Lecture – 59
UMVUE, Sufficiency,
Completeness

Yesterday we have introduced the criteria that among giving estimators which estimator should be preferred for example, if T_1 and T_2 have two unbiased estimators for the same parameter θ , then we will prefer T_1 over T_2 if variance of T_1 is less than or equal to variance of T_2 . In general if I am considering any 2 estimator; that means they need not be unbiased in that case we will compare the mean squared errors and the estimator with smaller mean squared error will be preferred.

(Refer Slide Time: 00:54)

Lecture 30 ①

Ex. Let X_1, \dots, X_n be a random sample from a population with mean μ and variance σ^2 .

$T_1 = \bar{X}$, $T_2 = \frac{2 \sum_{i=1}^n i X_i}{n(n+1)}$ for μ .

$$E(T_1) = \mu, \quad E(T_2) = \frac{2}{n(n+1)} \sum_{i=1}^n i E(X_i)$$

$$= \frac{2\mu}{n(n+1)} \left(\sum_{i=1}^n i \right) = \mu$$

So T_1 and T_2 are unbiased.

Let me give one example here suppose we have a random sample from a population with mean μ and variance σ^2 . Now let us consider estimators T_1 and T_2 for μ let us see. So, what is expectation of T_1 naturally it is equal to μ ; what is expectation of T_2 , you can apply the linearity property of the expectation so this becomes twice divided by n into $n + 1$, $\sum_{i=1}^n i$ expectation of X_i . Now expectation of X_i is μ , so this reduces to 2μ by n into $n + 1$ $\sum_{i=1}^n i$ is equal to 1 to n . Now this is nothing,

but n into $n + 1$ by 2 . So, this cancels out with this and you get that both T_1 and T_2 are unbiased estimator.

So, T_1 and T_2 both of them are unbiased.

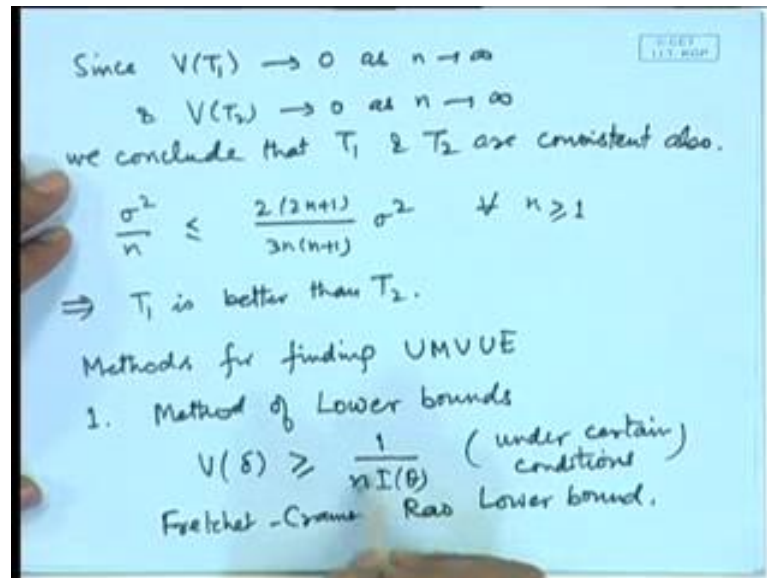

(Refer Slide Time: 01:58)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a calculation:
$$= \frac{2/n}{n(n+1)} \left(\frac{n}{2} + 1 \right) = 1/n$$
 Below this, it says "So T_1 and T_2 are unbiased." Then, the variance of T_1 is given as $V(T_1) = \frac{\sigma^2}{n}$. The variance of T_2 is given as $V(T_2) = \frac{4}{n^2(n+1)^2} \sum_{i=1}^n i^2 V(X_i)$. This is further simplified to
$$= \frac{2(2n+1)}{3n(n+1)} \sigma^2$$
 A hand holding a white marker is visible at the bottom right of the whiteboard.

Let us look at variances. So, what is variance of T_1 ? Variance of T_1 is σ^2 by n we have already shown that the variance of the sample mean is equal to σ^2 by n , let us consider the variance of T_2 . Now variance of T_2 because of the independence it becomes 4 by n^2 into $(n+1)^2$, $\sum_{i=1}^n i^2 V(X_i)$. Now variance of X_i is σ^2 and this is $\sum_{i=1}^n i^2 \sigma^2$ that is the sum of the first squares of first n integers, that is $n(n+1)(2n+1)/6$.

So, after simplification this quantity turns out to be $2(2n+1)/3n(n+1) \sigma^2$. So, now, the question is that we can also check the consistency here for example, both of them are unbiased and variance of T_1 goes to 0 as n tends to infinity, variance of T_2 also goes to 0 as n tends to infinity.

(Refer Slide Time: 03:10)

So, since variance of T_1 goes to 0 as n tends to infinity and variance of T_2 goes to 0 as n tends to infinity, we conclude that T_1 and T_2 are consistent.

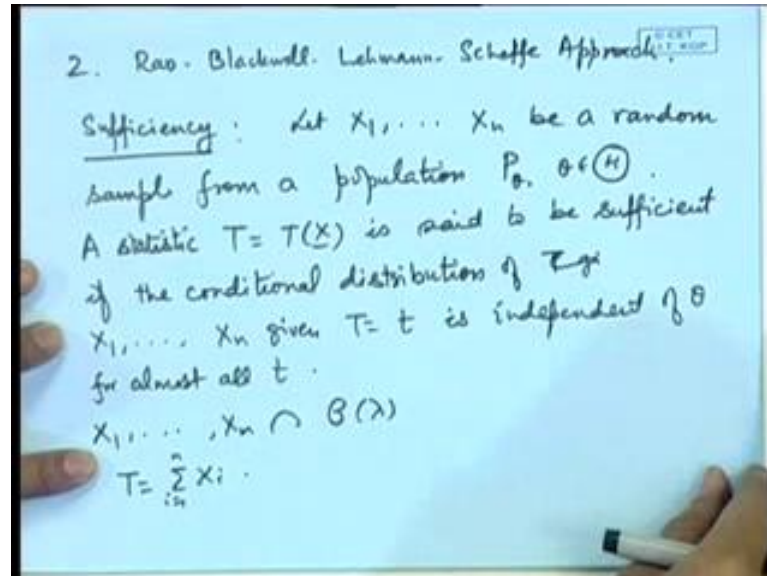

So, we have 2 estimators both of them are unbiased both of them are consistent also. So, again which one you will prefer? So, we compare the variances you can see easily that σ^2/n is less than or equal to $2(2n+1)/3n(n+1)\sigma^2$ for all n greater than or equal to 1. Actually for n is equal to 1 the 2 sides will be equal. So, this implies that T_1 is better than T_2 ; now the question comes that among a set of given estimators we can find by comparing the variances or the mean squared errors, but in the first place how to find the best among them.

So, because the total set of estimators is infinite. So, we need certain other methodology there are 2 methods for finding out the unbiased methods for finding UMVUE, one method is the method of lower bounds; under certain given conditions variance of an unbiased estimator is greater than or equal to a prescribed number it is $1/nI(\theta)$ this is under certain conditions this is called Frechet Cramer Rao lower bound.

So, if there is an estimator which will have this variance equal to this that will be naturally minimum variance and unbiased estimator, then later on the generalizations of this Frechet Cramer Rao bound have been done and we have the bounds when we have multi parameters situation when we can use higher order derivatives etcetera so, but for

application of these lower bounds certain conditions need to be satisfied and the bounds may not always be obtain.

(Refer Slide Time: 06:04)

There is another approach that is called Rao Blackwell Lehmann Scheffe approach we introduce 2 concepts that is of sufficiency and completeness so firstly, we define what is sufficiency.

So, we have the regular model that X_1, X_2, \dots, X_n random sample from a population say P_θ , θ belonging to Θ ; then a statistic T is said to be sufficient if the conditional distribution of X_1, X_2, \dots, X_n given $T = t$ is independent of θ for almost all T . Let us take an example here suppose I consider X_1, X_2, \dots, X_n follow say poisson λ distribution, let us define T to be $\sum_{i=1}^n x_i$, i is equal to 1 to n .

(Refer Slide Time: 08:08)

$$\begin{aligned}
 & P(X_1 = x_1, \dots, X_n = x_n \mid T = t) \\
 &= \frac{P(X_1 = x_1, \dots, X_n = x_n, T = t)}{P(T = t)} \\
 &= \begin{cases} \frac{P(X_1 = x_1, \dots, X_{n-1} = x_{n-1}, X_n = t - \sum_{i=1}^{n-1} x_i)}{P(T = t)}, & \sum x_i = t \\ 0, & \sum x_i \neq t \end{cases}
 \end{aligned}$$

Let us consider the conditional distribution of X_1, X_2, \dots, X_n given T is equal to t . So, this is equal to probability of X_1 is equal to x_1 and so on X_n is equal to x_n T is equal to t divided by probability of T is equal to t . Now here T is $\sum x_i$ and we know that it follows poisson $n \lambda$. So, the denominator quantity can be written; how to find out the numerator quantity we simplify this, we can write it as probability of X_1 is equal to x_1 and so on, x_{n-1} is equal to x_{n-1} and x_n is equal to $t - \sum_{i=1}^{n-1} x_i$, this is valid if $\sum x_i$ is equal to t otherwise it is defined to be 0, because it is conditional on t so for every value of T we have to determine this.

(Refer Slide Time: 09:28)

$$\begin{aligned}
 & \left\{ \frac{P(X_1 = x_1, \dots, X_{n-1} = x_{n-1}, X_n = t - \sum_{i=1}^{n-1} x_i)}{P(T = t)}, \sum x_i = t \right. \\
 & \left. 0, \sum x_i \neq t \right. \\
 & \frac{e^{-\lambda} \lambda^{x_1}}{x_1!} \dots \frac{e^{-\lambda} \lambda^{x_{n-1}}}{x_{n-1}!} \frac{e^{-\lambda} \lambda^{t - \sum_{i=1}^{n-1} x_i}}{(t - \sum_{i=1}^{n-1} x_i)!} \\
 & \frac{e^{-n\lambda} (n\lambda)^t / t!}{e^{-n\lambda} (n\lambda)^t / t!}
 \end{aligned}$$

Now, the numerator quantity can be determined because X_1, X_2, \dots, X_n are independent poisson lambda variables. So, we can substitute these values here; e to the power minus lambda, lambda to the power X_1 , by X_1 , factorial and so on and the last term will be e to the power minus lambda, lambda to the power T minus $\sum_{i=1}^n x_i$, 1 to n minus 1 divided by T minus $\sum_{i=1}^n x_i$, 1 to n minus 1 factorial and the divided by e to the power minus n lambda, n lambda to the power T divided by T factorial.

You can easily see that e to the power minus lambda term cancels out because we have n terms here and in the denominator we have e to the power minus n lambda, the powers of lambda that is lambda to the power t here and in the denominator we have lambda to the power t . So, that also cancels out.

(Refer Slide Time: 10:26)

Handwritten notes on a whiteboard:

$$= \begin{cases} \frac{t!}{x_1! \dots x_{n-1}! (t - \sum_{i=1}^{n-1} x_i)!} \cdot \frac{1}{n^t}, & t = \sum x_i \\ 0, & t \neq \sum x_i \end{cases}$$

which is independent of λ .

So $T = \sum X_i$ is a sufficient statistic

Neyman-Fisher Factorization Theorem

$$\prod_{i=1}^n f(x_i, \theta) = g(T(x), \theta) h(x)$$

$\Leftrightarrow T(x)$ is sufficient.

So, we are left with t factorial divided by x_1 , factorial and so on x_n minus 1 factorial t minus $\sum_{i=1}^n x_i$, 1 to n minus 1 factorial and 1 by n to the power t , when t is equal to $\sum_{i=1}^n x_i$ and it is equal to 0, if t is not equal to $\sum_{i=1}^n x_i$.

Now, you can see here this term does not depend upon lambda; again independent of lambda. So, we conclude that T that is $\sum X_i$ is a sufficient statistic, the role of sufficiency is quite important in a statistical inference. In fact, it means that we can generate an alternative sample say $X_1, \text{prime } X_2, \text{prime } \dots, \text{prime } X_n, \text{prime}$ given t is equal to t ; that means, whatever information about the parameter can be drawn from the sample X_1, X_2, \dots, X_n all of that is contained in $\sum_{i=1}^n x_i$; that means, there is no additional

information in X_1, X_2, \dots, X_n which is not there in $\sum_{i=1}^n X_i$, this allows us to make the data compact because we need not keep record of all the individual observations rather we keep record of only the sufficient statistics.

Now, this method of proving that $\sum_{i=1}^n X_i$ sufficient involves finding out the conditional distribution, and which may be quite cumbersome for various problems; and another things is that here we have to guess also that what would be a sufficient statistic. So, there is another result which is known as Neyman-Fisher Factorization Theorem, which allows us to figure out what will be a sufficient statistic in a given problems. I will not a state the theorem in a full form rather we look at the practical accept theorem.

We write down the joint density that is product of $f(x_i, \theta)$, i is equal to 1 to n ; this is a joint probability density function of X_1, X_2, \dots, X_n , if this can be factorized as $g(t, \theta) h(x)$, where the first term depends upon x_i is only through t and the second term is free from θ then we say that this implies and implied by the $T(x)$ is sufficient. The proof of this involves slightly major theoretic consideration, so we skip the proof, but this is a very practical way of obtaining sufficient statistics.

(Refer Slide Time: 13:43)

Examples: 1. $X_1, \dots, X_n \sim \text{Bern}(1, p)$

$$\prod_{i=1}^n f(x_i, p) = \prod_{i=1}^n \{ p^{x_i} (1-p)^{1-x_i} \}$$

$$= p^{\sum x_i} (1-p)^{n - \sum x_i} = \underbrace{\left(\frac{p}{1-p} \right)^{\sum x_i}}_{g(\sum x_i, p)} \cdot \underbrace{(1-p)^n}_{h(x)}$$

$T = \sum X_i$ is sufficient.

2. $X_1, \dots, X_n \sim U[0, \theta]$

$$\prod_{i=1}^n f(x_i, \theta) = \frac{1}{\theta^n} \mathbb{I}_{(0, \theta)}(x_i) \left\{ \prod_{i=1}^n \mathbb{I}_{(0, x_{(n)})}(x_i) \right\}$$

$$= \underbrace{\frac{1}{\theta^n} \mathbb{I}_{(0, \theta)}(x_{(n)})}_{g(x_{(n)}, \theta)} \cdot \underbrace{\prod_{i=1}^n \mathbb{I}_{(0, x_{(n)})}(x_i)}_{h(x)}$$

$X_{(n)}$ is a sufficient st.

So, let us look at the applications of this let us consider say X_1, X_2, \dots, X_n follows Bernoulli distribution. So, the joint distribution here product i is equal to 1 to n , p to the power x_i , $1 - p$ to the power $1 - x_i$, that is p to the power $\sum x_i$, $1 - p$ to the power $n - \sum x_i$, this we can write as p by $1 - p$ to the power $\sum x_i$

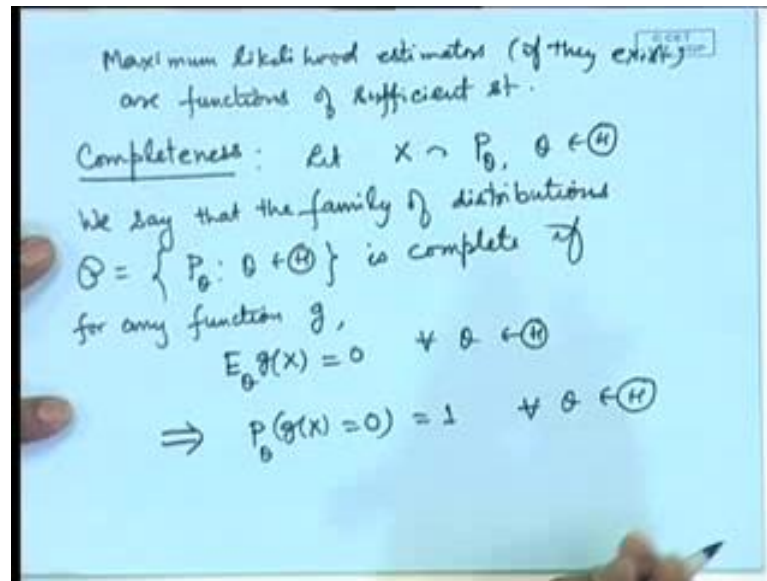

i multiplied by $1 - p$ to the power n . Now you can see here this term is a function of $\sum x_i$ and p alone and $h(x)$ we can take to be 1.

So, this proves that $\sum x_i$ is sufficient; let us look at the practical aspect of it, if we have conducted n Bernoulli trials, we may be interested and we want to draw certain inference on the proportion of the success, then you can see that $\sum x_i$ is actually the number of successes here. So, that gives the full information about p , we do not have to keep track of individual x_i . Suppose we consider say uniform distribution, then the joint density is equal to $1/\theta^n$ by θ to the power n . Now one may say that if we write like this then where is the variable coming in which will be sufficient, but this is not a complete description because for complete description we need to write down the range of the variables which is each of the x_i is from 0 to θ .

So, we can write it in the terms of indicator function, that x_i is from 0 to θ and remaining x_i they are between 0 to x_n product i is equal to 1 to $n - 1$. So, this part we can consider as g of x_n and θ and this part we can consider as $h(x)$. So, by factorization theorem we conclude that x_n is a sufficient statistic; let us also correlate with the discussion that we had in the previous lecture about the maximum likelihood estimators. The derivation of the maximum likelihood estimator involved the full probability density function or probability mass function of X_1, X_2, \dots, X_n , which we termed as the likelihood function, and that function we maximized with respect to the parameter.

Now, if you look at the factorization then this term does not play a role because if I take $1/n$ for example, then this term will be separated out and the maximization problem reduces only to the maximization of this function. So, naturally θ will become a function of $T(x)$ alone.

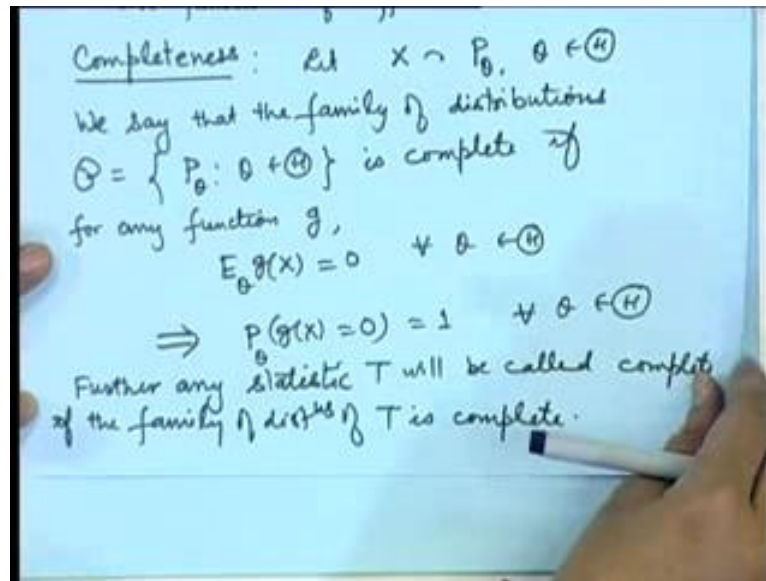

(Refer Slide Time: 17:18)

So, we conclude here that maximum likelihood estimators if they exist are functions of sufficient statistics. So, that brings as the importance of the sufficiency; that means, whatever inference we draw finally, we can restrict attention to the sufficient a statistics.

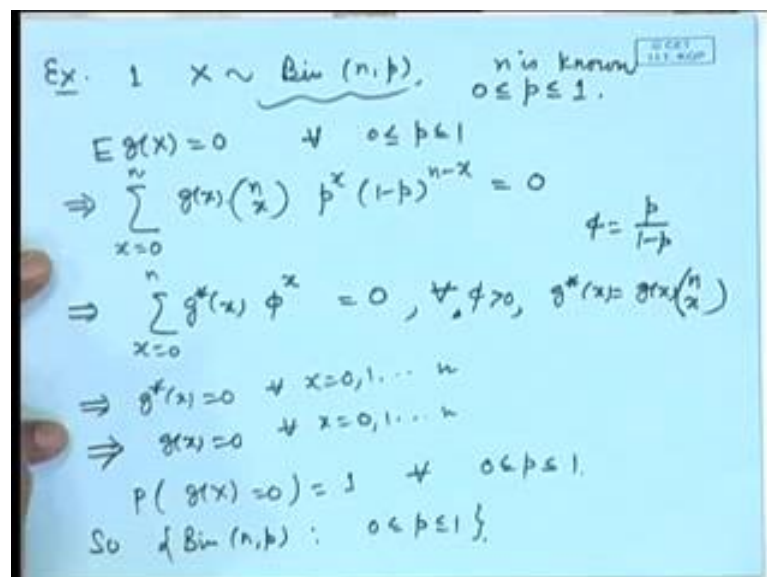

We will look at further examples of this letter; let me introduce another concept called completeness. So, let X follow a distribution say P_θ , θ belonging to Θ . So, we say that the family of distributions \mathcal{P} is equal to $\{P_\theta, \theta \in \Theta\}$ is complete if for any function g , expectation of $g(X)$ is equal to 0 for all θ implies probability of $g(X)$ is equal to 0 is equal to 1.

(Refer Slide Time: 19:08)

Further any statistic T will be called complete if the family of distributions of T is complete. So, let me give the example here and explain that what is the meaning of this, what we are saying is that whenever expectation of $g X$ is 0 that function itself is 0; that means, the only unbiased estimators of θ are θ itself; now this is a very important statement and let us see that why this is true for various distributions.

(Refer Slide Time: 20:03)

So, let us take say X follows binomial n, p where n is known and p is the parameter. Let us look at expectation of $g X$ is equal to 0, now this condition is equivalent to $g x, n \text{ c } x,$

$p^x (1-p)^{n-x}$ is equal to 0 for x is equal to 0 to n .
 We may write this as we may introduce a term called say ϕ is equal to p by $1-p$
 then this term I can write as $\sum_{x=0}^n g^* x \phi^x (1-\phi)^{n-x}$, for x equal to
 0 to n , where $g^* x$ I have written as $g x$ into $n C x$.

Now, the left hand side is a polynomial of degree n in ϕ and we are saying that it is
 vanishing for all ϕ . So, the polynomial will vanish identically on an interval provided
 all its coefficients vanish; that means, $g^* x$ is 0 for all x is equal to 0, 1 to n which
 implies that $g x$ itself is 0 for all x is equal to 0, 1 to n . So, probability that $g x$ is equal to
 0 will be 1 for all p . So, this family of binomial distributions is a complete family of
 distributions.
