Lecture- 26
Gram-Schmidt and Modified Gram-Schmidt Algorithms

Welcome. In last class we looked into Gram Schmidt process this process essentially starts with a set of independent vectors and then generate a set of orthogonal vectors from those independent vectors it is not only orthogonal vectors the vectors are also orthonormal vectors which we obtain through or Gram Schmidt process. So, in that process if we have a matrix with independent columns the matrix turns into a q matrix or the transform matrix turns into a q matrix or a matrix with normal columns in case of a square matrix we get a matrix, which is called an orthogonal matrix or matrix which has all orthonormal columns. So, in today's class we will start look into more detail on Gram Schmidt process.

And we have earlier discuss that getting orthonormal columns is important in terms of matrix solutions for example, if we have a matrix ax is equal to b and we can convert it to a form qx is equal to c where q is the orthonormal transformation of the matrix a and then we can take the c vector and project it against all of the basis orthonormal basis of q or all the columns of q and the projection will be solution $x_1 \ x_2 \ x_n$. So, the matrix solution becomes essentially match simple if we can transform a matrix from the matrix a to an orthonormal matrix q .

So, today's class we will look into more detail of the Gram Schmidt process do a quick recapitulation of what we discussed in last class and then will try to do some examples of Gram Schmidt process we will see how the Gram Schmidt algorithm should be for practical implementation purpose and the will go to qr decomposition of the matrix and see how it is useful in matrix solvers.

Gram-Schmidt process in R^3

Three basis vectors

$$C = c - (q_1^T c)q_1 - (q_2^T c)q_2$$

First form q_1 and q_2 with two vectors as it was done for R^2 .

From c , subtract the component in the plane of a and b , i.e., its projections along q_1 and q_2 . $C = c - (q_1^T c)q_1 - (q_2^T c)q_2$

The third orthonormal basis q_3 is formed by normalizing C to unit vector:

$$q_3 = \frac{C}{\|C\|}$$

So, Gram Schmidt process in real coordinates space R^3 . We have discussed this exactly, this slide in the last class; I have 3 vectors a , b and c . These 3 are independent vectors, but they are not mutually orthogonal to each other.

And the goal of Gram Schmidt process is to get a set of mutually orthonormal basis vectors. Orthonormal means, the vector should be orthogonal to each other and each of the vector should have a length equal to unity. So, we take the first vector a and divide it by its length. So, we get a unit vector along a which is the first vector in my Gram Schmidt set. The next vector q_2 which will be orthogonal to a . As well as it should be it should contain some component of b and it should have a unit length. So, what do we do? We project b on q_1 . q_1 is a unit vector.

So, the projection if I take $b \cdot q_1$, the dot product is the length of the projection of b on q_1 and then we subtract $q_1^T b$ or $b \cdot q_1$ along the direction q_1 from b . So, we get a vector B which is orthogonal to q_1 . B can be decomposed into 2 parts; one is along q_1 and the other is perpendicular to q_1 .

So, when we take the projection of b along q_1 and we subtract it from the main vector B , the new vector B is orthogonal to a and then we take the projection of B on q_1 and we subtract it from B . q_1 is along a and then we find out its length, divide the vector by its length. We get another unit vector q_2 . Now, we have the third vector C .

So, we keep on doing this can keep on doing this for any number of vectors. We project c both along q_1 and along q_2 and subtract the projection from the sorry subtract the projections from the vector C and get a vector C this C is now orthogonal to both q_1 and q_2 and we divide this C by its length and get a unit vector which is orthogonal to each other q_1 and q_2 .

So, in this process we get 3 vectors q_1, q_2, q_3 this 3 vectors are orthogonal to each other and each of them have unit length. So, we call we tell that we have arrived into an orthonormal set of vectors.

(Refer Slide Time: 04:50)

Gram-Schmidt for higher dimensional cases

This is the one idea of the whole Gram-Schmidt process, *to subtract from every new vector its components in the directions that are already settled*. That idea is used over and over again.³ When there is a fourth vector, we subtract away its components in the directions of q_1, q_2, q_3 .

Gram-Schmidt starts with independent vectors a_1, a_2, \dots, a_n and ends with orthonormal vectors q_1, q_2, \dots, q_n . At each step, it subtracts from a_j its components in the direction q_1, \dots, q_{j-1} that are already settled, as:

$$A_j = a_j - (q_1^T a_j)q_1 - \dots - (q_{j-1}^T a_j)q_{j-1}$$

The latest orthonormal vector in the set, q_j , is then obtained as: $q_j = \frac{A_j}{\|A_j\|}$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And now, for any number of vectors, this any number of independent vectors. This idea can be repeated. So, we subtract from one particular vector which is independent too few other vectors and these other vectors. We got an orthogonal set orthonormal set of vectors. So, we project these particular vectors to the previous set of orthonormal vectors and subtract the projection from these vectors. So, the remaining part is perpendicular to the already obtained set of orthonormal vectors and then we divide it by its length and get a new vector which is orthonormal to the previous set of vectors.

So, Gram Schmidt starts with independent vectors a_1, a_2, a_3 and ends up with orthonormal vectors q_1, q_2, q_n . In each steps, it subtracts from the vector a_j . It is components along the direction q_1 to q_{j-1} which are the orthonormal vectors which have already been settled as like this and then from capital it divides A by its

length to get a unit vector around this direction. So, it essentially creates number of unit vectors which are mutually perpendicular to each other and what is the number of mutually perpendicular vectors, that will be exactly the number of mutually independent vectors with which we have started.

Because, perpendicular vectors are also independent vectors. So, we take a particular vector subspace which is spanned by the independent vectors whose set was given to us initially and then, we get a new basis for that set which are mutually orthogonal vector and each has length 1 which are q_1 to q_n .

(Refer Slide Time: 06:35)

Gram-Schmidt process

If we have a set of linearly independent vectors- $v_1, v_2, v_3, \dots, v_n$, a Gram-Schmidt process will result orthonormal vectors $q_1, q_2, q_3, \dots, q_n$ as:

$u_1 = v_1$	$q_1 = \frac{u_1}{\ u_1\ }$	Where the projection operator is defined as
$u_2 = v_2 - \text{proj}_{q_1}(v_2) \rightarrow u_2 \perp q_1$	$q_2 = \frac{u_2}{\ u_2\ }$	
$u_3 = v_3 - \text{proj}_{q_1}(v_3) - \text{proj}_{q_2}(v_3)$	$q_3 = \frac{u_3}{\ u_3\ } \rightarrow u_3 \perp q_1, q_2$	$\text{proj}_{q_i}(v_j) = \frac{q_i^T v_j}{q_i^T q_i} q_i = 1 \cdot q_i$
$u_4 = v_4 - \text{proj}_{q_1}(v_4) - \text{proj}_{q_2}(v_4) - \text{proj}_{q_3}(v_4)$	$q_4 = \frac{u_4}{\ u_4\ } \rightarrow u_4 \perp q_1, q_2, q_3$	
\vdots	\vdots	
$u_k = v_k - \sum_{i=1}^{k-1} \text{proj}_{q_i}(v_k)$	$q_k = \frac{u_k}{\ u_k\ }$	

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

Now, we can write down the algorithm. We will try to write down the algorithm like that. We have set we have set of linearly independent vectors v_1 to v_n and then, we make that the first vectors we get another vector, not another vector u_1 which is equal v_1 for the first vector and unit vector along the direction u_1 is q_1 is equal u_1 by mod u_1 . For the second vector, we subtract from v_2 the projection of v_2 along q_1 . So, this becomes a vector perpendicular; that means what we get? u_2 is perpendicular to q_1 and we divide u_2 by its modulus and get sorry u_2 is perpendicular to q_1 which is already settled.

We divide u_2 by its modulus and get a unit vector q_2 . Similarly, what we do? We subtract from v_3 , its projection along q_1 and its projection along q_2 . So, what we get? A new vector u_3 which is perpendicular to both q_1 and q_2 and we divide it by the

modulus of the vector itself. So, we get an unit vector along this direction for the fourth vector. We do the same thing from u_2 , sorry this is v_3 . This will be v_3 from v_4 , this will be v_4 . From v_4 , we subtract the projection of v_4 along q_1 the projection of v_4 along q_2 and the projection of v_4 along q_3 . So, we get a new vector u_4 which is perpendicular to q_1 , q_2 and q_3 .

And we find a unit vector like that. So, that way, we can go up to k th vectors. Any number of independent vectors in a particular subspace, only the number of independent vectors cannot be more than the dimension of the subspace or if you think of real coordinates \mathbb{R}^n . We cannot have more than n number of vectors there and each vector is from each vector. We subtract its projection from the previously settled orthogonal vectors.

So, what remains is that, the component of the vector which is perpendicular to the set of orthogonal vectors. We have obtained already like for step 4. What remains as u_4 when we subtract from v_4 ? It is projection along q_1 , q_2 , q_3 what remains in u_4 is a vector which is perpendicular to both q_1 , q_2 and q_3 .

So, in that way, we have to take a vector, we have to project it along few orthogonal vectors were already settled in and we have to subtract the projections from that particular vector. What will remain with us is a vector which is perpendicular to the previous or set of orthogonal vectors and will find the unit vector along that. So, when the projector the projector operator is defined as $q_i^T v_j$ by $q_i^T q_i$ as q_i is an unit vector, this sorry as q_i is an unit vector this length. This is equal to 1 as q_i is an unit vector.

So, projection operator here will basically give as $q_i^T v_j$ into q_i . This is a dot product. So, this is a scalar quantity. It is a scalar into q_i . So, some length along the direction q_i . q_i is the unit length. So, this is the amount the magnitude of the projection along the direction of q_i , ok. So, this we have discussed in detail in last class.

(Refer Slide Time: 11:00)

Gram-Schmidt process- Example

Let us consider an independent set of vectors in R^3 :

$$v_1 = \begin{pmatrix} 3 \\ 4 \\ 0 \end{pmatrix}, v_2 = \begin{pmatrix} 0 \\ 4 \\ 3 \end{pmatrix}, v_3 = \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$$

$$q_1 = \frac{v_1}{\|v_1\|} = \frac{1}{\sqrt{25}} \begin{pmatrix} 3 \\ 4 \\ 0 \end{pmatrix} = \begin{pmatrix} 0.6 \\ 0.8 \\ 0 \end{pmatrix}$$

$$u_2 = v_2 - \text{proj}_{q_1} v_2 = \begin{pmatrix} 0 \\ 4 \\ 3 \end{pmatrix} - \begin{pmatrix} 0 & 0.6 & 0 \\ 0.6 & 0.8 & 0 \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 \\ 4 \\ 3 \end{pmatrix} = \begin{pmatrix} 0 \\ 0.6 \\ 0.8 \end{pmatrix}$$

$$q_2 = \frac{u_2}{\|u_2\|} = \frac{1}{3.842} \begin{pmatrix} -1.92 \\ 1.44 \\ 3 \end{pmatrix} = \begin{pmatrix} -0.5 \\ 0.375 \\ 0.78 \end{pmatrix}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, we now take an example we have vectors $\begin{pmatrix} 3 \\ 4 \\ 0 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 4 \\ 3 \end{pmatrix}$ and $\begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix}$. They are independent vectors.

We can quickly check and now we have to. So, this is an independent set of vectors. We can only work with an independent set of vector. If we are working on Gram Schmidt, now we have to get a set of mutually orthogonal vectors. So, the first step is very easy. You take the first vector v_1 . The first vector v_1 and get q_1 out of it, just divide v_1 by its length. So, $\begin{pmatrix} 3 \\ 4 \\ 0 \end{pmatrix}$ the length is $\sqrt{3^2 + 4^2}$ and root over of that which is $\sqrt{9 + 16}$ root which is 5 and the unit vector becomes $\begin{pmatrix} 0.6 \\ 0.8 \\ 0 \end{pmatrix}$ and we can quickly check the length is $0.6^2 + 0.8^2 = 0.36 + 0.36 = 0.72$ and if I take a square root of that, this is 1, fine.

Now, the second vector is obtained as the first vector; the second vector for second orthonormal vector, what we do? We take the second vector, also take a dot product of the second vector with q_1 and multiply with q_1 the dot product along q_1 . So, this will give as the projected vector of v_2 along q_1 and subtract it from v_2 .

So, this will be what we can write u_2 is equal to v_2 minus projection of v_2 along q_1 and what is projection of v_2 along q_1 if this is v_2 and this is q_1 ? So, this length, this length is $v_2 \cdot q_1$ and the particular vector is q_1 , sorry this is q_1 , this is not q_2 . I am sorry, 1 second.

This is q_1 , this is q_1 . So, u_2 is obtained as v_2 minus projection of v_2 along q_1 . So, this is v_2 , this is q_1 this is projection of v_2 along q_1 . Its length is $q_1^T v_2$. The vector is $q_1^T v_2$ along q_1 is a unit vector. So, along this direction, we have $q_1^T v_2$ and the sum the difference v_2 minus this is v_2 minus $q_1^T v_2$ along q_1 this vector is perpendicular to q_1 . So, from v_2 , we subtract from v_2 we subtract the first part $q_1^T v_2$ q_1 and we get v_2 minus $q_1^T v_2$ q_1 which is perpendicular to v_1 or q_1 . So, this, we get a vector which is $\begin{bmatrix} -1.92 \\ 1.443 \end{bmatrix}$.

And this vector is perpendicular to. So, I can say that this is perpendicular to q_1 . So, my q_2 must be perpendicular to q_1 . So, q_2 will be this vector y_2 divided by its modulus which gives us $\begin{bmatrix} -0.5 \\ 0.375 \\ 0.78 \end{bmatrix}$ and we can try to do $q_1^T q_2$. Here, a sorry we can try to find verify it $q_1^T q_2$ is equal to $0.6 \cdot 0 + 0.8 \cdot 0.375 + 0 \cdot 0.78$ which is 0.5 minus 0.5 into 0.6 is 0 sorry is 0.3 minus 0.3 .

0.8 into 0.375 is plus 0.3 and this is 0 into 0.78 . So, this is 0 . So, q_1 and q_2 are orthogonal. That is also verified. So now, we have to find out the third vector for the Gram Schmidt process because, there are 3 vectors. So, we will also get 3 mutually orthogonal vectors; 3 orthonormal vectors when we do the Gram Schmidt process.

(Refer Slide Time: 16:06)

Gram-Schmidt process- Example

$$u_3 = v_3 - (q_1^T v_3)q_1 - (q_2^T v_3)q_2 = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} - \begin{bmatrix} 0.6 & 0.8 & 0 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} - \begin{bmatrix} -0.5 & 0.375 & 0.78 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} - 0.6 \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix} - 0.28 \begin{bmatrix} -0.5 \\ 0.375 \\ 0.78 \end{bmatrix} = \begin{bmatrix} 0.78 \\ -0.585 \\ 0.78 \end{bmatrix}$$

$$q_3 = \frac{u_3}{\|u_3\|} = \frac{1}{1.25} \begin{bmatrix} 0.78 \\ -0.585 \\ 0.78 \end{bmatrix} = \begin{bmatrix} 0.624 \\ 0.468 \\ 0.624 \end{bmatrix}$$

So, if we look into the third vector, that is u_3 from v_3 , we subtract its projection along q_1 and its projection along q_2 . So, which is now basically u_3 is

equal to $v_3 - q_1^T v_3 q_1 - q_2^T v_3 q_2$. So, this is $v_3 - 0.6 \begin{bmatrix} 0 \\ 0.8 \\ 0 \end{bmatrix} - 0.375 \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$ along $q_1 - 0.05 \begin{bmatrix} 0.375 \\ 0.78 \\ 1 \end{bmatrix}$ with minus $0.5 \begin{bmatrix} 0.375 \\ 0.78 \end{bmatrix}$.

And this gives us $\begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$ minus this length is the projection magnitude is 0.6 the projection magnitude is 0.28 here. So, minus 0.6 into $q_1 - 0.25$ into q_2 and we get minus $0.78 \begin{bmatrix} 0.585 \\ 0.78 \end{bmatrix}$. So, this u_3 is now perpendicular to both q_1 and q_2 this is perpendicular to both the vectors q_1 and q_2 . So, we get a third vector u_3 which is perpendicular to both q_1 and q_2 .

However, we do not know whether q_3 is also with is unit vector or not. But, we can very easily verify that, we will find it is length and this the length is obviously, not 1. We divide u_3 by the length and we will get q_3 . So, $q_3 = \frac{u_3}{\|u_3\|}$ which is $\begin{bmatrix} 0.624 \\ 0.468 \\ 0.624 \end{bmatrix}$.

(Refer Slide Time: 18:12)

Gram-Schmidt process- Example

From the independent set $v_1 = \begin{bmatrix} 3 \\ 4 \\ 0 \end{bmatrix}, v_2 = \begin{bmatrix} 0 \\ 4 \\ 3 \end{bmatrix}, v_3 = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}$

An orthogonal set is formed as

$$q_1 = \begin{bmatrix} 0.6 \\ 0.8 \\ 0 \end{bmatrix}, \quad q_2 = \begin{bmatrix} -0.5 \\ 0.375 \\ 0.78 \end{bmatrix}, \quad q_3 = \begin{bmatrix} 0.624 \\ 0.468 \\ 0.624 \end{bmatrix}$$

check orthonormality
 $\|q_1\|, \|q_2\|, \|q_3\| = 1$
 $q_2^T q_1 = q_3^T q_2 = q_1^T q_3 = 0$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

So, from the independent set of vectors v_1, v_2, v_3 , we got an orthonormal set which is q_1, q_2, q_3 and we can check for the orthonormality in a sense we should check that what this the l_2 norm for both this case q_1, q_2, q_3 . This norm is equal to $\sqrt{0.36 + 0.8^2} = 1$ and $\sqrt{0.25 + 0.375^2 + 0.78^2} = 1$ and $\sqrt{0.624^2 + 0.468^2 + 0.624^2} = 1$ and $q_2^T q_1 = q_3^T q_2 = q_1^T q_3 = 0$, all these are 0.

So, this is what finally, can be checked and this satisfies that the set of vectors we obtained are orthonormal set. So, this process is essentially very simple. You only have to follow certain steps. The step is that first start with take the first vector, divide it by its length, get the first vector in the orthonormal set.

Now, for any subsequent vector in that orthonormal set, you take the linearly independent vector which is remaining with you. Now, project it with the already found out orthonormal vectors and from the vector subtract the projections. So, what we will get is the new vector which is perpendicular to the already found orthonormal set of vectors. And divide this vector by its length and you will find a unit vector along this. However, this particular process when we try to implement it in a computer program gives some issues.

(Refer Slide Time: 20:12)

Modified Gram-Schmidt

Gram-Schmidt process is often found to be numerically unstable. I.e., the final vectors produce non-zero dot products.

This is due to the **round-off error** introduced by $k-1$ projection operations at k -th step:

$$u_k = v_k - \underbrace{\text{proj}_{q_1}(v_k)}_{\perp \text{ to } q_1} - \underbrace{\text{proj}_{q_2}(v_k) - \text{proj}_{q_3}(v_k) - \dots - \text{proj}_{q_{k-1}}(v_k)}_{\text{errors}}$$

$q_k = \frac{u_k}{\|u_k\|}$

$\text{Proj}_{q_i}(u_k) = (q_i^T u_k) q_i$

This remedy is to subtract the projections of i -th vector from the next u vectors as soon as q_i is settled:

Gram Schmidt process is often found to be numerically unstable, that is when we try to check for orthonormality, the final vectors when we check that dot products, the dot products are often non 0. However, the formulation is sounds. So, we should not get a on 0 dot product. When we get q_2 , any q_i q_i plus 1 etcetera because every q_i we are finding from a vector which is perpendicular to previously settled vectors. However, what you see that there is a round off error introduced by k minus 1 projection operation at k th step.

So, what is the k th step? The vector perpendicular to already settled orthonormal vectors q_1, \dots, q_{k-1} is obtained as v_k minus its projection from v_k minus $2q_1$ minus its projection on q_2 minus 1 it is projection on q_3 etcetera. So, it is supposed that v_k minus projection of v_k along q_j projection of v_k along q_j this vector should be.

So, from v_k , we are subtracting the component of v_k which is along q_j . So, what will remain is the component which is perpendicular to q_j from vector v_k . From this vector, we are subtracting its component which is along the line. So, what will remain is a vector which is perpendicular to this line on which I am projecting it.

So, this should be perpendicular to q_j . So, if I write v_k minus projection of v_k along q_1 , this should be perpendicular to this particular part should be perpendicular to q_1 . Now, from that perpendicular part, we are subtracting few other components which are perpendicular to q_2, q_3, q_4 etcetera. However, in each subtraction or each projection what is the projection operation? Typical projection operation looks like projection of q_j on v_k variation of v_k on q_j is equal to $q_j^T v_k$ along q_j . So, this is dot product between 2 vectors.

So, it needs several multiplications and then also, when we are finding out q_3, q_2, q_3, q_k plus what we have dividing it by the modulus of this vector. So, all these calculations are introducing a round of errors. Because, all these are dealing with real numbers and if I have some number which is 3 by 7 , that has to be truncated after 8 decimal or 12 decimal or 16 decimal place in a computer program. So, we cannot write a division up to infinite digit.

Similarly, will get irrational numbers also like here. Also, because we are finding out root over of certain values and finding out length and this root of this, irrational number will also be truncated after certain values. So, as the round of error set being introduced and each step. We are introducing some of the errors. So, due to this error, this term does not remain. If there is no error from a perpendicular vector, we are subtracting something. It will still from a vector which is perpendicular to this, we are subtracting something it root of still remain perpendicular to this.

But, what we have subtracting now is introducing some error. So, the this vector is being reduced along the this reduced random. So, it can reduce at any direction.

So, it might know from perpendicular it might not remain perpendicular to q_1 . So, and it happens that this does not remain perpendicular to q_1 . So, so what we get is a set of ortho is a set of vectors which are not perpendicular to each other or as as as the product, as a final result, we get a sectors ; set of vectors, we cannot producing 0 dot product.

So, what will be the remedy? The remedy is to subtract the projections of i th vector from the next u vector as soon as q_i is settled and will check it quickly. So, once we find out this particular like this particular vector, now instead of projecting v_k on q_2 , sorry instead of projecting v_k on q_2 , will project this subtraction on q_2 and subtract it.

So, in a sense, if I have a vector like this and I project it on this q and got that this is my u . Now, instead of again projecting v on to a third vector which we are doing, here will project u on the third vector. Because, this is already an ortho perpendicular vector only projective and there that will reduce the issues due to round off error. So, the solution will be subtract the projection of i th vector from the next u vector as soon as q_i is settled.

(Refer Slide Time: 26:50)

Modified Gram-Schmidt

Compute q_k through the steps:

$$u_k^{(1)} = v_k - \text{proj}_{q_1}(v_k) \quad \text{In the step in which } q_1 \text{ is obtained}$$

$$u_k^{(2)} = u_k^{(1)} - \text{proj}_{q_2}(u_k^{(1)}) \quad \text{In the step in which } q_2 \text{ is obtained}$$

$$u_k^{(k-1)} = u_k^{(k-2)} - \text{proj}_{q_{k-1}}(u_k^{(k-2)}) \quad \text{In the step in which } q_{k-1} \text{ is obtained} \quad \text{and then find } q_k = \frac{u_k}{\|u_k\|}$$

The collection of operations are arithmetically exactly same as

$$u_k = v_k - \text{proj}_{q_1}(v_k) - \text{proj}_{q_2}(v_k) - \dots - \text{proj}_{q_{k-1}}(v_k) \quad q_k = \frac{u_k}{\|u_k\|}$$

IIT KHARAGPUR | NPTEL ONLINE CERTIFICATION COURSES

And the sorry the steps will be first find $u_{k-1} = v_k - q_1 \cdot v_k$. Once we have found q_1 , subtract its projections. Project all the vectors, all the remaining vectors and q_1 and subtract it from them.

And for k th vector, you got u_{k-1} which is v_k , the original k th vector from which the it is projection on q_1 is subtracted. Now, when you found q_2 , you subtract the projection of u_{k-1} on q_2 from u_{k-1} and get u_k and in the step when in which q_1 is obtained, you do it for k minus 1th step.

And then finally, in this step where q sorry k minus 1 is obtained and then finally, find q_k is equal to u_k by mod u_k . The collection of operations are arithmetically same as what we are doing in Gram Schmidt method only. Instead of projecting, we say for example, for finding out u_k , you project v_k on q_1 q_2 up took k minus 1 instead you project v_k on q_1 and get this as u_{k-1} .

Now, project u_{k-1} on q_2 and subtract this, then get u_k and then project u_k on q_3 and subtract it and get u_{k+1} and so on.

(Refer Slide Time: 28:42)

Modified Gram-Schmidt

Compute q_k through the steps:

$$u_k^{(1)} = v_k - \text{proj}_{q_1}(v_k) \quad \text{In the step in which } q_1 \text{ is obtained}$$

$$u_k^{(2)} = u_k^{(1)} - \text{proj}_{q_2}(u_k^{(1)}) \quad \text{In the step in which } q_2 \text{ is obtained}$$

$$u_k^{(k-1)} = u_k^{(k-2)} - \text{proj}_{q_{k-1}}(u_k^{(k-2)}) \quad \text{In the step in which } q_{k-1} \text{ is obtained} \quad \text{and then find } q_k = \frac{u_k}{\|u_k\|}$$

The collection of operations are arithmetically exactly same as

$$u_k = v_k - \text{proj}_{q_1}(v_k) - \text{proj}_{q_2}(v_k) - \dots - \text{proj}_{q_{k-1}}(v_k) \quad q_k = \frac{u_k}{\|u_k\|}$$

However, the round-off error is eliminated as u_k^j is normalized against any error made in u_k^{j-1}

And this essentially gives you a set of vectors without round of error because, round of error always eliminated when you normalize, when you orthogonalize, normalize when you orthogonalize u_k with the with another vector. So, you have a vector which has some round off error. You do a projection with another vector and subtract that part.

(Refer Slide Time: 29:10)

Modified Gram-Schmidt

Algorithm

1. For $j = 1, \dots, n$ Do:
2. Compute $r_{jj} := \|\hat{x}_j\|_2$,
3. If $r_{jj} = 0$ then Stop, else $q_j := \hat{x}_j / r_{jj}$
4. For $i = j + 1, \dots, n$, Do:
5. $r_{ji} := (x_i, q_j)$
6. $x_i := x_i - r_{ji}q_j$ ←
7. EndDo
8. EndDo

So, round off error is in a way also subtracted. It has been shown that this is the modified Gram Schmidt algorithm where basically you subtract.

So, you start with i is equal to j is equal to 1, find the length of the vector and find the unit vector. Then, you take that unit vector and take dot product of the unit vector with all other vector in that set and subtract it from all the vectors. So, in this state and then you go for 2 and do this thing. So, subtract the projection of on j th vector and in the next step, you project the remain remaining part on j plus 1th vector.

So, essentially, this is a much stable algorithm and in next class, will see that if we compare Gauss Gram Schmidt with modified Gram Schmidt in certain cases where there is some component, where round off error can be vital or there is some calculation in which round off error can be vital. For example, I am subtracting from 1 1.001. If there is no round off, it will be 0.001.

But, if there is a round off error after second decimal place, this will be 0 and division with them will give me an infinitely large number. So, in case where round off error is important, we will see that Gram Schmidt modified Gram Schmidt gives much better result than Gram Schmidt. And actually, Gram Schmidt algorithm fails you fails to provide you an orthogonal set of vectors. So, in next class, we will see an example with modified Gram Schmidt and Gram Schmidt algorithm and then we will see a q , what is called a q th decomposition or how a matrix can be decomposed into q matrix and some

other matrix which is an R matrix and that can be used for matrix solution of matrix equations.

Thank you.
