Holder Inequality and Minkowski Inequality

In the last lecture, we have discussed the concept of metric space, the definition and some of the examples of the metric space. Today, we will do few more problems on the metric space and also, an important inequality, which is known as the Minkowski inequality, as well as, the Holders' inequality will be derived. Now, these inequalities are used basically, to establish the fourth property of the, fourth condition of the metric space; that is triangular inequalities. And, as we have seen in case of \mathbb{R}^2 or may be \mathbb{R}^n , we have left that part to verify, whether the triangle inequality is satisfied or not. Now, those things can be easily proved or verified, with the help of Minkowski inequality. So, today, our concentration will be basically, on the Holders' and Minkowski inequality. Now, before going to the Holders' and Minkowski inequality, we will give one example, which is also an interesting and important, the set of all bounded functions, which is defined over the set A ; because, we have taken the l infinity, which is the set of bounded sequences.

(Refer Slide Time: 01:46)

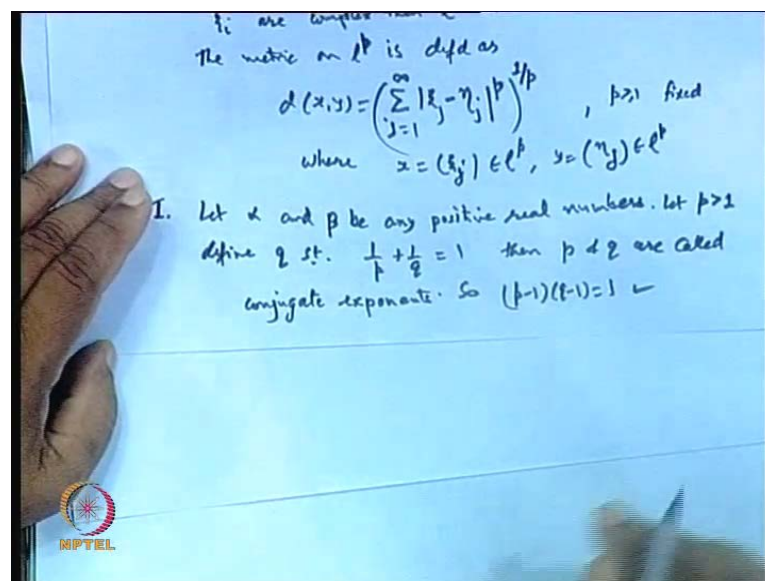

Now, bounded functions, we denote it by B of A , is the set of all functions, **set of all functions**, defined and bounded, **bounded** on a given set, **on a given set** A . And, the metric, **and metric**, we defined, **is defined** as d of x y at the supremum of mod x t minus y t , t belonging to A , **ok**, where x and y are the elements in B A and supremum is taken over all t s belonging to A . Now, this set, B A , together with this metric concept d , forms a metric space. So, this is a metric space, which can be verified easily, because d , which is defined on this, is a well defined thing, because function is defined and bounded over that closed, over this set A . So, the supremum value will be attained and we get d to be a finite, real, non negative thing.

Then, d of x y , if it is 0, then, supremum of this thing will be 0. It means, for all t , x t must be equal to y t ; and vice versa, if x , if x t equal to y t , for all t , that is, x equal to y , then, in that case, the supremum will be 0 and d of x y will be 0. Third, d of x y is d of y x is obviously true and the fourth one, can easily be seen; if I break up this part, mod of x t minus y t , this is less than equal to mod of x t minus z t plus mod of z t minus y t , where z is any other... x , y , z , these are the points in B A , set of all functions. These are the functions, defined and bounded over A . Now, take the supremum over t on the right hand side. So, it is less than equal to supremum over t , belonging to A of this difference, plus supremum of z t minus y t over t , belonging to A .

So, this part is less than equal to supremum of this, for every t belonging to A . So, left hand side is independent or left hand side depends on t , but the right hand side is independent of t , because once you take the supremum, this is a finite thing. So, take the supremum on the left hand side over t , we get, this part is less than equal to supremum of $x t$ minus $y t$, t belongs to A , plus supremum of this thing, mod $z t$ minus y , this is $z t$, this is also $z t$, sorry; so, so, $x t$ minus $z t$ plus supremum of $z t$ minus... So, this is this one; correction is here, this one. Now, this is basically, the distance between x and y , and this is the distance between x and z , this is the distance between z and y . So, triangular inequality is satisfied for this function d . Therefore, $B A$ will be a metric space. So, this will be the class of all functions, which are bounded.

Now, as a particular case, if A is replaced by the closed interval $a b$, then, this space we denote B of $a b$, and we say, it is a set of all bounded functions, defined and over the closed interval $a b$. So, we will denote, this is, $B a b$, the set of all bounded functions x , where the x is defined and bounded over the interval $a b$. And, the metric is defined in terms of the sup of this. So, this is another example of a metric space. Now, this, we have discussed the example of a sequence space; we have discuss the example of the function space; we will now go to a, another example of a sequence space, which requires the concepts of the Minkowski, which require the, the use of Minkowski and Holders' inequality.

(Refer Slide Time: 07:28)

And, that space is l^p space, which is also a metric space under a suitable metric d , where p is greater than equal to 1, p is greater than equal to 1. What is this l^p space? l^p space, l^p space is the set of those infinite sequences x_1, x_2, x_n and so on, such that, $\sum_{i=1}^{\infty} |x_i|^p$ is finite, where this x_1, x_2, x_n , these are scalar quantity. So, where x_i 's are scalars. If x_i 's are real, if x_i 's are real, then, the l^p space is said to be real space, real l^p space; and if x_i 's are complex numbers, then, we say, call l^p as complex l^p space. So, l^p is the class of those sequences x , infinite sequence x_1, x_2, x_n , such that, $\sum_{i=1}^{\infty} |x_i|^p$ is finite; that is, those infinite sequence which are l^p sequence. So, we get this one.

The metric on l^p is defined as $d(x, y) = \left(\sum_{j=1}^{\infty} |x_j - y_j|^p \right)^{1/p}$, where p is greater than equal to 1 is a fixed number. Now, the question arise, whether this definition of the metric is well defined; whether d is well defined on l^p or not; whether this series converges or not? Second one is, if it is well defined, whether this satisfy all the condition of the metric axiom or not. So, if we look this metric, the first three condition follows immediately. d is greater than equal to 0; obviously, because the mod is there. It is a real value; finiteness will be tested; finite, unless it is convergent, we cannot say this thing is finite, ok.

The finite and real, finite part will be taken care by the Minkowski inequality. Then, $d(x, y) = d(y, x)$, if I interchange the position, this will not change. $d(x, y) \geq 0$; then, obviously, individual term will be 0 and $|x_j - y_j|$ will be equal to $|y_j - x_j|$. So, $x = y$ and this, vice versa is also true. The fourth property, that is a triangle inequality, again requires the use of Minkowski inequality. So, basically, before going to test, whether this is a metric or not, we first do derive the result for these two inequalities, which are known as the Holders' inequality and Minkowski inequality. Now, here, x and y , these are the points in l^p space; $|x_j - y_j|$ and $|y_j - x_j|$, these are the point in l^p space, ok.

So, before going this, let us see the proof. So, first, we will derive an inequality. What is the result is, let α and β be any positive real number, real numbers, numbers and p and q , and let p is greater than 1; define q , such that, $\frac{1}{p} + \frac{1}{q} = 1$; then p and q are called conjugate exponents, exponents. And, obviously, when this condition is satisfied, so, we get, $\frac{p-1}{p} = \frac{1}{q}$, which can easily be seen. $p \cdot q = p \cdot \frac{p}{p-1} = \frac{p^2}{p-1}$ and immediately, we can get this result, clear. Now, based on it, we, in order inequality is...

(Refer Slide Time: 13:43)

Result I. $\alpha\beta \leq \frac{\alpha^p}{p} + \frac{\beta^q}{q}$; α, β are positive real number & $p > 1, q > 1$
 such $\frac{1}{p} + \frac{1}{q} = 1$

Obviously, $\alpha=0, \beta=0$, this inequality holds.
 Let $\alpha \neq 0, \beta \neq 0$.

Consider a function $u = t^{p-1}$
 area of the rectangle $\alpha\beta \leq \int_0^\alpha t^{p-1} dt + \int_0^\beta u^{q-1} du$

$= \left(\frac{t^p}{p}\right)_0^\alpha + \left(\frac{u^q}{q}\right)_0^\beta = \frac{\alpha^p}{p} + \frac{\beta^q}{q}$

Result II (Hölder's Inequality): Let $x = (x_j) \in \ell^p$ and $y = (y_j) \in \ell^q$. Then
 $\sum_{j=1}^{\infty} |x_j y_j| \leq \left(\sum_{k=1}^{\infty} |x_k|^p\right)^{1/p} \left(\sum_{m=1}^{\infty} |y_m|^q\right)^{1/q}$, where $p > 1$ & $\frac{1}{p} + \frac{1}{q} = 1$

Result. Alpha and beta be any two positive number, then, alpha into beta is less than equal to alpha to the power p by p plus beta to the power q by q, where alpha, beta are positive real numbers and p is greater than 1; q is such that, 1 by p 1 by q is 1. Now, obviously, for alpha is 0 and beta is 0, this inequality hold, holds; it is true, obviously. So, let alpha is not equal to 0, beta is not equal to 0. So, for general, we wanted to... So, suppose, we have a function, say, this is t, this is, say u. So, consider a function u as t to the power p minus 1. So, if we have this function, means, this is a continuous curve, may be like this, u is equal t to the power p minus 1.

Alpha and beta, this is alpha and here is, say beta. So, alpha, beta are the two positive real number. Complete the rectangle. Then, this alpha, beta denotes the area of this portion, like this, area of this portion; that is, the area 1 plus 2, 1 plus 2; these are the two areas. Now, this, alpha beta area will be... So, area of the rectangle, whose sides are alpha and beta, means, this sides are alpha and beta, O alpha, is less than equal to t to the power p minus 1 d t, 0 to alpha, 0 to, say here, alpha, plus q to the power, u to the power q minus 1, 0 to beta. Why, because, this area, alpha beta is the area of the rectangle; rectangle is, if I take this as A, this as B and this as C and this is, say D.

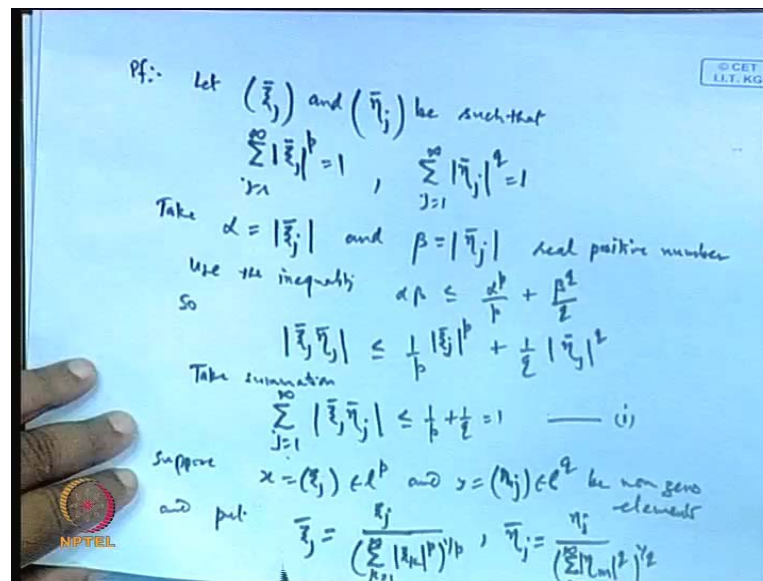

Then, this alpha beta is the area of the rectangle OABC. And, this area is less than equal to the area of this portion, say B dash, OAB dash, which is the area of this part, because the curve is, u equal to t to the power p minus 1, bounded between 0 to alpha. So, the

area will be 0 to α , t to the power $p - 1$ and if I look the function through the axis of x , in this direction, then, this portion, this portion of the curve is nothing, but t to the power, if I take here, then, t is equal to u to the power $1/p - 1$ which is as good as $q - 1$. So, this is the curve, if I look along this direction. So, this curve will be u to the power $q - 1$ and bound is 0 to β ; it varies from 0 to β . So, this area. So, 1 area plus 2 area, this one is less than equal to basically, this portion is extra, so, this one. Now, it is simple integration and when integrate and substitute the value, you get t to the power p by p under the limit 0 to α plus u to the power q by q under the limit 0 to β and that gives you α to the power p by p plus β to the power q by q , **ok**.

So, this gives you the result and which is valid for any positive real number, for β and p is greater than 1 and q is the conjugate exponent of p . The second result, which we also called, the Holders' inequality, **inequality**. What is this, Holders' inequality says, let x , which is x_i belongs to l^p and y , which is y_j belongs to l^q , where p and q they are the conjugate exponents; then, the product of these two sequence is $x_i y_i$ will be in l^1 and we have this inequality, $\sum_{j=1}^{\infty} x_j y_j$ is less than equal to **sigma**, $\sum_{k=1}^{\infty} x_k^p$ power $1/p$ plus, sorry, not plus, multiplied by, multiplied by **sigma**, $\sum_{m=1}^{\infty} y_m^q$ power $1/q$, where p and q are conjugate; p is greater than 1 and q is, such that, $1/p + 1/q = 1$. Now, this inequality is known as the Holders' inequality and this is valid for all sequences, which are in l^p , X and another sequence Y , which are in l^q .

So, the product will be in l^1 . This is a series, if this right hand side convergent, means, this will be finite. So, it basically, the product of these two sequences x_i by a coordinate y , that product will be in l^1 . So, that is one, clear. Now, let us see the proof for this first result. Proof of this result, **ok**. So, in order to prove this result, we will make use of this inequality first, that, the inequality which we have derived, $\alpha \beta$ is less than equal for α^p by p plus β^q by q , for any $\alpha \beta$ are positively n number. So, we will make use of this inequality here.

(Refer Slide Time: 22:08)

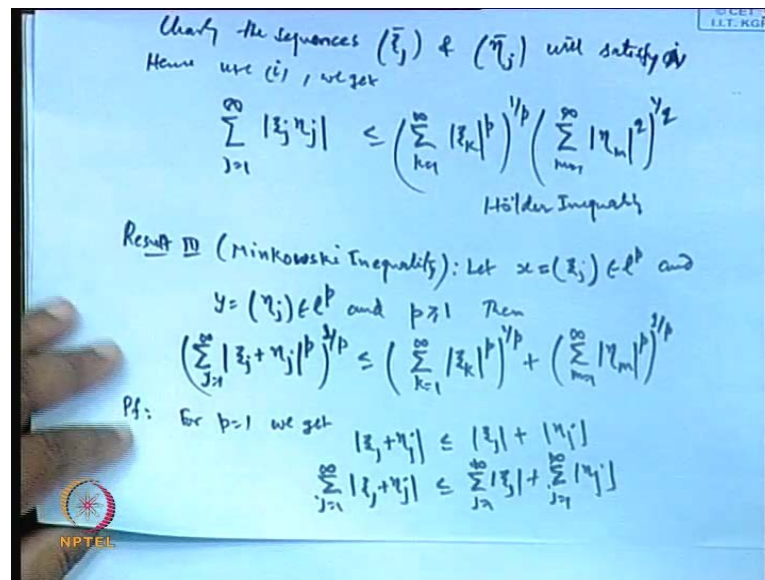

So, let us start. Let x_j and y_j be the two sequences, such that, the sum of $|x_j|^p$, j is 1 to infinity, is 1 and sum of $|y_j|^q$, j is 1 to infinity, is say, 1. Let us take these two sequences and which can be easy one. Suppose, I take x_j to be $1/2^{j/p}$ and y_j to be $1/2^{j/q}$, then, it will be 1. Sum of $|x_j|^p$ is $\sum_{j=1}^{\infty} (1/2)^j = 1$. So, such type of sequences are available and we get cancelled. Now, let us take α to be mod of x_j and β to be mod of y_j , **ok**. Now, α and β we have chosen. So, both are real, positive number. Hence, we can use this inequality, **inequality**, that is, $\alpha\beta$ is less than equal to $\alpha^p/p + \beta^q/q$. So, substitute $\alpha\beta$ here. So, we get, $|x_j y_j|$ is less than equal to $|x_j|^p/p + |y_j|^q/q$, **ok**.

Now, take the summation, **take summation**. So, sum of $|x_j y_j|$, j is 1 to infinity, is less than equal to... Now, when you take the summation, then, sum of $|x_j|^p$ is 1; sum of $|y_j|^q$ is 1. So, it will be the same as $1/p + 1/q$, that is 1. So, what we get it that, sum of $|x_j y_j|$ is 1. Let it be say 1. It means, if I choose x_j and y_j , for which **this** is true, then, it will satisfy the condition 1. Now, taking the advantage of this inequality, we are now in a position to derive the Holders' inequality. So, what we do is, suppose x , which is x_j is in l^p and y , which is y_j is in l^q , be the non-zero, **be non-zero elements, be non-**

zero elements in these spaces. And, let us say, and put x_i as x_i over σ , σ mod x_i k power p power 1 by p , where k is 1 to infinity; and, η_j bar to be η_j by σ η_m mod of this, power q , m is 1 to infinity, power 1 by q . So, if I choose the x_i j bar and η_j bar in such a way, then, obviously, this sequence x_i j bar η_j bar satisfy the condition that, σ of this thing is 1 ; because as soon as see mod, and then, σ , you will get power p ; then, it will comes out to be 1 . It means, it satisfy the condition of, earlier condition. Hence, the sequence will be satisfy this condition, must satisfy 1 also. So, we can say this type of sequence x_i j bar η_j bar must satisfy 1 .

(Refer Slide Time: 27:37)

So, clearly, the sequences, clearly, the sequences, x_i j bar and η_j bar will satisfy 1 , will satisfy 1 , or will satisfy, if this to be 1 , let it be, say, here is A . So, it will satisfy A . Hence, use 1 , i , because they satisfy i , so, we get, we get from here, when you substitute this values in i , what we get it, i is this, σ of this is one, so, write down this mod of this in σ . So, σ of this mod x_i j η_j , j equal to 1 to infinity is less than equal to, is it not, 1 , σ k equal to 1 to infinity, mod x_i k power p power 1 by p into, is it not, this into this, so, into σ m is 1 to infinity, mod of η_m power q power 1 by q ; and, that gives you the Holders' inequality. Now, one thing we observe here that, when we say the Holders' inequality, then, left hand side we are taking the summation from j equal to 1 , whereas, the right hand side the summations are taken from k and from m , and k equal to 1 to m ; so, k , with respect to, k equal to 1 to m and with respect to m , 1 to m .

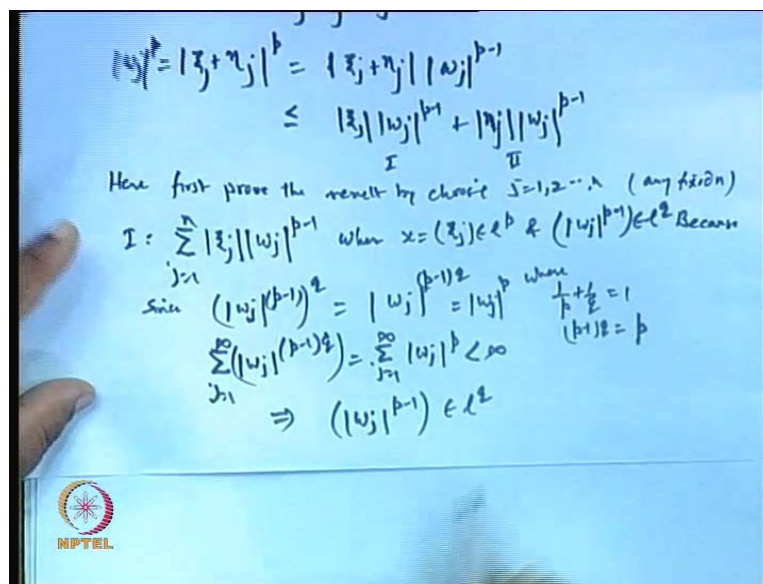

In fact, because the series, $\sum_{k=1}^{\infty} x_k^p$ is convergent $(())$, because the sequence x is in l^p ; this is the sequence x in l^p . So, this part will be finite; that is, the sequence x_k will be p th, absolutely p th summable sequence. So, this will be the absolute sum, will be finite. Similarly, η , that sequence η_m or η_i , will be in l^q , is in l^q . So, this will be finite. Therefore, when we interchange the terms, it will not affect the summation, because in case of the absolute series is, converges absolutely, summation remains the same, whether we interchange the positions of the terms. So, we get this. Therefore, it hardly matters, we, whether we take j equal to 1 to infinity, or j equal to 1 to infinity here, or maybe k is 1 to infinity or m is 1 to infinity, clear. So, this is correct. In some, one may write also, $\sum_{j=1}^{\infty} x_j^p \leq \sum_{j=1}^{\infty} x_j^p$ is less than equal to $\sum_{j=1}^{\infty} x_j^p$ by p into $\sum_{j=1}^{\infty} \eta_j^q$ by q . So, that is one, clear. Now, next result, which, third is the Minkowski inequality, **Minkowski inequality, w, Minkowski inequality**.

So, the Minkowski say, let x , this is x_j , a sequence in l^p and y , which is η_j in l^q , in an l^p and p is greater than equal to 1; then, the Minkowski inequality says that, $\sum_{j=1}^{\infty} (x_j + \eta_j)^p$ is less than equal to $\sum_{j=1}^{\infty} x_j^p + \sum_{j=1}^{\infty} \eta_j^p$ by p , **ok**. So, basically, this inequalities says that, we can write down the sum of the two sequence in terms of this inequality; x_j is one sequence; y_j is another; then, sum of the two sequence have this relation, which is valid for all p greater than 1, equal to 1; this and x and y are in... Now, this is a well defined thing; first, because, when x is in l^p , this sum will be finite; when y is in l^p , this sum will be finite.

So, the total of this sum will be finite. Therefore, sum of these series will be finite. So, if x is in l^p , y is in l^p , then, the addition of the two sequence x plus y will be in l^p . Hence, as a result, we can say that, l^p is a linear space; means, alpha time series also will be in l^p , if alpha is finite. So, it becomes a linear space and that is also a justification from this; **this** one thing. Second part is that, here, we again take k is 1 to infinity, m is $(())$, as I told you earlier, that we are free to choose the terms in any fashion; still, the sum will remain the same. So, that is why, there is no loss of generality, even if I take k equal 1 to infinity or j is 1 to infinity, like this. The proof of this.

For p is equal to 1, the inequalities follows immediately, just using the triangular inequality. For p equal to 1, we get $\text{mod } x_i + \eta_j$ is less than equal to $x_i + \text{mod } \eta_j$, because of the triangular inequality, and then, take the summation $\sum_{j=1}^{\infty}$ $\text{mod } x_i + \eta_j$ is less than equal to $\sum_{j=1}^{\infty} \text{mod } \eta_j$. So, for p equal to 1, the result follows immediately. Then, now... So, let us take the p greater than 1. So, take p greater than 1; p is greater than 1.

(Refer Slide Time: 35:32)

Now, to simplify the formula, let us take $x_i + \eta_j$ as ω_j . So, $\text{mod } x_i + \eta_j$ power p , this will be equal to, same as $\text{mod } \omega_j$ power p ; and, this can be written as $x_i + \eta_j$ into $\text{mod } \omega_j$ power p minus 1; take one of the term outside and get. Now, apply the triangular inequality. So, we get $\text{mod } x_i \text{ mod } \omega_j$ power p minus 1 plus $\text{mod } \eta_j$ into $\text{mod } \omega_j$ power p minus 1, clear. Now, this we get it. So, this is the first sum and second. Now, let it be 1 and 2; separate out this. Now, here, we will take, first for this result, here, first prove the result, ((C)) prove the result by choosing j from 1 to n ; that is the Minkowski inequality, we will just restrict upto j equal to 1 to n . And then, for n is sufficiently large, we can take it. So, where n is any fixed n , any fixed n , this is our... So, we will prove. So, let us take the, first is, the first part is, $\sum_{j=1}^n \text{mod } x_i \text{ mod } \omega_j$ power p minus 1, j is 1 to n , ok.

Now, apply that Hölder's inequality. Hölder's inequality, j equal to 1 to n , as a particular, when j is 1 to n , rest will be, say after n , is 0. So, we can use the Hölder's inequality without any problem, but only thing is, Hölder's inequality requires the product of the two sequence, where one of the sequence is in l^p , other sequence should be in l^q . So, whether this part, is it in l^q ? That is... Now, obviously, mod of w_j power p minus 1; then we raise the power q , then, this becomes mod j power p minus 1 into q ; p and q are the ((raised to it)). So, 1 by p plus 1 by q is 1 . Therefore, when we take the p minus 1, p minus 1 into q , then, what we get? Just see here, when you take 1 by p here, then, p minus 1 by p , equal to 1 by q .

So, p minus 1 into q becomes p . So, this is basically, equal to mod j power p . Now, sigma of this thing, sigma of this part, p minus 1 into q , j is 1 to infinity, this is the sigma j equal to 1 to infinity, mod w_j power p ; but w_j is a x_i plus η_j , which is in l^p , because l^p is a linear space. So, this will be in l^p . So, the sum will be finite. Therefore, this sum is finite. So, this implies that, the sequence w_j mod w_j power p minus 1 is in l^q . This implies that, mod of w_j power p minus 1 is in l^q . So, here, we take the sequence, one sequence is in l^p ; other sequence here, where x in l^p and this sequence, power p minus 1 is in l^q , because of this; because of the following reason. So, we can, without any problem, we can apply the Hölder's inequality to this. So, use the Hölder's inequality.

(Refer Slide Time: 40:44)

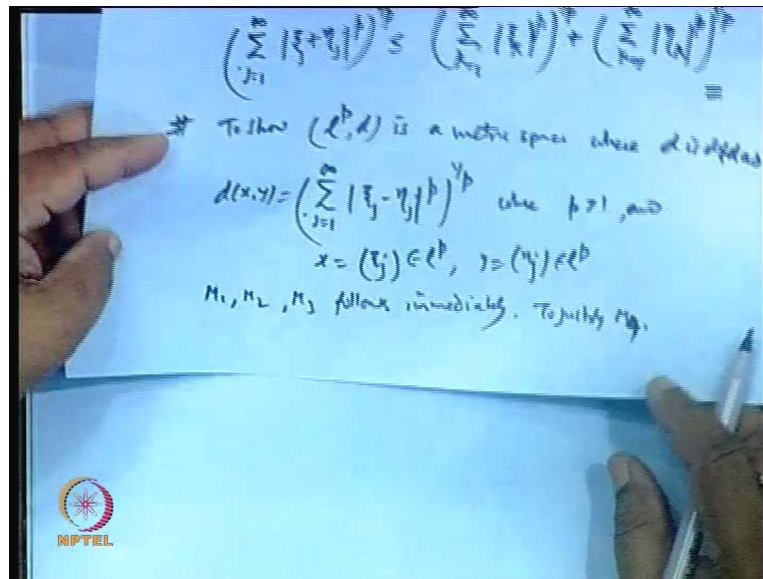

The image shows handwritten mathematical derivations on a blue background. The main derivation is as follows:

$$\begin{aligned}
 \sum_{j=1}^n |w_j|^{p-1} &= \left(\sum_{k=1}^n |z_k|^{p-1} \right)^{1/p} \left(\sum_{m=1}^n |u_m|^{p-1} \right)^{1/q} \\
 \sum_{j=1}^n |w_j|^p &\leq \sum_{j=1}^n (|z_j| + |u_j|) |w_j|^{p-1} \leq \left(\sum_{k=1}^n |z_k|^{p-1} \right)^{1/p} \left(\sum_{m=1}^n |u_m|^{p-1} \right)^{1/q} \\
 &\quad + \left(\sum_{k=1}^n |z_k|^{p-1} \right)^{1/p} \left(\sum_{m=1}^n |u_m|^{p-1} \right)^{1/q} \\
 \left(\sum_{j=1}^n |w_j|^p \right)^{1-1/p} &\leq \left(\sum_{k=1}^n |z_k|^{p-1} \right)^{1/p} + \left(\sum_{m=1}^n |u_m|^{p-1} \right)^{1/q}
 \end{aligned}$$

Use Holders' inequality.

(Refer Slide Time: 46:06)

So, we get from here is $\sum_{j=1}^n |x_j + y_j|^{p-1}$. If I use the Holders' inequality, then, it will be less than equal to $\sum_{j=1}^n |x_j|^{p-1}$, say, k is 1 to n , I am taking, power 1 by p into $\sum_{j=1}^n |y_j|$, here, $w = m$, let us be change $w = m$ power $p-1$ power q , m is 1 to n and power 1 by q , **ok**. And, this will be equal to, if I take this is $\sum_{k=1}^n |x_k|^{p-1}$ and we have seen that, $p-1$ into q is p , so, this is the $\sum_{m=1}^n |y_m|^p$, m is 1 to n , power 1 by q . So, this is the first part. Now, second part. In a similar way, for the second, we can use this $\sum_{j=1}^n |x_j|^{p-1}$, j is 1 to n . If I apply again, the Holders' inequality with the sum j equal to 1 to n , then, what we get is, this is less than equal to $\sum_{k=1}^n |x_k|^{p-1}$ into $\sum_{m=1}^n |y_m|^p$ power 1 by q , **power 1 by q** .

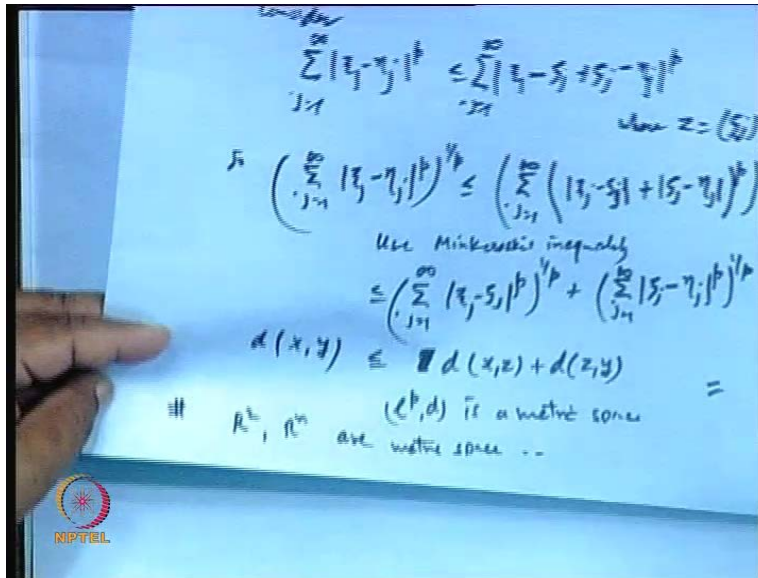

So, if I add them, then, we get these two term; addition is here. So, what we get is, **sigma** $\sum_{j=1}^n |x_j + y_j|^{p-1}$, this is $\sum_{j=1}^n |x_j + y_j|^{p-1}$, j equal to 1 to n , is less than equal to $\sum_{k=1}^n |x_k|^{p-1}$ plus $\sum_{m=1}^n |y_m|^p$, sorry, this is $\sum_{k=1}^n |x_k|^{p-1}$ plus $\sum_{m=1}^n |y_m|^p$, **is plus eta k** . So, this will be eta k , **eta k** , I am putting here, **ok**. So, plus $\sum_{k=1}^n |x_k|^{p-1}$ and this entire thing is multiplied by $\sum_{m=1}^n |y_m|^p$, because this is common. Now, this

part, if you go through the previous slides, then, basically, this is the $\sum_{j=1}^n \omega_j^p$. So, we can say, this entire thing is a greater than equal to $\sum_{j=1}^n \omega_j^p$ or $\sum_{j=1}^n \omega_j^p$, j is 1 to n , ok.

So, take this towards this side. So, take the summation and we get from here is, divide, let n tends to infinity; let n is tending to infinity. So, when we take n tends to infinity, summation will not differ and we get $\sum_{j=1}^{\infty} \omega_j^p$ and here, when you divide, $1 - \frac{1}{q}$ is less than equal to $\sum_{k=1}^{\infty} x_i^k$ power p power $\frac{1}{p}$ plus $\sum_{k=1}^{\infty} \eta_k$ power p power $\frac{1}{p}$. ok. But $1 - \frac{1}{p}$ is $\frac{1}{q}$; $1 - \frac{1}{p}$, whenever $1 - \frac{1}{q}$ is $\frac{1}{p}$. So, we get from here is... So, $\sum_{j=1}^{\infty} \omega_j^p$ power $\frac{1}{p}$ is less than equal to $\sum_{k=1}^{\infty} x_i^k$ power p power $\frac{1}{p}$ plus $\sum_{k=1}^{\infty} \eta_k$ power p power $\frac{1}{p}$, 1 to infinity, mod of η_k power p power $\frac{1}{p}$, power $\frac{1}{p}$, ok.

And, this will be nothing, but that $\sum_{j=1}^{\infty} x_i^j$ plus η_k . So, we get the inequality, $\sum_{j=1}^{\infty} x_i^j$ plus η_j power p power $\frac{1}{p}$ is less than equal to $\sum_{k=1}^{\infty} x_i^k$ power p power $\frac{1}{p}$ plus $\sum_{k=1}^{\infty} \eta_k$ power p power $\frac{1}{p}$; and, that is nothing, but the Minkowski inequality, clear. Now, this inequality also gives the guarantee that, this series is convergent. Because this is convergent, this is convergent and this is convergent. And further, it is also used to justify that l_p is a metric space under this. So, now, to show, to show l_p under that metric d is a metric space, where d is defined as, defined as $d(x, y) = \sum_{j=1}^{\infty} |x_i^j - y_i^j|$ power p power $\frac{1}{p}$, where, where p is greater than 1 or equal to 1; and x equal to x_i^j belongs to l_p ; y , which is η_j belongs to l_p . Now, how this follows is... So, first three, M_1, M_2, M_3 follows; immediately, 4, M_4 , to, to justify M_4 , what we do is, we consider this.

So, consider, mod of $x_i - y_i$ minus z_j . Now, this will be equal to, power p ; then, this is less than equal to mod $x_i - y_i$ minus, say z_j , plus z_j minus z_j , **ok**. Then, power p , **p** is greater than 1; **p** is **greater than 1**. Now, this will be... Now, take the sigma of this, j equal to 1 to infinity; take the sigma j equal to 1 to infinity. Now, take the power, where z , which is z_j belongs to l^p . Now, take the power 1 by p ; power p power 1 by p . Now, this is less than equal to sigma j equal to 1 to infinity mod of $x_i - y_i$ minus z_j plus mod of z_j minus z_j power p power 1 by p ; that is right. Now, apply the Minkowski inequality. This is as good as that two sequence $x_i, x_i + y_i$, mod of $x_i + y_i$ power p power 1 by p . So, you can use the Minkowski inequality, **inequality**. We get, this is less than equal to sigma j is 1 to infinity mod of $x_i - y_i$ minus z_j power p power 1 by p plus sigma j is 1 to infinity mod of z_j minus z_j power p power 1 by p , **ok**.

And, this will be equal to, this is, the left hand side, this is the metric d of x, y ; this is less than equal to metric, **metric** d of x, z plus metric d of z, y ; that is, the triangle inequality is followed. So, this proves the l^p space under d is a metric space. Now, as a consequence, we can also say, **as a consequence**, R^2, R^n , these are all metric spaces, under the metric defined earlier; **under the metric defined earlier**. So, we need not to go in detail, but this will follow. So, this will be.

Now, we have one more concept here, that is, the concept of the sub spaces. So, let us say, define subspace. First, let X be a metric space, **metric space** and Y is a non empty subset of X , **is a non empty subset of X** . And, suppose, **suppose**, \bar{d} is the restriction of d on Y cross Y ; what is the meaning of restriction? This is our metric space X , \bar{d} is a distance function and Y is a non empty subset of this. So, here, the elements of Y is, say y_1, y_2 , like this. Now, when we choose the points in Y and if the distance between y_1 and y_2 under the metric \bar{d} , is the same as the distance under d , then, we say, \bar{d} is the restriction of d ; that is, $\bar{d}(y_1, y_2)$ is the same as $d(y_1, y_2)$, for y_1, y_2 belongs to capital Y ; then, this is the restriction of this, clear.

So, we have this. For example, if we take this sequence. Suppose, A is the subset of, l^∞ , we have seen, l^∞ is the set of all bounded sequences and then, if we take this example, let us say, if A is the subspace of l^∞ , consisting of all sequences of 0s and 1s, **ok**. Then, the induced metric on A is nothing, but the discrete metric; because, what is the discrete metric? Discrete metric, if we take the discrete metric, say $d(x, y)$ is 0, if x is equal to y , and 1, when x is not equal to y ; it is as good as the supremum of $\min(x_i, 1 - y_i)$, **oh, sorry**, $\min(x_i, 1 - y_i)$, where x is x_i and y is y_i , **y is y_i , ok**. So, because this, these two are 0s, equal, then, it will 0; otherwise **(())**. So, discrete metric becomes the induced metric point. Thank you. That is all.
