Lecture - 34
Finite Difference Approximations to Elliptic PDEs - IV

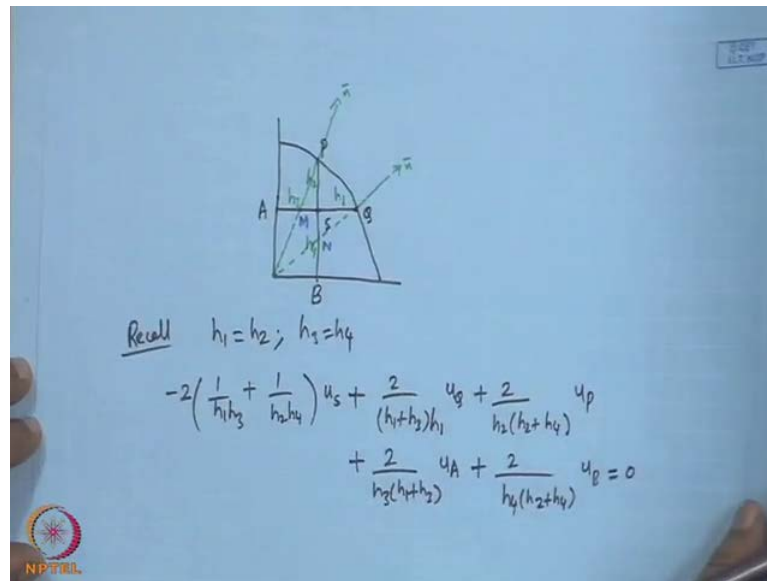

Hello, good morning. In the last class we have been discussing about non uniform grid. For example, we have to solve Laplace equation or Poisson equation inside a circle with a said d 3 or Neumann boundary conditions. So, then when we discretized, so definitely when we construct the boundary points what would happen when we fit a standard around 5 point formula. So, the boundary points will be slightly skewed towards inside. So, you would expect non uniform mesh size. So, let us solve as problem and try to see how we can handle this.

(Refer Slide Time: 01:09)

So, it is 2 d case, from the first quadrant u is 2 on x equal to 0. So, this we started in fact in the last lecture. So, when we discretized I already mentioned. So, for example, this is uniform then suppose we discretized, so then if you consider this as u_{ij} . So, then these two are having equal length, these two are having equal length. So, the step sizes are non-uniform. So, we cannot use our regular technique, we have to come up with slightly modified technique. So, we will address this.

(Refer Slide Time: 03:00)

So, now I draw this and this is a point say S Q P A and B and we this is h 1 and this is h 2 and h 3, h 4 now we take the normal through Q and it goes like that and if we take the normal to P goes like that. Now these points, this point we call n and this point we call m now we have to say we can compute these points, but when we run the standard point here it expects this and this. So, how do we handle so recall the formula. So, in this case h 1 is h 2 and h 3 is h 4 and formula which we got u at. So, this u x i y j plus u Q plus u P plus u A plus ((Refer Time: 06:03)) with this irregular grid, from the general equation which we have discussed in the last class. So, we can arrive at this so u Q u P u A and u B are involved.

(Refer Slide Time: 06:31)

$$-\frac{4}{h_1 h_3} u_s + \frac{2}{(h_1 + h_2) h_1} u_g + \frac{2}{h_1 (h_1 + h_2)} u_p + \frac{2}{h_2 (h_1 + h_2)} u_A + \frac{2}{h_3 (h_1 + h_2)} u_B = 0$$

$$\left(\frac{\partial u}{\partial n}\right)_q = \frac{u_Q - u_N}{qN} + O(qN)$$

$$\left(\frac{\partial u}{\partial n}\right)_p = \frac{u_P - u_M}{pM} + O(pM)$$

The diagram shows a quarter-circle in the first quadrant. A normal line is drawn from point P to the arc, intersecting the horizontal axis at N and the vertical axis at M. Point Q is on the arc, and point A is on the vertical axis. A dashed line connects the origin to Q.

So, this now for the case of $h_1 = h_2 = h_3 = h_4$. So, let us simplify this, this is our equation however the original problem which we defined, we have the normal prescribed. So, we have to compute, this is our Q, this is P. So, we have to compute $\frac{\partial u}{\partial n}$ in terms of these values. So, we can do that, $\frac{\partial u}{\partial n}$ at Q can be written as $\frac{u_Q - u_N}{qN}$ of course, this is up to first order. So, what is happening here, this is Q and this is N. So, $\frac{\partial u}{\partial n}$ at Q is $\frac{u_Q - u_N}{qN}$ by the distance, then P, $\frac{u_P - u_M}{pM}$. So, this is P and this point is M. So, the normal is given similarly, one can compute the value u_n as follows.

(Refer Slide Time: 09:21)

$$u_N = \frac{SN \cdot u_B + EN \cdot u_s}{h_4}$$

$$u_M = \frac{SM \cdot u_A + AM \cdot u_s}{h_3}$$

using $\left(\frac{\partial u}{\partial n}\right)_p = (\alpha^2 - \gamma^2)_p$, $\left(\frac{\partial u}{\partial n}\right)_q = (\alpha^2 - \gamma^2)_q$

$$\frac{u_Q - u_N}{qN} = (\alpha^2 - \gamma^2)_q \Rightarrow u_Q - \frac{SN \cdot u_B + EN \cdot u_s}{h_4} = (\alpha^2 - \gamma^2)_q \cdot qN$$

The diagram shows a quarter-circle with points A, B, P, M, N, Q. A normal line is drawn from P to the arc, intersecting the horizontal axis at N and the vertical axis at M. Point Q is on the arc.

We need to draw this again and again. So, then u_n is given by. So, this point is S. So, u_n is $S_N u_B$ plus $B_N u_S$ by h_4 . So, this interpolation, so let me this arm is h_1 , this arm is h_2 , this arm is h_3 and this arm is h_4 . So, these arms are h_1 is equal to h_2 , h_3 equal to h_4 . Now, this is by usual interpolation then similarly, u_M here will be $S_M u_B$. So, this is A and B plus $S_M u_A$ plus $A_M u_S$ by h_3 because $S_M u_S$ plus $A_M u_S$ by h_3 now these values. So, we have computed in terms of the existing grid points the derivatives. So, that since the derivative boundary conditions are prescribed. So, we can explicitly get algebraic equation.

Now, using, Neumann data, when we use Neumann data we have. So, this is both P and Q and we have computed earlier the normal at P and Q moreover we have computed u_n u_m for our interpolation now we combine this we combine this for combining u_Q minus u_N by Q_N this is equals to x^2 minus y^2 at Q . So, this implies u_Q minus u_N you have computed at Q .

(Refer Slide Time: 13:25)

The image shows a whiteboard with handwritten mathematical derivations. At the top right, there is a small logo for 'CET U.T.KGP'. The main content consists of several equations:

$$\frac{u_P - u_M}{PM} = (x^2 - y^2)_P$$

$$\Rightarrow \frac{u_P - \frac{S_M u_A + A_M u_S}{h_3}}{PM} = (x^2 - y^2)_P$$

Below this, it states: $u = 0$ at $x=1, y=0 \Rightarrow u_A = 2, u_B = 2$

$$\therefore \frac{u_Q - \frac{(2S_N + B_N) u_S}{h_3}}{QN} = (x^2 - y^2)_Q$$

$$\frac{u_P - \frac{(2S_M + A_M) u_S}{h_3}}{PM} = (x^2 - y^2)_P$$

At the bottom left, there is a logo for 'MPTRA'.

Similarly, we get u_P minus u_M by PM . So, this implies and we have u equals to 0 u equals to 2 on x equals to 0 y equals to 0. So, this implies u_A is 2 and u_B is 2 because both are on the axis therefore, u_Q minus. So, from the earlier one u_B is 2. So, we use the value, so u_Q and the second one u_P minus $2S_M$. So, we have got explicit algebraic equations now we have to compute these distances, which distances QN and PM .

(Refer Slide Time: 15:46)

$\tan 60^\circ = \frac{NB}{OB} \Rightarrow NB = \frac{1}{2\sqrt{3}}$
 Also $AM = \frac{1}{2\sqrt{3}}$
 Also $SQ = PS = \frac{\sqrt{3}-1}{2}$
 $\therefore h_1 = \frac{\sqrt{3}-1}{2}, h_3 = \frac{1}{2}$
 $Q = \left(\frac{\sqrt{3}}{2}, \frac{1}{2}\right), P = \left(\frac{1}{2}, \frac{\sqrt{3}}{2}\right) \Rightarrow gN = 1 - \frac{1}{\sqrt{3}}$
 $PM = 1 - \frac{1}{\sqrt{3}}$

So, let us proceed as follows for this slightly algebra routine calculation. So, from figure this is Q P N m now this is A and B therefore, $\tan \pi$ by 6 is N B by O B. So, this implies N B is similarly, A M so you can compute then also S Q equals to P S equals to. So, this you can compute therefore, this is our S therefore, h 1 and h 3. So, these are straightforward S Q P S these are equal. So, this is h 1 then similarly, S B and A S h 3 and h 4 they are half. So, we have points Q, Q is and P is P and Q.

(Refer Slide Time: 18:28)

$$-\frac{4}{\sqrt{3}-1} u_s + \frac{2}{\frac{\sqrt{3}}{2} \cdot \frac{\sqrt{3}-1}{2}} u_g + \frac{2}{\frac{\sqrt{3}-1}{2} \cdot \frac{\sqrt{3}}{2}} u_p + \frac{8}{\sqrt{3}} \cdot 2 + \frac{8}{\sqrt{3}} \cdot 2 = 0$$

$$\Rightarrow -\frac{16}{\sqrt{3}-1} u_s + \frac{8}{\sqrt{3}(\sqrt{3}-1)} u_g + \frac{8}{\sqrt{3}(\sqrt{3}-1)} u_p + \frac{32}{\sqrt{3}} = 0$$

$$u_p - \frac{2(\sqrt{3}-1)}{\sqrt{3}} - \frac{u_s}{\sqrt{3}} = -\frac{1}{2} \left(1 - \frac{1}{\sqrt{3}}\right)$$

$$u_g - \frac{u_s}{\sqrt{3}} = \frac{5}{2} \frac{\sqrt{3}-1}{\sqrt{3}}$$

$$u_p = \frac{u_s}{\sqrt{3}} + \frac{7}{2} \frac{\sqrt{3}-1}{\sqrt{3}}$$

So, accordingly Q N is and P M is, now the formula the... Algebraic equation simplifies, I am giving crude calculations you can simplify. Then further this can be simplified to the other two equations u P 2. So, this is one equation and similarly, u Q. So, you can simplify and moreover this can be simplified.

(Refer Slide Time: 20:43)

$$\frac{-16}{(\sqrt{3}-1)} u_s + \frac{9}{\sqrt{3}(\sqrt{3}-1)} u_q + \frac{8}{\sqrt{3}(\sqrt{3}-1)} u_p = -\frac{22}{\sqrt{3}}$$

$$u_p = \frac{4}{\sqrt{3}} + \frac{1}{2} \frac{(\sqrt{3}-1)}{\sqrt{3}}$$

$$u_q = \frac{4}{\sqrt{3}} + \frac{5}{2} \frac{(\sqrt{3}-1)}{\sqrt{2}}$$

$$\Rightarrow u_p = \frac{3\sqrt{3}+1}{2\sqrt{3}}, u_q = \frac{1}{2\sqrt{3}} (5\sqrt{3}-1)$$

$$u_s = 2$$

So, now we have u P u Q u S, three equations three unknowns. So, let me put them from, these one can obtain for example, solved. So, you may also try, when we have Neumann's data equals to given what is the Cauchy data, Cauchy data is you have to be obtained and this is what we have obtained the value of u. So, this is the case where you have the grid non uniform grid and you have to interpolate and also approximate the derivative. Then obtain the corresponding boundary data because we have Neumann data given therefore, the corresponding digitized data we obtain. Now let us see cylindrical coordinates how the corresponding digitization works out. Now, let us see cylindrical coordinates how the corresponding digitization works out.

(Refer Slide Time: 22:56)

Laplace equation - "Axisymmetric" - Cylindrical coordinates

$$\frac{\partial^2 u}{\partial r^2} + \frac{1}{r} \frac{\partial u}{\partial r} + \frac{\partial^2 u}{\partial z^2} = 0, \quad 0 \leq r \leq R$$
$$0 \leq z \leq c$$

$u(r,0) = f(r); \quad u(r,c) = h(r)$

$u(R,z) = g(z); \quad \frac{\partial u}{\partial r}(0,z) = 0$

discretizing the domain: $r_l = lh, \quad l = 1, 2, \dots, L$

$z_m = mk, \quad m = 1, \dots, M$

© CET
I.I.T. KGP

NPTEL

So, Laplace equation axi-symmetric cylindrical coordinates, accordingly the operator becomes I mean the equation. So, remember I have considered axi-symmetric. So, the dimension has been reduced by 1 otherwise we have the standard r ϕ z cylindrical, but because it is axi-symmetric these are independent of ϕ . Now, say in a domain we need the corresponding boundary conditions say this is f of h of r then u r z of z , say here the derivative now we have to discretized, discretizing the domain, r l is lh then z m is mk . So, then when we have this type of discretization it is like. So, this type of discretization we, r 0 to r has been discretized as lh . So, l equals to 1 , l equals to 2 in this direction. So that means l values we should literally take from minus 1 to 1 when we say l 2 minus 2 to 2 .

(Refer Slide Time: 26:26)

$$\left(\frac{\partial^2 u}{\partial n^2} + \frac{1}{n} \frac{\partial u}{\partial n} + \frac{\partial^2 u}{\partial z^2} \right) \Big|_{(r_l, z_m)} \approx a_0 u_{l,m} + a_1 u_{l+1,m} + a_2 u_{l,m+1} + a_3 u_{l,m-1} + a_4 u_{l-1,m} + \text{error}$$

$$\Rightarrow a_0 + a_1 + 2a_2 + a_3 = 0$$

$$\frac{1}{\lambda h} - (a_1 - a_3)h = 0$$

$$1 - \frac{h^2}{2} (a_1 + a_3) = 0$$

$$1 - k^2 a_2 = 0, \quad a_2 = a_4$$

$$r_l = \lambda h; \quad z_m = mk = msh, \quad k = sh$$

So, now what kind of approximation we use. So, this we discretized plus of course, error. So, we approximate, then expand the ternary expansion and then collect the coefficients and compare. So, by doing, we get the following system. So, please do yourself and make sure this system is obtained. So, now when you remember r_l is λh and z_m is mk . So, then let us have this msh that means k is taken as sh special case.

(Refer Slide Time: 28:47)

$$-2\left(1 + \frac{1}{\lambda^2}\right) u_{l,m} + \left(1 + \frac{1}{2\lambda}\right) u_{l+1,m} + \left(1 - \frac{1}{2\lambda}\right) u_{l-1,m} + \frac{1}{\lambda^2} (u_{l,m-1} + u_{l,m+1}) = h^2 f(r_l, z_m, u_{l,m}) \quad \text{--- (1)}$$

as $\lambda \rightarrow 0$, the differential equation becomes

$$2 \frac{\partial^2 u}{\partial n^2} + \frac{\partial^2 u}{\partial z^2} = f(0, z, u)$$

$$-2\left(2 + \frac{1}{\lambda^2}\right) u_{l,m} + 2(u_{l+1,m} + u_{l-1,m}) + \frac{1}{\lambda^2} (u_{l,m-1} + u_{l,m+1}) = h^2 f_{l,m} \quad \text{--- (2) for } \lambda = 0.$$

$$\frac{\partial u}{\partial n} = 0 \text{ at } n=0 \Rightarrow u_{l,m} = u_{l,m} \quad \text{--- (3)}$$

So, then the discretized equation reduces to assuming f is function of u as well now this is a equation discretized version. However as r goes to 0, so the differential equation

becomes as r goes to 0, reduced to this. Now, corresponding discretized version corresponding to this the discretized equation. However, this is as r goes to 0. So, however this is for l equals to 0. So, this is important now we have du by dr equals to 0 at r equals to 0. So, this implies the fictitious value can be eliminated because then l equals to 0, we have fictitious value from here. So, this can be eliminated, 1 2 3 with these one can obtain the solution.

(Refer Slide Time: 32:00)

$\nabla^2 u = 0, \quad 0 \leq r < 1, \quad -1 < z < 1$
 $u = 0$ on the boundary, $h = k = 1/2$
 $r_1 = 1/2, \quad z_m = m/2, \quad l = 0, \pm 1, \pm 2, \dots$
 $m = 0, \pm 1, \pm 2, \dots$
 b.c.s: $u_{l,2} = 0, \quad l = 0, 1/2, \dots$
 $u_{2,m} = 0, \quad m = 0, 1/2, \dots$
 points involved: $(0,0), (1/2,0), (0,1/2), (1/2,1/2)$

$(0,0): -6 u_{0,0} + 2(u_{1,0} + u_{0,1}) = -\frac{1}{4}$
 $(1/2,0): -4 u_{1,0} + \frac{3}{2} u_{3,0} + \frac{1}{2} u_{0,0} = -\frac{1}{4}$

© CET I.I.T. KGP
NIPTELL

So, let us see at least for a simple case the discretization and the system of equations, say we want to solve this u is 0 on the boundary and say h equals to k equals to half. So, this gives r l equals to l by 2, z m equals to m by 2 and l therefore, the boundary conditions u l 2 equals to 0, u 2 m equals to 0. This is for l 0 1 2 because you can see h equals to k equals to half. So, from 0 to r 0 to 1 therefore, we have only r 0 to 1. So, that means we are, half this is 0 and this is 1 and we should have drawn better. So, this is half and z planes. So, z planes also k is half.

So, we have to correspondingly we have to discretized therefore, u l 2 is 0 u 2 m is 0. So, these are the boundary conditions. So, then if we recall, we have these equations. So, we have to run these equations at points. So, since z is minus 1 to 1. So, the points involved are 0 0, half 0, 0 half, half half. So, at these points we have to run the equation, this equation we have to run.

So, for example, at 0 0 then half 0, so again for the remaining points these points we run and then we get a algebraic system. So, this gives some idea of discretizing the cylindrical polar coordinates of course, not arbitrary case we have considered axisymmetric case. So, let us try on stability aspects of these discretizations.

(Refer Slide Time: 36:41)

© CET
I.I.T. KGP

Accuracy and Stability

$$T_{ij} = \frac{1}{h^2} \left\{ u(x_{i-1}, y_j) + u(x_{i+1}, y_j) + u(x_i, y_{j+1}) + u(x_i, y_{j-1}) - 4u(x_i, y_j) \right\} - f(x_i, y_j)$$

$$= \frac{1}{h^2} (u_{xxxx} + u_{yyyy}) + O(h^4)$$

$E_{ij} = u_{ij} - u(x_i, y_j)$ then

$$A^h E^h = -\tau^h$$

$$A^h = \begin{bmatrix} T & I & 0 & 0 & \dots \\ I & T & I & 0 & \dots \\ & & & & \dots \\ & & & & 0 & I & T \end{bmatrix}$$

$$T = \begin{bmatrix} -4 & 1 & 0 & \dots & 0 \\ 1 & -4 & 1 & \dots & \end{bmatrix}$$

So, let us check the stability aspects accuracy and stability. So, these standard 5 point methods are discretized and the error is of the form u of $x_i - 1, y_j$ plus u of $x_i + 1, y_j$, plus u of $x_i, y_j + 1$ plus u of $x_i, y_j - 1$ minus 4. If it is laplacian and then if you have a non-homogeneous. So, this is the error, so when we expand and see this reduces to and correspondingly, if I introduce then error satisfies the following equation error satisfies $A h$ for a particular step size. So, that A has specific structure, so $A h$ has the specific structure, where T also has a specific structure. So, this we have written before. So, I am not putting completely.

(Refer Slide Time: 39:30)

For the method to be stable $\|(A^h)^{-1}\|$ is uniformly bounded as $h \rightarrow 0$

Corresponding to the matrix A^h , the (p,k) eigenvector $u^{p,k}$ has m^2 elements

$$u_{ij}^{p,k} = \sin(p\pi i h) \sin(k\pi j h)$$

and the corresponding eigenvalue is

$$\lambda_{p,k} = \frac{2}{h^2} (\cos(p\pi h) - 1 + (\cos(k\pi h) - 1))$$
$$\lambda_{1,1} = -2\pi^2 + O(h^2) \quad \text{close to } 0$$

spectral radius of $(A^h)^{-1}$: $\frac{1}{\lambda_{1,1}} \approx -\frac{1}{2\pi^2} \therefore$ stable

So, now for stability of the method, for stability of the method we need the following for the method to be stable with respect to any norm suitable norm. So, this is uniformly bounded as h goes to 0, now let us see corresponding to the matrix A , just now we have defined the p, k Eigen vector $u^{p,k}$, this has m square elements given by. So, correspond to this matrix the p, k Eigen vector this has m square elements.

The corresponding Eigen value is $\lambda_{p,k}$ $\lambda_{1,1}$ for example is which is close to 0. If you go for the spectral radius of this we have. So, this condition is satisfied therefore, stable. The method is stable. So, this general check for stability of this method. So, in the last class we started a problem on discretization with respect to polar coordinates. So, let us because we are almost concluding the elliptic equations.

(Refer Slide Time: 43:38)

example

$$\frac{\partial^2 u}{\partial x^2} + \frac{1}{x} \frac{\partial u}{\partial x} + \frac{1}{x^2} \frac{\partial^2 u}{\partial \theta^2} = 0$$

$$\frac{u_{i+1,j} - 2u_{i,j} + u_{i-1,j}}{h^2} + \frac{1}{ih} (u_{i+1,j} - u_{i-1,j})$$

$$+ \frac{1}{i^2 k^2} (u_{i,j+1} - 2u_{i,j} + u_{i,j-1}) = 0$$

$$u_{i-1,j} \left(1 - \frac{1}{2i}\right) + u_{i+1,j} \left(1 + \frac{1}{2i}\right) - 2 \left(1 + \frac{1}{i^2 k^2}\right) u_{i,j}$$

$$+ u_{i,j+1} \frac{1}{i^2 k^2} + \frac{1}{i^2 k^2} u_{i,j-1} = 0$$

So, let us see this problem and try to finish this. So, in the circular case, we are solving this and the corresponding approximated. This term then this gets simplified. So, let us introduce some notation.

(Refer Slide Time: 45:41)

$$\Rightarrow A_i u_{i-1,j} + B_i u_{i+1,j} + C_i u_{i,j} + D_i u_{i,j+1} + E_i u_{i,j-1} = 0$$

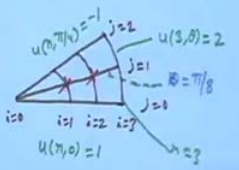

where $A_i = 1 - \frac{1}{2i}$; $B_i = 1 + \frac{1}{2i}$

$$C_i = -2 \left(1 + \frac{1}{i^2 k^2}\right) ; D_i = E_i = \frac{1}{i^2 k^2}$$

$i=1, j=1 \Rightarrow \frac{1}{2} u_{0,1} + \frac{3}{2} u_{2,1} - 2 \left(1 + \frac{64}{\pi^2}\right) u_{1,1} + u_{1,2} + u_{1,0} = 0$

$i=2, j=1 \Rightarrow \frac{3}{4} u_{1,1} + \frac{5}{4} u_{3,1} - 2 \left(1 + \frac{256}{\pi^2}\right) u_{2,1} + u_{2,2} + u_{2,0} = 0$

Solve for $u_{1,1}$ and $u_{2,1}$

$r = ih, h=1$
 $\theta = jk, k=1/2$

So, this is of the form where now let us say we consider a problem. So, we would like to solve. So, this is i equals to 0 i is 1 i is 2 i is 3 then j 0 j 1 j 2. So, let us say we have u of r 0 is 1 and say this π by 4. So, u of r π by 4 is minus 1 and say this boundary is u of 3 theta equals to 2. So, that means our domain is this, if this is the domain and this

boundary data is given. So, we have unknowns only two of them. So, let us say we want to run i equals to 1 j equals to 1 this equation.

So, this if we run equation here i equals to 1 j equals to 1 it will ask you see i equals to 1 j equals to 1. So, it will ask 2 points here 2 points there right. So, we get of course, corresponding to. So, i equals to 1 so a_i is half a_i is half $u_{0,1}$ corresponding to this plus B_i is half i is 1. So, this is 3 by 2 and $u_{2,1}$ plus c with a minus 2 1 plus. So, for these let us, if this is π by 4 corresponding to j equals to 1 what is k . So, this gives θ equals to π by 8. So, assuming k is half, so the discretization.

So, maybe we can have quick recall, r equals to $i h$ then θ equals to $j k$ and what is step size. So, here h is taken as 1 because I have given this is r equals to 3. So, this line r equals to 3 accordingly I have given, but whereas this line, θ equals to π by 8 that means k is half π by 8. So, is now we get wait let me just recall this is. So, this is π by 4 half of it, this will be 64 by π square $u_{1,1}$ plus $u_{1,2}$ plus $u_{1,0}$ because $d_i e_i$. So, this coming to be i is 1 h is 1. So, we get then i is 2 j is 1. So, again we compute the coefficients, this will be 3 by 4 $u_{1,1}$ plus i is 2. So, 5 by 4 $u_{3,1}$ and this will be $u_{2,1}$.

We know these are the points unknowns $u_{1,1}$ and $u_{2,1}$. So, what are the unknowns $u_{1,1}$ $u_{2,1}$, $u_{1,1}$, $u_{2,1}$ and remaining we substitute from the boundary data and solve for. So, this gives some idea how to discretized and obtain the solution. So, you can take maybe two points if you take one more line.

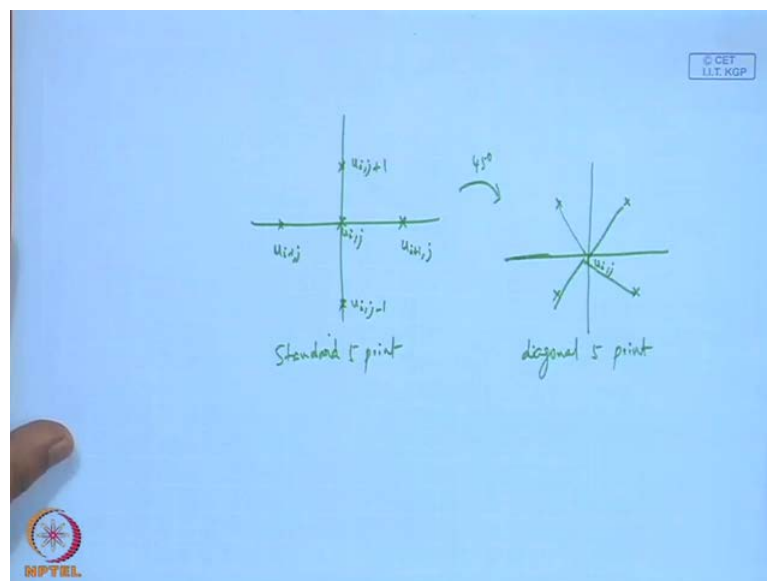

(Refer Slide Time: 53:36)

So, for example, the number of grid points increase suppose somebody takes the domain suppose you restrict your domain to this. So, your solving that means this is given u is given. So, what will be the grid points where you have to seek the solution. So, these are the four points where you have to seek the solution. So, i is 0 and this i 1, i 2 and i 3 and here j 0, j 1, j 2, j 3. So, these are the grid points, we can extend suppose if we solve it depends how many. So, accordingly the grid points will be increased see these are the grid points.

So, this is general idea how Laplace and Poisson equations are solved. So, in general for any elliptic equations, if you want to approximate using finite difference methods, we adopt this. If you consider the standard 5 point formula, you can refer some literature where if you look at you Laplace equation, it is invariate under rotation. So, if you rotate, then you get a slightly different version of A.

(Refer Slide Time: 55:38)

So, I would like to show you because many books refer that. So, this is i j and your diagonal is asking i plus 1 j , i minus 1 j , i j plus 1, i j minus 1. So, this is u i j , so if you rotate by 45 degree, then it should expect something here. So, this formula is diagonal 5 point formula. So, this is very much exists in literature. So, you can refer and try to solve the particular problem using this method, this method and compare how this method works out. So, with this we are almost done with elliptic PEDs. So, from the next lecture we move on to hyperbolic PEDs until then. Bye.
