aspects of the study of ODEs. So, what is this topic about? We are essentially interested in the equation like this, a second order equation given by $P''(x) + P_1(x)y' + P_2(x)y = r(x)$. Let us say, let us call that 1. So this is your second order equation.

Is it okay? Now this is defined on some α β . Defined let us say in α β . α , β . And here we are assuming P_0 , P_1 , P_2 and R are to be smooth.

So, you know, maybe sufficiently, you know, C_1 , C_2 , whatever is that you can choose is not a big problem. And we also have the boundary data right what is the boundary data so first of all we'll call it L_1 of y let's just call it like this which is given by $a y' + b y$ at the point α plus $a_1 y'$ at the point α plus $b_1 y$ at the point β plus $b_1 y'$ at the point β let's just call that to be L_2 . And there is another condition L_2 of y which is again the similar sort of condition but with C_0 and D_0 . $C_0 y$ at the point α plus $C_1 y'$ at the point α plus $D_0 y$ at the point β plus $D_1 y'$ at the point β .

This is B. this is okay so L_1 and L_2 if those two are uh these two sort of conditions are there so basically one along with these two conditions here a b c d a and b are constants okay are constants now we want to study this problem now you see this problem if you remember we have seen that for Some values, it will depend on the value of the initial data, depend on L_1 and L_2 . But the thing is, this problem may have solution, may have unique solution, may have no solution or may have infinitely many solutions, right? We have already seen that part.

Now, the thing is this, you see, a very important aspect in mathematical physics, okay, is to determine, see, if let us say, if we put λ over here, let us say, λ over here.

Okay, let us, so essentially, let me write it this way. Let us say, now, if we have a boundary value problem, which will look like this, $py' + qy + \lambda r y = 0$. Let us just say if we have a problem like this.

Is it okay? Right. So see R is here I wrote R like this. So basically think of it as R to be 0 and the thing is $P2$ looks like this. Okay.

$Q + R Y R \lambda R$. Sorry. Yes. And this sort of equation, basically in mathematical physics, what happens is there are many different situations where you have to determine the value of this parameter λ . Okay. So the question generally arises as determine λ .

Determine λ . Okay. So the value of λ theta. Here you see a λ is in a complex number C . That's what we generally assume. Okay.

For which non-trivial solutions exist. Non-trivial solutions exist. Exist. Okay. See it is not that this is only from mathematical physics.

Even we doing you know solving some pd 's and all. We actually are going to need this sort of problem. So this is a very very important class of problems. These are called Sturm-Liouville boundary value problems. Okay.

So we are going to study this problem. So basically what is the equation? The equation is given by this. Let's just call this 2. Yes.

And so 2 along with uh maybe i can write it like this right maybe i can write this as okay let me I should introduce the problem properly. So essentially, okay. So let me do it properly, okay?

So you got the idea. Essentially, this is the equation. And for this equation, you have to find, so you have to find λ 's for which, you know, non-trivial solutions exist. You do realize that for all λ , it may happen that for some λ , there are one solution, unique solution, right? For some λ , there is no solution.

For some λ , there may be many solutions, okay? So we have to keep track of such λ 's for which there are non-trivial solutions. And what is the boundary data? That we have to determine. So what I am going to do is maybe introduce the problem in the next page properly.

Let me do it this way. See, the thing is, first of all, in 1, let me introduce it in this way. See, consider 1 with rx equals to 0. So basically it is a homogenous problem. rx equals to 0 yeah now you see for the homogeneous problem what happens is this if you are i mean this problem is in the general form right now if you multiply it properly with the integrating factor and all we know we can actually uh write it in terms of a self-adjoint operator okay so write one write one in terms of self-adjoint operator terms of self-adjoint operator

adjoint operator operator okay and then what happens is if we can write it in terms of self adjoint operator then it will look like this $py' + qy$ right this whole form see then this $p' y'' + p_1 y' + p_2 y$ may be written as okay can you we have seen right we can write it as $p y' + qy$ Now the question is this that let us say that if this is equal to let us say λ times some $r y$. Okay. λ can be positive, negative, doesn't matter, but λ , it can be compressed also. So let's say we want to find out for which values of this, this is equals to λ times ry .

Okay. Then these sort of problems are called Sturm-Liouville boundary value problems. If you write it properly, you see what is happening is, let's say this is the operator L of y . and let us say r is 1 for now, then it will look like λ times y . You see, these sort of equations are the eigenvalue problems, right? So, basically, we are trying to find out the eigenvalues of L and the eigenfunctions, of course, okay?

So, these sort of equations are called eigenvalue problems. So, basically, some of the problems are called eigenvalue problems because of this reason, okay? Now, so let me now formally introduce the problem, and then we are going to look at some properties of this, okay? So, consider the Consider the differential equation.

Sturm-Liouville Problem :-

$$p_0(x)y'' + p_1(x)y' + p_2(x)y = r(x) \text{ --- (I) defined in } [a, b]$$

here p_0, p_1, p_2 and r to be smooth

and $l_1(y) = a_0 y(a) + a_1 y'(a) + b_0 y(b) + b_1 y'(b) = A$
 $l_2(y) = c_0 y(a) + c_1 y'(a) + d_0 y(b) + d_1 y'(b) = B.$

a_i, b_i, c_i, d_i, A and B are constant.

Now, $(py')' + qy + \lambda ry = 0 \text{ ; } \lambda \in \mathbb{C} \text{ --- (II)}$

Q:- Determine λ for which non-trivial solutions exist.

Consider (I) with $r(x) = 0$, write (I) in terms of self-adjoint operator:

$$p_0 y'' + p_1 y' + p_2 y \simeq (py')' + qy = \lambda ry.$$

$(Ly = \lambda y) \leftarrow \text{Eigenvalue}$

What is the differential equation? It is given by $p y$ prime whole prime, okay? See, first of all, again, anyways, this term-level boundary-value problem, we are always considering, going to consider a self-actual differential equation, okay? So, plus $q y$ plus $\lambda r y$, okay, equals to 0. That is the equation given to us.

Yes. And of course, P and Q . Let me write it down. So P and Q are continuously differentiable. Continuously differentiable. P and Q are continuously differentiable.

This is given to us. What is λ ? λ is a parameter. For the starters, what we are going to do is we are going to assume λ is some number is a parameter which is varying at, you know, in \mathbb{C} . So basically λ will be from \mathbb{C} . That's what we are going to assume. OK.

OK. So this is there. And very important property. So these properties are very, very important in order for this problem to work. OK.

p and r are positive. Please remember this thing. Very, very important, okay? Without these properties, none of the things which I am going to do is going to work, okay? So, first of all, p is this, yeah?

The first coefficient. r is this, the coefficient corresponding to λ . Those two problems. So, okay? We are going to assume the problem, you see.

First of all, we are going to write it like this. $ly + \lambda ry$ equals to 0. Here, this λ corresponding to, this r corresponding to λ will be called a weight function. This is called a weight function. Is this okay?

We will call it like this. And we will write this operator like this, $ly + \lambda ry$ equals to 0. Is it okay? Yeah, this is the form which we are going to write it. Again, if we are writing like this, please, please remember p has to be positive.

The first coefficient p corresponding to py' whole prime. Okay. This p has to be positive and along with that λ , the r which is along with λ , the weight function r , that has to be positive. These two conditions is vital for this sort of thing to work. Is it okay?

Otherwise, you know, the problem is this. Without this, if you want to do this problem, so what happens is, first of all, you know that if p is 0 or something like that, then, I mean, we can have that this is Lothar regular problem, boundary value problem, okay? So, this will be, in this case, a singular boundary value problem. And, of course, we are also assuming all of these in a closed interval α β . That is also there.

Closed interval α β . Why? Because again, we are basically looking at regular boundary value problem. You see, of course, what are the boundary data along with the boundary data? Along with the boundary data, what is the boundary data?

We are going to assume this boundary data. $a_0 y$ at the point α , plus $a_1 y'$ at the point α is 0, okay? And $d_0 y$ at the point β plus $d_1 y'$ at the point β is 0. This is okay.

These are the two boundary conditions which you are going to assume along with this equation. So, let us for now, let us call this equation as star, okay? The whole thing, yes,

the equation along with the boundary. So, maybe I can write it here, star. This is the star problem.

This is the problem which we want to study for next few one or two, I mean, you know, videos. Whenever we are talking about Sturm-Liouville boundary value problem, we are going to look at this particular problem. We will call it a Sturm-Liouville boundary value problem. boundary value problem. Is it OK?

Sturm level boundary value problem, OK? And generally speaking, we also go, I mean, like to call it as an eigenvalue problem. So that also is generally done, OK? And please remember, this is the data which we have considered, p , q , the interval i , the α , β . So this is, of course, a regular boundary value problem.

So it is generally there. It is also called a regular Sturm level boundary value problem. Is it OK? Because this is a regular data, right? Regular boundary data.

This we already know. So, it looks like this, okay? See, the thing is the λ s which we are going to find. So, basically a small note here. Now, what is the problem?

The problem is to find λ , right? Those will be called as eigenvalues, right? eigenvalues. Clear? And the corresponding non-trivial solutions.

Is it okay? This is the problem. Corresponding non-trivial solutions you have to find. And we will call it a ϕ_λ of x , right.

So, any solutions of this for a given λ , any solution will look like ϕ_λ , right, which is again a function. So, it is sufficient regularity, yes. So, in C^2 of i , i is i . So, this is defined in i , right. All of this is in i , which is α β , let us say. If you remember, and this is finite, those boundaries are I to R , that sort of function, okay?

Non-trivial function. This will be called eigenvectors. If you remember, this is called eigenvectors, right? Or eigenfunctions also we will call it. It is not a problem.

Synonymously, it is also called eigenfunctions. So, I am going to call it eigenvectors or eigenfunctions, whatever, I mean, everything is fine. It is not a problem, okay? Now, if you put all the set of all eigenvalues, okay?

Now, again, also, the set of all eigenvalues, all eigenvalues. So, if you take the set of all eigenvalues together, right, of a regular problem of star, okay? That set is called the spectrum. okay what is spectrum of what spectrum of some operator right so the operator

is given by $(py')' + qy + \lambda ry = 0$ where p, q, r are continuous functions on $J = [a, b]$. This is the operator. So that is as you understood is it okay right so that is the whole problem that's the introduction of the problem okay so now let's work out one you know example and then we go to the theory part so first of all how do we compute such eigen value and eigen function let's just look at that So you see, first of all, consider this problem.

Consider the DE

$$(py')' + qy + \lambda ry = 0 \quad p \text{ and } q \text{ are continuously differentiable} \quad J = [a, b]$$

λ is a parameter and $p, r > 0$.

along with the boundary data.

$$a_0 y(a) + a_1 y'(a) = 0$$

$$b_0 y(b) + b_1 y'(b) = 0$$

Sturm-Liouville Boundary Value Problem (Regular).

Note: Problem is to find λ (eigenvalues) and the corresponding ^{non}trivial solutions $\phi_\lambda(x) \in C^2(J; \mathbb{R})$
 = (eigenvalues) (eigenfunctions)
 also, the set of all eigenvalues of \mathcal{L} is called the spectrum

Consider $(py')' + qy + \lambda ry = 0$. Is it okay? And then $y(0) = y(a)$ at the point a equals to 0. Yes? If you remember, see here, if you assume p is, of course, 1.

Here, here, P of x is identically equals to 1. Okay. What is Q of x ? Q of x is essentially 0.

And what is R of x ? R of x is essentially 1. Okay. So, you see here for the problem P and R has to be positive. Q can be anything.

I do not care. You can be negative, positive, whatever. As long as Q is continuous, it is fine. Okay. And the data is given on 0 and a .

0 and a , what sort of, I mean... do I put it what sort of interval it is it is a closed and bounded interval right so what sort of problem is it can you think of it what is it called this sort of problem so this sort of problem is called regular Sturm-Liouville boundary value problem okay so we call this sort of problem is what is it regular so we'll I will write it like this huh regular term Sturm-Liouville boundary value problem is this okay we'll call it this right okay now how do you solve this thing so first of all see what we are going to do is I'm just going to concentrate on λ in \mathbb{R} okay so we are going to we are going to concentrate concentrate on λ in \mathbb{R} . So what I mean by this C . Generally speaking λ can be in C right. But the thing is we are not really interested in C right now.

Why not? That will be covered in the theory part okay. So you do not have to look for λ in \mathbb{C} . So essentially if there are λ s. okay for which non-trivial solutions exist those λ s has to be real for this sort of problem okay that's come that comes from theory so you don't have to worry about it all you have to worry about it is the real λ s okay so first of all so what can be the cases first of first case is either λ is zero or λ can be non-zero or a positive or negative right okay so first of all if λ is zero if λ is zero Okay, then what happens to this equation $y'' = 0$ and the general solution y of x will look like $c_1 + c_2 x$. Is it okay?

And c_1, c_2 is in \mathbb{R} . c_1, c_2 is in \mathbb{R} . Okay, and you see it satisfies these two equation and you see $0 = y$ at the point 0 . That is nothing but $c_1 + c_2 \cdot 0$. Okay, that will give you $c_1 = 0$. Now if $c_1 = 0$, if you are putting it like this, then $y = c_2 x$, right? Now, therefore, what we have is y of x is nothing but $c_2 x$. Now it also has to satisfy the other condition.

So what is the other condition? $0 = y$ at the point π , right? So which is nothing but $c_2 \pi = 0$. That will imply c_2 has to be 0 , right?

Hence, c_1 and c_2 is 0 . So, y identically equals to 0 . Is it okay? That is the only solution available. Now, you see what is the question?

The question is this. You have to find, please remember, you have to find λ s for which non-trivial solution exists. See, this is the homogeneous problem, right? So, for any λ , trivial solution exists, right? See, let me put it as a small remark.

See, these regular sum-level boundary value problems, they are homogeneous problems. So for any λ , for any λ , trivial solution is always a solution, right? For any λ , trivial solution exists. Solution exists. exists.

Is it okay? Now, the thing is, this trivial solution is fine, but what about the other non-trivial solutions? Okay. Now, you have to find, if you have to find something like that, then you have to work out. So, basically, you have to find out λ s for which non-trivial solution exists.

So, here you see, if $\lambda = 0$, you will see that $\lambda = 0$ is the only solution. Is it okay? So, the thing is, since this is the case, therefore, $\lambda = 0$ is not an eigenvalue. It is not an eigenvalue.

Is it okay? It is not an eigenvalue. Okay. Right. So, this is case 1, let us say.

Case 2. Let us say lambda is not 0. So, if lambda is non-zero and lambda can be positive negative. So, lambda is let us say mu square. Okay.

Mu not 0. Clear? So, it is non-zero basically. So, in that case, then the equation which you have is y double prime plus mu square y equals to 0. Is it okay?

And that will imply yx equals to c1 times cosine mu x plus, one second, this is plus minus m square, what is the solution? m square plus mu square. So, c1 plus c2 times sine mu x. Sine mu x, yes, right? That is what the solution is.

Yes, I hope this is, I am correct. Yes, fine. Now, c1 and c2 is of course in R. c1 and c2 is in R. Just give it. Now, see, if this is the case, if this is the case, now you have to satisfy that equation. So, what is it?

Ex: Consider $y'' + \lambda y = 0$ ✓
 $y(0) = y(\pi) = 0$. } - (B.V.P)

Here, $p(x) \equiv 1, q(x) \equiv 0, r(x) \equiv 1$.
 We are to concentrate on $\lambda \in \mathbb{R}$,

1. If $\lambda = 0$, $y(x) = c_1 + c_2 x$; $c_1, c_2 \in \mathbb{R}$
 $0 = y(0) = c_1 + c_2 \cdot 0 \Rightarrow c_1 = 0 \Rightarrow y(x) = c_2 x$.
 $0 = y(\pi) = c_2 \cdot \pi \Rightarrow c_2 = 0$.
 Hence, $y(x) \equiv 0$
 $\therefore \lambda = 0$ is not an eigenvalue.

2. If $\lambda \neq 0$ and $\lambda = \mu^2$ ($\mu \neq 0$) then $y'' + \mu^2 y = 0 \Rightarrow y(x) = c_1 \cos \mu x + c_2 \sin \mu x$; $c_1, c_2 \in \mathbb{R}$.

Remark: - For any λ , trivial solution exists.

First of all, the first equation is this, 0 equals to y at the point 0. And what is this y at the point 0? c1 times sine mu 0 plus c2 times, I have wrote it as sine cosine, right, or cosine sine. So, I should write it properly. So, cosine mu x plus sine mu x. So, I should write it like cosine mu 0 plus c2 times sine mu 0.

Is it okay? Yes, now you see sin 0 is 0 essentially. So, c1 times cosine 0 is 1. So, that will imply c1 is going to be 0. Is it okay?

So, therefore, now the second condition is y equals to 0 equals to y at the point pi, which is equals to c2 times sin mu pi. That is what you have, right? Now you see, is it okay? Because c1 is 0, right? So the only thing which is remaining is c2 times sin pi x. So basically now y equals to c2 times y pi x and we satisfy y at the point pi is 0.

So basically $c_2 \sin \mu \pi$ is going to be 0. Is it okay? Now, of course μ is non-zero, yes? So $\sin \mu \pi$ is not going to be 0, right? Generally speaking, c_2 , let us say c_2 .

So here what we have is $c_2 \sin \mu \pi = 0$. okay now if c_2 is 0 see if c_2 is 0 c_1 is 0 c_2 is 0 then we have what we have is a trivial solution in that case okay we do not want previous solution because that's not a interesting yes right okay we want non-trivial solution so if so we have trivial solution if c_2 is 0 we have trivial solution which we don't want trivial solution okay so If c_2 is not 0, what happens? If c_2 is not 0, then you have non-trivial solutions, okay? Then y of x , since sine of $\mu \pi$ is 0, okay?

If c_2 is non-0, then sine of $\mu \pi$ has to be 0. So now, what does that mean? Sine of $\mu \pi$ has to be equal to sine of $n \pi$. That's the only case when they are going to be 0, anything, z . Is it okay?

Otherwise, there is no other option, right? Okay. So, if this is the case, what does that mean? What is π ? π is nothing but n . n is in z . Is it okay?

yeah so what it means is to see if we are looking for non-trivial solutions okay positive for positive eigenvalues λ positive you see this is $\lambda = \mu^2$ so positive what positive eigenvalues exist if $\mu = n$ so basically what is the corresponding eigen functions $\mu = n$ okay so what is μ $\mu = n$ $\lambda = n^2$ so λ is μ^2 right so therefore what are the eigenvalues eigenvalues are positive, eigenvalues, okay, are given by, are given by, see, λ , eigenvalues are λ , which is μ^2 , and μ^2 is n^2 , so eigenvalues are given by n^2 , okay, n is in n , let us say, z also does not matter, right, it is n^2 , basically, huh, And what are the corresponding eigenfunctions and eigenfunctions? What are the eigenfunctions? What are the solutions of this?

See, if $\lambda = n^2$, the solution is given by, see here, after all of this, what is y of x ? y of x is nothing but $c_2 \sin \mu x$, right? That was the solution. And then That solution satisfied this y at the point π equals to 0.

Okay. So now you see if $\mu = n$, if $\mu = n$, then $y = \sin nx$. So basically for those, what is your function which satisfies? Sine of nx , right? Constant time sine of nx but constant can be 1 also.

Any constant multiple is fine. So basically it is $\sin nx$. And eigenfunctions are given by $r \sin nx$. And n is e . For now let us just say n . It is not a problem. n can be z also, but it does not matter.

So, it is basically the same thing. So, you see, these are the things. So, essentially what we can say is the eigen pair. What is an eigen pair? Eigen pair is the eigen function with its corresponding eigen vector or function.

So, eigen value with its eigen vector. So, eigen pair is $\lambda, f(x)$. Let us just write it as $\lambda, \sin nx$ okay n is in \mathbb{N} let's say or z you can put it as $z \in \mathbb{Z}$ I think it will be much appropriate okay these are the eigen pairs is it okay so let us take here to be $\lambda, \sin nx$ is in \mathbb{Z} is it okay so these are the eigen pairs eigen pair is eigen vector the eigen value the first thing is eigen value and the second part is the eigen corresponding eigen function okay right Now, so we have these positive eigenvalues.

What about negative ones? So, now case 3. If λ is, how do I put it? Let us say negative. So, minus μ^2 .

μ non-zero. Let us just take it like this. Is it okay? Then what happens? Let us just check that.

What happens? See now, $y'' - \mu^2 y = 0$, the equation turns out to be $y' - \mu y = 0$ equals to 0. Okay? We can solve this equation, right? And if you solve it, the solution which you are going to get $y(x)$ equals to $c_1 \cos \mu x + c_2 \sin \mu x$.

$\sin \mu x$, right? Yes. Oh, sorry, sorry, sorry. This shouldn't be the case. I am writing this mistake $e^{\mu x} + c_2 e^{-\mu x}$, okay?

c_1, c_2 is in \mathbb{R} here. Now, it has to satisfy those two equations again. Again, 0 equals to y at the point 0, which is equals to $c_1 e^{\mu \cdot 0} + c_2 e^{-\mu \cdot 0}$, plus c_2 times $e^{-\mu \cdot 0}$. Okay?

Handwritten notes showing the derivation of eigenvalues and eigenfunctions for the boundary value problem $y'' + \lambda y = 0$ with $y(0) = y(\pi) = 0$.

$0 = y(0) = c_1 \cos \mu \cdot 0 + c_2 \sin \mu \cdot 0 \Rightarrow c_1 = 0$
 $\therefore 0 = y(\pi) = c_2 \sin \mu \pi$

If $c_2 = 0$, we have trivial solution.
 If $c_2 \neq 0$, $\sin \mu \pi = 0 \Rightarrow \sin \mu \pi = \sin n\pi, n \in \mathbb{Z}$
 $\Rightarrow \mu = n, n \in \mathbb{Z}$

\therefore Eigenvalues are given by $n^2, n \in \mathbb{N}$ and eigenfunctions are $\{\sin nx, n \in \mathbb{Z}\}$

The eigenpairs are $\{(n^2, \sin nx) : n \in \mathbb{Z}\}$.

#3: If $\lambda = -\mu^2 (\mu \neq 0)$
 $y'' - \mu^2 y = 0 \Rightarrow y(x) = c_1 e^{\mu x} + c_2 e^{-\mu x}, c_1, c_2 \in \mathbb{R}$
 $0 = y(0) = c_1 e^{\mu \cdot 0} + c_2 e^{-\mu \cdot 0} \Rightarrow c_1 + c_2 = 0$

So, that will give us $c_1 + c_2 = 0$. Is it okay? So, that is your first equation. Let us just follow and put it. Okay? And another one, $0 = y'' + \mu y = 0$. That is there, right? So, the second one is $0 = y'' + \mu y$ at the point π , which is $c_1 e^{\mu \pi} + c_2 e^{-\mu \pi} = 0$. okay so this is two now it is quite clear that from one and two from one and two okay what you have $c_1 = c_2 = 0$ there is no other way okay so please check this part because the determinant is basically non-zero so the acceleration is only going to with the solution also only solution so basically please check this part okay so $c_1 = 0$ therefore $y(x)$ is identically equal to 0.

It is the only solution. It is the only solution. Only solution. What does that say? That says that there are no negative eigenvalues.

Is it okay? So, that will imply there does not exist any negative eigenvalue. Is it okay? Yeah. So, what did we have?

We have positive eigenvalues. Okay. Along with eigen functions which is given by sine of μx . Here. Yes.

That is what we have. Okay. And the thing is we do not have any zero eigenvalue or we do not have any negative eigenvalue. That is what. So, this is how you solve these problems.

Now, a very important part here is this. See, we have assumed. Where is it? We have assumed λ is in \mathbb{R} . We did not look at the complex formula. What happens if λ is complex?

And those things will be taken care of now. So, what we are going to do is this. We are going to define some new theory. And with the help of that theory only, I will justify why we do not have to consider the complex things. So, first of all, let us write down a definition.

definition what is definition the definition is the set of functions the set of functions okay set of functions $\phi_n(x)$ $\phi_n(x)$ uh maybe i can write it this way $n = 0, 1, 2, \dots$ each of which are piecewise continuous. For now, we are just starting with piecewise continuous. See, the definition, this definition which I am writing has nothing to do with the theory. Is it okay?

So, that is why I am just giving it for the most general case. Okay. But the thing is we are not going to need so much general cases in our, this theory. Okay. So, this is just for definition in terms of definition.

So, the most general way of putting it. Which are piecewise continuous in an infinite or finite set. Okay. Infinite set. or finite or finite interval α β interval α β okay now is said to be is said to be orthogonal orthogonal if oh sorry with respect to $r(x)$

with respect to a non-negative function $r(x)$ if ϕ_m ϕ_n
The inner product of those two. We will call it as inner product of ϕ_m and ϕ_n . Given two functions, the inner product will depend like this. $\int_{\alpha}^{\beta} \phi_m(x) \phi_n(x) r(x) dx$. This has to be 0.

Is it okay? For all, $m \neq n$. Is it okay? And, $\int_{\alpha}^{\beta} \phi_n^2(x) r(x) dx$ is non-zero for all n . Yes. See, the thing is, if those two conditions hold, okay, this r , of course, is called, as I told you, this is called the weight function.

Weight function. Okay. So, if these two conditions hold, then we call, you know, the set, the ϕ_n set is a orthogonal set. Is it okay? Orthogonal set.

Of course, if this non-zero, it is the integral $\int_{\alpha}^{\beta} \phi_n^2(x) r(x) dx$ is non-zero, right? If it is the 1, then we call it an orthonormal set. Okay. So, remark. Remark.

If $\int_{\alpha}^{\beta} \phi_n^2(x) r(x) dx = 1$ for all n , then we call it a, then the set ϕ_n of x in n is called orthonormals. It's called orthogonal. Is this okay? Right?

That's just the definition. Now, you see one small detail which we need to understand here is this. See, for something like this to happen, the integral from α β $r(x) \phi_n^2(x) dx$ is summable, right? Yes. For something like this to happen, we will assume that $r(x)$ only has a finite number of zeros.

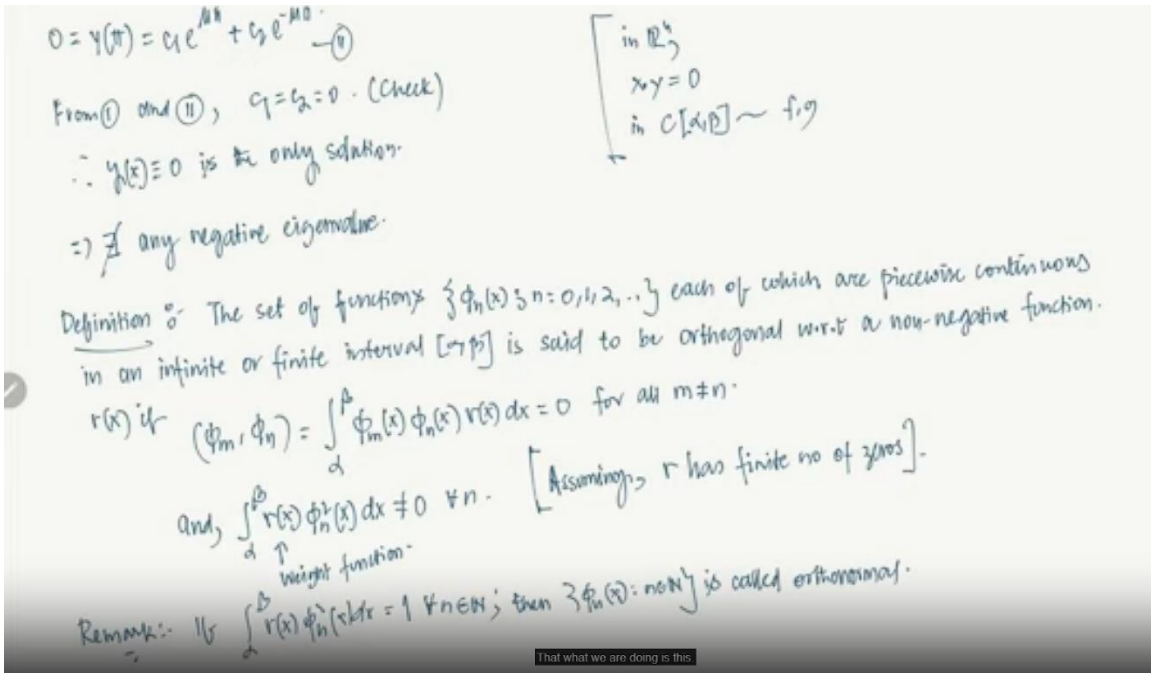

So, this is assumed. Assuming, let me put it this way. Assuming, See if you remember, maybe we have assumed that r is non-negative function, right? But we did not assume.

Maybe I can, so okay. Assuming r has finite number of zeros. Finite number of zeros. Is it okay? Now, what is the idea?

See, basically what is happening is this. Let us say in \mathbb{R}^n , I will give you some motivation. In \mathbb{R}^n , what happens is this, two functions, two points, vectors x and y , they are, I mean, orthogonal to each other, $x \cdot y$, basically they are perpendicular to each other if $x \cdot y$ is zero. So in \mathbb{R}^n what is the inner product? Inner product is given by $x \cdot y$. That's the inner product.

Basically the dot product. Now let's say in a space like this. Let's say C of alpha beta. This sort of set. You have two functions f and g .

And we say they are perpendicular to each other. But how are you going to define that perpendicular to each other path? That what we are doing is this. Basically, we are defining it as the inner product of f and g is given by integral $fg \, dx$. Is it okay?

And then if that is 0, then we call it an orthogonal. So basically this is just a generalization. In a vector space, finite dimensional vector space \mathbb{R}^n , if you have to define the inner product, you define it like a dot product $x \cdot y$, which is your usual thing. But in a vector space here, we can define, we can think of it as an inner product space. And what is the inner product?

It is given by integral $f g \, dx$. There can be others also, but this is the inner product which we are basically going to assume. Is it okay? Great. So, orthogonal set, orthonormal set. Clear?

Right. Now, the thing is this. See, question is, question. Does there exist orthonormal set? I mean, orthonormal, orthogonal is okay.

So, but does there exist one? Can you show there is one? So, you see, the thing is, let us look at this thing. The thing, sine of nx . n in n in n or $n z$ it's not a big issue but n in n for now let's just assume that huh so this set let's say call it the set a okay you see a is we are we will you know prove that this is the orthogonal set is it okay

And what is this orthogonal set? It is orthogonal somewhere. See, we say that two vectors, let us say $1, 0$ and $0, 1$, they are orthogonal to each other. Those two vectors are in some space, in some vector space, that is in \mathbb{R}^2 . Here, they are orthogonal set, let us say, in C^∞ also you can put if you want, but let us just put it as C^1 .

C^1 of, let us say, \mathbb{R}^2 . minus π to π or 0 to π also 0 to π let's just say 0 to 5 so basically in this state they are orthogonal okay right so how do you prove something like this so in this case what you have to do α to β okay R in this case is 1 . So, it is orthogonal with respect to the weight function R , which is identically equals to 1 . See, R has to be non-negative.

That is the only condition and it has to have finite number of zeros. R is 1 . If R is 1 , all of those conditions are satisfied. So, this is the orthogonal set with respect to the weight function 1 . So, how do you prove it?

Sine $n x$ times sine $m x$ dx . Okay, now, of course, you can do this integration. So please check that this is going to be 0 if m not equals to n . Okay, so this you have to check it yourself. It is basically integration, very, very easy stuff. Okay, and you can actually show that, I mean, the integral from n moreover, and integral α to β sine square $n x$ dx .

$n x$ dx sorry i should write 0 to π and not α to β i should write 0 to π 0 to π and again 0 to π sine square $n x$ dx this is going to be most probably π okay so please check this point okay you have to check it for all n for all any it is So, what does it give you? It gives you that this is a is orthogonal set. It is an orthogonal set with respect to the weight function r . So, in C^1 of $0, 1$ with respect to the weight function, weight function 1 , function $w x$ identically equals to 1 . Is it okay?

That is just, I mean, one of the, you know, examples of orthogonal Okay. Now, the important part is this. There are some theorems which we need to prove. And these are very, very important theorems.

Okay. So, the first theorem. These are the properties of regular term-label boundary value problem. Okay. The first theorem.

So, what is the first theorem? The eigenvalues. The eigenvalues of a Regular. Stumbly wheel.

Boundary value problem. I will write it like this. So please understand that. This is just a shortcut. I don't want to write the whole thing down all the time.

And what is the problem? Star. Yes. R simple. R simple.

What does it mean? Let's just understand what does it mean. It means that if. That is. If λ is an eigenvalue.

Is an eigenvalue. Okay. And ϕ_1 of x and ϕ_2 of x . Okay. Are the corresponding eigenfunctions. Are corresponding eigenfunctions.

So, you do realize that eigenfunctions for one particular eigenvalue is never going to be unique, right? Because if ϕ is an eigenfunction constant and ϕ is also going to be an eigenfunction. Is it okay? So, ϕ_1 and ϕ_2 , let us say there are two corresponding eigenfunctions for a given eigenvalue λ . What you can show is then ϕ_1 and ϕ_2 are linearly independent.

So they cannot be linearly dependent. Linearly. Sorry they are linearly dependent. So they cannot be linearly independent. So they are linearly independent.

So basically dependent. So basically what it means is ϕ_1 has to be a constant time ϕ_2 . There cannot be two extremely different functions which are like linearly independent. So what is the proof? Proof.

Now you see that ϕ_1 and ϕ_2 are both solutions, right? So ϕ_1 and ϕ_2 are both solutions. Solutions of what are these solutions of the solutions of star with λ with λ . right so you know this equation if you write it with λ where is the equation sorry uh where is the equation i wrote somewhere no star if we write λ let's say λ is an eigenvalue then ϕ_1 and ϕ_2 both satisfies this equation is it okay so and with this boundary data okay so let us let me write it down that will make life much easier So, therefore, $p \phi_1' + q \phi_1 + \lambda r \phi_1 = 0$.

And also this equation is there, $p \phi_2' + q \phi_2 + \lambda r \phi_2$, this is 0. Is it okay? We have also the boundary data, right? And moreover, and you have the boundary data, ϕ_1 at the point α plus ϕ_1' at the point α is 0.

Yes? corresponding to ϕ_1 right and the same thing also holds a naught and i hope i wrote b let me just check that part so the other one is a 1 and a a naught and a 1 d naught and d 1 i wrote up so let's write down d naught and d 1 and this thing d naught ϕ_2 sorry ϕ_1 at the point β ϕ_1 at the point β plus d 1 ϕ_1' at the point β , this is 0. And

similarly here, ϕ_2 also satisfies this equation. So, a_0 times ϕ_2 at the point α plus a_1 times ϕ_2' at the point α , this is 0.

And correspondingly, $d_0 \phi_2$ at the point β plus $d_1 \phi_2'$ at the point β , this is going to be 0. Yes, so ϕ_1 and ϕ_2 , they are both the eigen functions corresponding to the eigen value λ , then all these conditions work. Is it okay? Now you see, what does this condition say? It says that the Wronskian of ϕ_1 and ϕ_2 at the point α , this is 0.

And similarly, for β also, we can say the exact same thing, okay? But there is, what it is saying is this, there exists a point α , yeah? In that interval α, β , there exists an α where the Wronskian of two functions are 0. Essentially, that will imply, the Abel theorem, if you remember, that will imply ϕ_1 and ϕ_2 , ϕ_1 and ϕ_2 , one second, oh, sorry, sorry, sorry, what am I saying? sorry i should do it in this way okay so first of all i will come to this so essentially first of all let's just look at this see first of all these two equations are there yes what is this equation if you write it down it is $L \phi_1 + \lambda \phi_1 = 0$.

This is equivalent to this. This part is equivalent to this. And this is $L \phi_2 + \lambda \phi_2 = 0$, where L of y equals to $P y' + Q y$, right? That is your L of y . So, this is fine, right? Now, you remember?

Question :- $A = \{ \sin nx ; n \in \mathbb{N} \}$
 A is orthogonal set in $C^1[0, \pi]$ w.r.t the weight function $w(x) \equiv 1$.
 $\int_0^\pi \sin mx \sin nx dx = 0$ if $m \neq n$ (check)
 and, $\int_0^\pi \sin^2 nx dx = \pi$ if $n \in \mathbb{N}$

Theorem 1 :- the eigenvalues of a RGLBVP (*) are simple; if λ is an eigenvalue and $\phi_1(x)$ and $\phi_2(x)$ are corresponding eigenfunctions; then ϕ_1 and ϕ_2 are linearly dependent.

Proof :- ϕ_1 and ϕ_2 are both solutions of (*) with λ .

$$\begin{cases} (P\phi_1')' + Q\phi_1 + \lambda\phi_1 = 0 \\ (P\phi_2')' + Q\phi_2 + \lambda\phi_2 = 0 \end{cases} \quad \text{and} \quad \begin{cases} a_0\phi_1(\alpha) + a_1\phi_1'(\alpha) = 0 ; d_0\phi_1(\beta) + d_1\phi_1'(\beta) = 0 \\ a_0\phi_2(\alpha) + a_1\phi_2'(\alpha) = 0 ; d_0\phi_2(\beta) + d_1\phi_2'(\beta) = 0 \end{cases}$$

$\Rightarrow \begin{cases} L\phi_1 + \lambda\phi_1 = 0 \\ L\phi_2 + \lambda\phi_2 = 0 \end{cases}$ where $Ly = (Py)'+Qy$.

That is your L of y. So, this is fine, right?

If this is the case, you can use Lagrange identity. You remember I told you that we are going to use Lagrange identity later on. So, we can use Lagrange here. So, using Lagrange identity, one has that this equation, from these two equations, use the Lagrange identity, you are going to get $\phi(x)$ times the Wronskian of ϕ_1 and ϕ_2 at the point x is a constant c . c is a constant.

You remember we did this. So please go back to this adjoint equation and exact equation part that video. You are going to get this thing. So this is why Lagrange identity or Green's identity also you want to call it. It does not matter but basically it is the same thing.

You integrate one part. So basically we are going to get it. Now you see this C we have to find what this C is. Is it okay? We have to find this C . C , the thing is, that is what I am trying to say.

From here, from these two equations, what do we have? We have that this is nothing but the Wronskian of ϕ_1 , ϕ_2 at the point α . This is equal to 0. Is it okay? This is what it is saying, right?

Or even this is also saying the same thing. The Wronskian of ϕ_1 , ϕ_2 at the point β is 0. This is what it is saying. Now, the thing is, if you remember... Now, P is non-zero, right?

P is non-zero given to you, okay? So, we have to find the value of C here. What happens to the value of C ? Okay. Now, since the wrong square of ϕ_1 , ϕ_2 at the point α is going to be 0, then what is C ?

So, that will imply that C has to be equals to 0. There is no other way, right? Yes? I hope this is clear. See, other theorem, ϕ_1 and ϕ_2 are both solutions of this equation, right?

So, if the Wronskian is 0 at one point, it has to be 0 everywhere, right? That is just the Apple theorem. So, basically, if that is the case, then in this case, Wronskian of ϕ_1 , ϕ_2 at any point x is going to be essentially 0. So, in that case, c has to be equal to 0 because p is assumed to be positive. You remember?

p is assumed to be positive. We have always assumed. Since p is greater than 0. So, c has to be 0. Now, if c is 0, therefore, what does it imply?

It implies that ϕ_1 and ϕ_2 are linearly dependent. I hope this is clear to you. So, what do we have for one eigenvalue if you have two different eigenfunctions? This thing. ϕ_1 and ϕ_2 , then ϕ_1 equals to c times ϕ_2 .

That is what it is saying. So, basically, the other way of saying it is that the eigenvalues are simple. So, now let us look at the second important theorem, theorem 2. What does it say? It says that you look at the set of eigenvalues λ_n , n equals to 1, 2.

So, λ_n is essentially, be the eigenvalues Eigenvalues of a regular Sturm-Liouville boundary value problem. Is it okay? These are the eigenvalues of a regular Sturm-Liouville boundary value problem. Okay.

And ϕ_n . Is it okay? ϕ_n , n equals to 1 to this β corresponding eigenfunctions. I am writing it in terms of set, but you do realize what I am trying to say. Understanding? Eigen functions.

Is it okay? Then, the set ϕ_n of x , n equals to 1 to this set, is orthogonal. is orthogonal okay in α β in α β with respect to with respect to the weight function $r(x)$ equals to zero weight function $r(x)$ equals to zero is it okay so basically what it is saying is this sorry $r(x)$ equals to one $r(x)$ equals to one Okay, so what exactly is he saying is this, you see, if you have, so if you have, let us say λ_1 , λ_2 , it goes on like, λ_n , it goes on like this, okay. Now, corresponding to λ_1 , you have ϕ_1 .

Corresponding to λ_2 , you have ϕ_2 . Corresponding to λ_n , you have ϕ_n . Now, the relation, what is the question is this? What is the relation between ϕ_1 , ϕ_2 , ϕ_n ? The relation is this. They are saying they are going to be mutually orthogonal to each other.

So, ϕ_m times ϕ_n , if you indicate it with respect to $r(x)$ equals to 1, of course, it is going to be orthogonal. okay maybe $r(x)$ is 1 not required so with respect to the weight function $r(x)$ is fine yes don't have to work $r(x)$ equals 1 also will work but the thing is generally here there is $r(x)$ we don't want it it's fine so basically what i'm trying to say is this they are orthogonal so basically it means that $\int \phi_m(x) \phi_n(x) r(x) dx$, this is going to be 0. For $m \neq n$, of course, for $m = n$, this is going to be 0. This is what he is going to say.

Now, before we prove this thing, let me tell you why this is very important. See, essentially, this equation is important in the sense that it actually gives you a set you actually see if you have a regular Sturm-Liouville boundary value problem and if you can somehow find some set of eigenvalues and eigen functions for that then that set of eigen function set will act as a set of orthogonal functions right Yes. So, if you have to somehow, let us say for some problem purposes, you have to somehow produce an orthogonal set of functions.

Yes. What do you do? You just find a regular sum level, you just construct a regular sum level boundary level problem, solve it and you will be done. Is it okay? Yes.

So, here in this theorem, this actually guarantees that you are going to get something like that. Okay. So, let us look at the proof. Proof. So let us say that let λ_k and λ_l , $\lambda_l \neq \lambda_k$ be eigenvalues and ϕ_k , ϕ_l are the corresponding eigenfunctions.

Are the corresponding. Eigen functions. Eigen functions. Of the of course the of star. So that is given of star.

Clear. Now since ϕ_k and ϕ_l are solutions. We have this equation right. $\mathcal{L}(\phi_k) = \lambda_k r(x)\phi_k$ implies $\mathcal{L}(\phi_l) = \lambda_l r(x)\phi_l$.

$\mathcal{L}(\phi_k) = \lambda_k r(x)\phi_k$ sorry. Plus $\lambda_k r(x)\phi_k = 0$. And $\mathcal{L}(\phi_l) = \lambda_l r(x)\phi_l$ plus $\lambda_l r(x)\phi_l = 0$. Is it okay?

Now, what we are going to use to is, now again same, Lagrange identity or Green's identity, which you want to call it, using Lagrange identity. I will just call it Lagrange identity. If you want, you can call it Green's identity. No issues there.

So, using Lagrange identity, you remember, you multiply this thing with ϕ_l , you multiply that thing with ϕ_k . The first with ϕ_k , ϕ_l and the second with ϕ_l and then, you know, you indicate it. You are going to get this Lagrange identity. So, what you are going to get is ϕ_l , sorry, $\lambda_l - \lambda_k$. Integral alpha to beta, $r(x)\phi_l(x)\phi_k(x) dx$. This is nothing but alpha to beta, clear? $\int \phi_l \mathcal{L}[\phi_k] - \phi_k \mathcal{L}[\phi_l] dx$, yes, minus

Using Lagrange Identity one may

$$\int_a^b \phi_l \mathcal{L}[\phi_k] - \phi_k \mathcal{L}[\phi_l] dx = C \quad (\text{constant})$$

$$\Rightarrow C = 0 \quad (\because \beta > \alpha)$$

$\therefore \phi_k$ and ϕ_l are Linearly Dependent.

Theorem 2: Let $\{\lambda_n, n=1,2,\dots\}$ be the eigenvalues of a RGLBVP and $\{\phi_n, n=1,2,\dots\}$ be the corresponding eigenfunctions. Then the set $\{\phi_n(x), n=1,2,\dots\}$ is orthogonal in $[a,b]$ w.r.t the weight function $r(x)$.

Proof: Let λ_k and λ_l ($k \neq l$) be eigenvalues and $\phi_k(x)$ and $\phi_l(x)$ are the corresponding eigenfunctions of \mathcal{L}

$$\mathcal{L}(\phi_k) = \lambda_k r(x)\phi_k(x) = 0$$

$$\mathcal{L}(\phi_l) = \lambda_l r(x)\phi_l(x) = 0$$

Using Lagrange Identity, $(\lambda_l - \lambda_k) \int_a^b r(x)\phi_l(x)\phi_k(x) dx = \int_a^b (\phi_l \mathcal{L}[\phi_k] - \phi_k \mathcal{L}[\phi_l]) dx$

$\phi_k p_2$ of ϕ_l . $d x$. Yes. Now, and what is it? See, this is again α to β . You remember that Wronskian part is there, right?

So, this is nothing but $\phi_l x$. Sorry, $p x$ is there, right? Let me write it here. p_2 of ϕ_k . Maybe it is okay. Let me write it this way.

So, you see, this is why greens, right? Direct calculation of greens. Now, if you write it properly, it will be P times the raw scale. You know, we also talked about it here. P times the raw scale.

So, basically this. So, then what you have? Therefore, λL minus λK integral α to β . $r x$, $\phi_k x$, $\phi_l x$, $d x$. This is nothing but P of x , ϕ_l of x , ϕ_k prime of x , minus ϕ_k prime of x , ϕ_k of x , sorry, ϕ_l prime of x , ϕ_l prime of x , ϕ_k of x .

$P x$ times Wronskian of $P L P k$. See, similar sort of thing we got it here also. So, exactly the same thing which I wrote here. Now, this evaluated at the point α to β . So, I have to integrate this part, right? See, integration of α to β this.

Inside this is the Wronskian part, P times Wronskian. So, I have to integrate it between α and β . Okay. So, now, you see, we have to evaluate what happens to this. Yes.

Now, let us understand this. See, since $P k$ and $V L$ satisfies the boundary data, right? $V L$ satisfies the boundary data. The boundary data.

Okay? So, what does that mean? It means that A_0 times $V K$ at the point α plus A_1 times $V K$ prime at the point α is equal to 0. And similarly, A_0 times $V L$ at the point α plus a_1 times ϕ_l prime at the point α , this is 0.

And similarly, d_0 times ϕ_k at the point β plus d_1 times ϕ_k prime at the point β is 0. And here also similar sort of thing. d_1 times ϕ_l prime at the point β is 0. So, those two conditions are satisfied. Now, you see from these two conditions, we have that $\phi_k \alpha$ ϕ_k prime of α minus ϕ_k prime of α ϕ_l of α .

This is equals to ϕ_k of β ϕ_l prime of β minus ϕ_k prime of β . ϕ_l of β this is zero right this is what we are going to get why we are going to get this can you can you understand what is happening here see the boundary is satisfied right now think about it this way this for this problem to work okay see the thing is a naught a_1 d naught d_1 this is like an arbitrary thing it is non-zero also so basically what happens is this uh these two system of equation will have solutions other than the trivial solution okay so the wrong scale has to be the corresponding coefficient matrix that has to be uh singular so basically

uh the wrong this thing the determinant has can be zero so should be zero so basically that is what i wrote it here Now, once this is there, so therefore, if you put this condition here, if you put this condition here, see what is happening is this. Basically, it means that this integral between beta to alpha, if you calculate it from here and here, we are going to get this part is 0 because p is given to be positive.

And therefore, what you have is, that will imply $\lambda L - \lambda k = \int_{\alpha}^{\beta} r(x) \phi_k(x) \phi_l(x) dx$. This has to be equals to 0. $k \neq l$. Fine. I hope this, you know, the logic behind this is fine. See, if you remember again, what is the condition here for this thing to work?

$a_0^2 + a_1^2$ is non-zero. And the condition here is $d_0^2 + d_1^2$ is not zero. What does that mean? It means that this system has a non-trivial solution. Trivial solution is of course there, but a non-trivial solution.

This system has a non-trivial solution. That is what this means. So either one of the a_0, a_1 or d_0, d_1 is non-zero. So if that has to be the case, the corresponding, you know, the coefficient matrix has to be singular. So we are getting this.

Now this is basically nothing but this particular thing. Evaluated at beta minus evaluated at alpha, which is basically 0. So, that will give us this. Is it okay? So, what does this give you?

See, λ_n and λ_k are not same. This is what we assume. λ_k and λ_l are basically not same. They are distinct eigenvalues, right? So, that will imply $\int_{\alpha}^{\beta} r(x) \phi_k(x) \phi_l(x) dx$.

This is going to be 0. Is it okay? This is going to be 0 for $k \neq m$. So, what does it mean? It means that the set $\phi_n, n=1$ to this set, this is orthogonal with respect to

The weight function $w(x)$. Is it okay? So, this is proved. Yeah. So, what did we prove? First of all, how do you produce an orthogonal set of functions?

$$\Rightarrow (\lambda_l - \lambda_k) \int_a^b r(x) \phi_k(x) \phi_l(x) dx = r(x) \left[\phi_l(x) \phi_k'(x) - \phi_l'(x) \phi_k(x) \right] \Big|_a^b$$

$\therefore \phi_k$ and ϕ_l satisfy the boundary data:-

$$\begin{aligned} \checkmark a_0 \phi_k(a) + a_1 \phi_k'(a) = 0 & ; d_0 \phi_k(b) + d_1 \phi_k'(b) = 0 \\ a_0 \phi_l(a) + a_1 \phi_l'(a) = 0 & ; d_0 \phi_l(b) + d_1 \phi_l'(b) = 0 \end{aligned} \quad \left\{ \begin{array}{l} a_0^2 + a_1^2 \neq 0 \\ d_0^2 + d_1^2 \neq 0 \end{array} \right.$$

$$\Rightarrow \phi_k(a) \phi_k'(a) - \phi_k'(a) \phi_l(a) = \phi_k(b) \phi_l'(b) - \phi_k'(b) \phi_l(b) = 0$$

$$\Rightarrow (\lambda_l - \lambda_k) \int_a^b r(x) \phi_k(x) \phi_l(x) dx = 0 \quad (k \neq l).$$

$$\Rightarrow \int_a^b r(x) \phi_k(x) \phi_l(x) dx = 0 \quad \text{for } k \neq l.$$

$\{\phi_n : n=1,2,\dots\}$ is orthogonal w.r.t. $w(x)$

You just look at the eigenvalues and corresponding eigenfunctions. The corresponding eigenfunctions of a regular Sturm-Liouville boundary value problems are going to be orthogonal. And also, what did we prove? We also showed that the eigenvalues corresponding to a regular Sturm-Liouville boundary value problems are simple. Is it okay?

Now, in the next distinct video, we are going to look at what happens when... if they are imaginary mean why not complex okay so basically what we are going to show is we are going to show that the eigenvalues of a regular Sturm-Liouville boundary value problem are always going to be real okay that is for the next video so thank you so much
