Lecture – 18
Lower Bounds for Variance – IV

We have discussed the concept of minimum variance; that means, among unbiased estimators the estimator which has the minimum variance is some considered to be the best. In general, we can always compare two unbiased estimators by comparing their variances. That means, the one which has the smaller variance will be considered to be more stable or better. So, there is a classical concept of efficiency of estimators based on this. Let me discuss that here efficiency of estimators.

(Refer Slide Time: 00:47)

So, let T_1 and T_2 be two unbiased estimators of a parameter say $g(\theta)$. And let us assume that they have the finite second moment, this condition is required because the variance must exist. So, we define the efficiency of T_2 relative to T_1 by so, we use a notation $eff(T_2/T_1)$ it is equal to variance of T_2 divided by variance of T_1 .

Naturally, if the variances are equal then the efficiency will be equal to 1. If the efficiency is less than 1; that means, variance of T_2 is less than variance of T_1 ; that means, T_2 is more efficient than T_1 . Conversely if the efficiency is more than 1 then variance of T_2 will become bigger than variance of T_1 ; that means, T_1 is better than T_2 .

2. So, we say that T_2 is more efficient than T_1 if efficiency function is less than 1. Now, this is regarding any two estimators. Now, in general give an any unbiased estimator we can consider its efficiency with respect to the Rao Cramer lower bound.

So, for example, we may consider an estimator which attains the FRC lower bound if that is so, then that is a benchmark or you can say the best thing. So, anything which is bigger than that its efficiency will be considered with respect to that; that means, its efficiency will be bigger than 1. So, we can also define the efficiency of an unbiased estimator with respect to the FRC lower bound that is, we may say let me give another notation we will call it E notation.

So, efficiency of an unbiased estimator E_f efficiency of an estimator T we define as variance of T divided by FRC lower bound for the variance of an unbiased estimator for that parameter. Suddenly, we know that sometimes this may be attained sometimes this may not be attained. So, these definitions are not full-proof another thing is that in certain cases we may not consider unbiased estimators. Because, if we consider only mean squared error as a criteria it may turn out that the mean squared error is less than the variance by combining certain terms.

We can also consider that although this may not be attained, but asymptotically it may be attained. So, we can give a definition that if limit of this is equal to 1, then we say that T is asymptotically efficient. So, here if 1 is attained, T is the most efficient. Let us look at some examples here.

(Refer Slide Time: 05:25)

Examples. 1, $X \sim \mathcal{P}(\lambda)$, our parameter of interest is
 $p(X=0) = e^{-\lambda} = g(\lambda)$
 FRLB for $e^{-\lambda} = \{g'(\lambda)\}^2 \cdot \{FRLB \text{ for } \lambda\}$
 $= \lambda e^{-2\lambda}$
 Consider an estimator $\beta(X) = \begin{cases} 1 & \text{if } X=0 \\ 0 & \text{if } X=1, 2, \dots \end{cases}$
 $E\beta(X) = p(X=0) + 0 \sum_{i=1}^{\infty} p(X=i) = e^{-\lambda}$
 So $\beta(X)$ is unbiased for $e^{-\lambda}$.
 $E\beta^2(X) = e^{-\lambda}$, $\text{Var}(\beta(X)) = e^{-\lambda} - e^{-2\lambda}$.
 $e^{-\lambda} - e^{-2\lambda} > \lambda e^{-2\lambda} \Leftrightarrow e^{\lambda} > 1 + \lambda, \lambda > 0$
 which is always true.

Let us go back to the Poisson example and for convenience let me restrict attention to 1 observation suppose, X follows Poisson λ . And here, our parameter of interest is say probability X is equal to 0 that is $e^{-\lambda}$. Of course, we may ask the question that why we are considering this function.

Now, usually a Poisson distribution is the distribution of the number of arrivals, number of occurrences, during a given time interval or during a given area or during a given space etcetera. Now, what happens for example, if you are considering a q service q then how many people are arriving that will denote the number X . Then certainly it is of interest to know that if X is equal to 0; that means, there is a slack period. Because, if in a service q it may happen that we have to imply service personnel; that means, the person who will be giving the service.

For example, it is a railway ticket counter, it is a ticket counter at a cinema hall or it is a it is a service counter at a popular say cafe. So, therefore, persons are required there are person all are required. In the when there are no person; that means, when X is equal to 0 we need not deploy the people or we may deploy less number of people. So, certainly in such cases it is of interest to know or estimate the probability of 0 occurrence.

So, this gives us this parametric function $e^{-\lambda}$ to the power minus λ suddenly it is a non-linear function of λ therefore, the variance of an unbiased estimator of $e^{-\lambda}$ to the power minus λ can never attain the lower bound. Let us look at this what will be

the lower bound? FRC lower bound for e to the power minus λ that is equal to g prime λ square into the FRC for λ . For λ it is λ by n and if n is equal to 1 this is simply λ .

The derivative of g λ is e to the power minus λ with a minus sign when we squared it we get e to the power minus 2 λ . So, this is λ this is a lower bound. Now, let us consider an estimator say β X is equal to 1 if X is equal to 0 it is equal to 0 if X is equal to 1 2 and so on. Then, if you look at expectation of β X that is equal to 1 into probability X equal to 0 plus 0 into probability is equal to X is equal to say i i is equal to 1 to infinity. So, this becomes 0. So, this is e to the power minus λ .

So, β X is unbiased for e to the power minus λ . However, if you look at expectation β square, now this will again be same and therefore, variance of β that is also e to the power minus λ minus e to the power minus 2 λ . Now, if you compare this with the lower bound e to the power minus λ minus e to the power minus 2 λ greater than λ e to the power minus 2 λ . Because, this is equivalent to e to the power λ greater than 1 plus λ for λ positive which is always true. So, you can see that this lower bound is not attained.

(Refer Slide Time: 09:57)

We can actually show that β is the only unbiased estimator. (12)

Let $\alpha(X)$ be an unbiased estimator of $e^{-\lambda}$.

$$\Rightarrow E \alpha(X) = e^{-\lambda}$$

$$\Rightarrow \sum_{x=0}^{\infty} \alpha(x) \frac{e^{-\lambda} \lambda^x}{x!} = e^{-\lambda} \quad \forall \lambda > 0$$

$$\Rightarrow \alpha(0) + \alpha(1) \lambda + \alpha(2) \frac{\lambda^2}{2!} + \dots = 1 \quad \forall \lambda > 0$$

$$\Leftrightarrow \alpha(0) = 1, \alpha(1) = \alpha(2) = \dots = 0$$

$$\Rightarrow \alpha(x) = \beta(x) \quad \forall x.$$

So $\beta(X)$ is UMVUE.

However, we can use another argument to actually prove that β X is we can actually show that β is the only unbiased estimator. We can proceed by the basic principles let

us consider say alpha X let alpha X be an unbiased estimator of e to the power minus lambda. Then we should have expectation of alpha X equal to e to the power minus lambda.

Now, let us write down this relation alpha x e to the power minus lambda lambda to the power x by x factorial is equal to e to the power minus lambda for all lambda. Now, this e to the power minus lambda you can remove from both the sides because this is a positive term. So, this is reducing to then alpha 0 plus alpha 1 into lambda plus alpha 2 into lambda square by 2 factorial and so on is equal to 1. So, left hand side is a power series in lambda and right hand side is simply a constant.

So, this is true if and only if the coefficients match; that means, alpha zero must be 1 and alpha 1 alpha 2 and so on all of them must be 0 which is the same as the function beta because beta 1 beta 0 was 1 and beta 1 beta 2 and so on all of them were 0. So, this alpha function and beta functions are the same. So, beta must be UMVUE. So, although here the lower bound is not attained, but actually beta will be the most efficient estimator here. Let me give an example of comparing two unbiased estimators with respect to their variances.

(Refer Slide Time: 12:11)

Example: let X_1, \dots, X_n be i.i.d. r.v. with mean μ and variance $\sigma^2 (< \infty)$.

$$T_1 = \bar{X}, \quad T_2 = \frac{2}{n(n+1)} \sum_{i=1}^n i X_i$$

$E(T_1) = \mu, \quad \text{Var}(T_1) = \frac{\sigma^2}{n}$. So T_1 is unbiased & consistent for μ .

$$E(T_2) = \frac{2}{n(n+1)} \sum_{i=1}^n i \mu = \frac{2}{n(n+1)} \cdot \frac{n(n+1)}{2} \cdot \mu = \mu.$$

$$\text{Var}(T_2) = \frac{4}{n^2(n+1)^2} \sum_{i=1}^n i^2 \sigma^2 = \frac{4}{n^2(n+1)^2} \cdot \frac{n(n+1)(2n+1)}{6} \sigma^2$$

$$= \frac{2}{3} \cdot \frac{2n+1}{n(n+1)} \sigma^2 \rightarrow 0 \text{ as } n \rightarrow \infty.$$

So T_2 is also unbiased and consistent for σ^2 .

The estimators may both may be unbiased, both may be consistent etcetera. So, let us take another example. I am not taking any distributional form let us consider say $X_1 X_2$

X_n be independent and identically distributed random variables with say mean μ and variance σ^2 ; obviously, we are assuming that variance is finite here.

Now, you consider 2 unbiased estimators here let me take say T_1 is equal to \bar{X} and T_2 is equal to $\frac{2}{n+1} \sum_{i=1}^n X_i$. Now obviously, if you look at expectation of T_1 this we have seen that sample mean is unbiased for the population mean, the variance of this is equal to $\frac{\sigma^2}{n}$. So, if estimator is unbiased and its variance converges to 0 then we also know that it will be consistent. So, what we are seeing that T_1 is unbiased and consistent for estimating μ .

Now, if you look at T_2 . So, that is equal to expectation of T_2 is equal to $\frac{2}{n+1} \sum_{i=1}^n E[X_i]$ that is again μ . So, $\frac{2}{n+1} \sum_{i=1}^n \mu$. So, you get $\frac{2}{n+1} \cdot n \cdot \mu$. So, these terms cancel out you get only μ . So, T_2 is also unbiased let us look at variance of T_2 .

Now, variance of T_2 if you take this is constant. So, it will become $\frac{4}{(n+1)^2} \sum_{i=1}^n \text{variance of } X_i$, variance of X_i is σ^2 . Since, we have assumed independence of the observations the correlation or covariance term will not come here you get this. Now, σ^2 we have the formula so you get $\frac{4}{(n+1)^2} \cdot n \cdot \sigma^2$. So, after simplification you get it as $\frac{4n}{(n+1)^2} \sigma^2$.

So, as n tends to infinity this goes to 0. So, T_2 is also unbiased and consistent for σ^2 . However, let us compare the variances what is variance of T_2 by variance of T_1 .

(Refer Slide Time: 15:41)

$$T_1 = \bar{X}, \quad T_2 = \frac{1}{n(n+1)} \sum_{i=1}^n i X_i$$
$$E(T_1) = \mu, \quad \text{Var}(T_1) = \frac{\sigma^2}{n}. \quad \text{So } T_1 \text{ is unbiased \& consistent for } \mu.$$
$$E(T_2) = \frac{1}{n(n+1)} \sum_{i=1}^n i \mu = \frac{1}{n(n+1)} \cdot \frac{n(n+1)}{2} \cdot \mu = \mu.$$
$$\text{Var}(T_2) = \frac{1}{n^2(n+1)^2} \sum_{i=1}^n i^2 \sigma^2 = \frac{1}{n^2(n+1)^2} \cdot \frac{n(n+1)(2n+1)}{6} \sigma^2$$
$$= \frac{1}{3} \cdot \frac{2n+1}{n(n+1)} \sigma^2 \rightarrow 0 \text{ as } n \rightarrow \infty.$$

So T_2 is also unbiased and consistent for μ . $\frac{\text{Var}(T_2)}{\text{Var}(T_1)} = \frac{2}{3} \frac{(2n+1)}{(n+1)} > 1$ for $n > 1$.

In general T_1 is more efficient than T_2 .

Variance of T_2 divided by variance of T_1 . So, sigma square is coming here sigma square is appearing here by n by n so that will cancel out. So, you get the term as 2 by 3 $2n$ plus 1 divided by n plus 1 .

Obviously, this is always greater than 1 for n greater than 1 . If n is equal to 1 of course, this will be equal to 1 and if n is equal to 1 actually T_1 and T_2 are both equal to X_1 so that case is of not any interest. So, in general T_1 is more efficient than T_2 . So, here you have seen we have 2 estimators both of which are unbiased as well as consistent for the sample mean, but one of them can be preferred over the other if we are applying the criteria of a smaller variance.

(Refer Slide Time: 16:59)

Example: Let $X_1, \dots, X_n \sim N(0, \sigma^2)$
 Consider the estimation of σ .
 $f(x, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2}$, $x \in \mathbb{R}$, $\sigma > 0$.
 $\log f(x, \sigma) = -\log \sigma - \frac{1}{2} \log 2\pi - \frac{x^2}{2\sigma^2}$
 $\frac{\partial \log f}{\partial \sigma} = -\frac{1}{\sigma} + \frac{x^2}{\sigma^3} = \frac{1}{\sigma^3} \left(\frac{x^2}{\sigma^2} - 1 \right)$
 $E \left(\frac{\partial \log f}{\partial \sigma} \right)^2 = \frac{1}{\sigma^2} E \left(\frac{x^2}{\sigma^2} - 1 \right)^2 = \frac{2}{\sigma^2}$
 $I_{\Sigma}(\sigma) = \frac{2n}{\sigma^2}$, FRCLB for $\sigma = \frac{\sigma^2}{2n}$.

Now, let me also take another distribution say suppose we consider a random sample from a normal distribution, where mean I was assume to be 0 and variance is sigma square. We have already discussed this example in the context of estimation of sigma square when mu are some fixed value mu naught. Now, whenever mu is some fixed value mu naught you can always shift the observations so that the mean can be made to be 0.

Now, suppose my interest is not to consider estimation of sigma square, but the estimation of sigma. So, consider the estimation of sigma say. Now let us look at the lower bound the density function is of the form $\frac{1}{\sigma\sqrt{2\pi}} e^{-x^2/2\sigma^2}$, where x is of course, any real value. Log is equal to minus log sigma minus $\frac{1}{2} \log 2\pi$ minus $\frac{x^2}{2\sigma^2}$; so, derivative of this with respect to sigma that is $-\frac{1}{\sigma} + \frac{x^2}{\sigma^3}$. Now derivative of this will become 0 then derivative of $\frac{1}{\sigma^2}$ is $-\frac{2}{\sigma^3}$. So, it will become $\frac{x^2}{\sigma^3} - \frac{2}{\sigma^3}$ that is equal to $\frac{1}{\sigma^3} (x^2 - 2)$ we can write it as $\frac{1}{\sigma^3} (x^2 - 2)$.

So, expectation of $\frac{\partial \log f}{\partial \sigma}$ is equal to $\frac{1}{\sigma^3} E(x^2 - 2)$. Now, if X follows normal 0 sigma square then $\frac{X}{\sigma}$ follows normal 0 1 $\frac{X^2}{\sigma^2}$ will follow chi square on

1 degree of freedom. So, therefore, this will have expectation 1 and therefore, expectation of the variable minus its mean square that is going to be the variance.

Now, variance of a chi square is twice its degrees of freedom. So, this term will become equal to 2 so, this is simply equal to 2 by sigma square. Say if we consider the information that will be equal to $2n$ by sigma square. So, the FRC lower bound for estimation of sigma that will be equal to sigma square by $2n$. In the following class I will consider two estimators for this see whether they any of them attain the lower bound and also compare them so, that I will be doing in the following lecture.
