**Lower Bounds for Variance – VII**

In the previous lecture we have discussed the lower bound for the variance of an unbiased estimator when certain regularity conditions are satisfied. The first one assumed first order derivatives. And therefore, we had the Frechet Rao Cremer lower bound and when we assume higher order derivatives existing then we had Bhattacharya's lower bound for the variance. We have seen that Bhattacharya's lower bound is a sharper lower bound.

However, it is not very frequently used because the calculations involved to calculate the Bhattacharya's lower bound are quite involved and higher order moments are frequently used. And therefore, it becomes difficult to use that. Now there are certain densities for example, uniform distribution, exponential distribution with a location parameter Pareto distribution etcetera where the regulatory conditions are not satisfied.

In fact, you can notice that many of these densities are the ones where the range of the variable and the parameter is mixed up for example, in the uniform distribution  $x$  lies between 0 to  $\theta$ . If you consider say exponential distribution then  $x$  is greater than  $\theta$ .

(Refer Slide Time: 01:43)

Now, in these cases I mentioned yesterday that we have another inequality that is called Chapman Robbins Kiefer inequality and let me repeat the statement once again.

So, as usual we have a probability density or probability mass function denoted by  $f_X$  theta, where theta belongs to omega. Now, consider any unbiased estimator of the parametric function  $g$  theta, we defined the ratio of the densities  $f_X$  phi by  $f_X$  theta at two parameter points phi and theta. Now this ratio should be well defined. That means the set of values where the numerator is positive and the set of values where the numerator is positive.

So, the numerator should be positive more often. So, we have this that the set of  $x$  such that  $f_X$  phi is greater than 0 is a subset of the set of values  $x$  for which  $f_X$  theta is positive. Now for this ratio we consider the variance when the two density is  $f_X$  theta and we denoted by  $A$  phi theta. Then the Chapman Robbins Kiefer inequality says that variance of unbiased estimator  $T$  will be greater than or equal to supremum value of  $g$  phi minus  $g$  theta a square divided by  $A$  phi theta where the supremum o is taken over phi for which this condition is satisfied.

Let us look at the proof of this now.

(Refer Slide Time: 03:12)

Lecture - 11

Proof of the CRK Inequality

$$\begin{aligned}
 g(\phi) - g(\theta) &= E_{\phi} T(X) - E_{\theta} T(X) = \int T(z) (f(z, \phi) - f(z, \theta)) d\mu(z) \\
 &= \int T(z) \left\{ \frac{f(z, \phi) - f(z, \theta)}{f(z, \theta)} \right\} f(z, \theta) d\mu(z) \\
 &= E_{\theta} \left[ T(X) \left\{ \frac{f(X, \phi)}{f(X, \theta)} - 1 \right\} \right] \quad E_{\theta} \frac{f(X, \phi)}{f(X, \theta)} = \int \frac{f(z, \phi) f(z, \theta)}{f(z, \theta) f(z, \theta)} d\mu(z) \\
 &= \text{Cov}_{\theta} \left( T, \frac{f(X, \phi)}{f(X, \theta)} \right) \quad = 1 \\
 \Rightarrow (g(\phi) - g(\theta))^2 &= \text{Cov}_{\theta}^2 \left( T, \frac{f(X, \phi)}{f(X, \theta)} \right) \leq \text{Var}_{\theta}(T) \text{Var}_{\theta} \frac{f(X, \phi)}{f(X, \theta)} \\
 &= \text{Var}_{\theta}(T) A(\phi, \theta) \\
 \Rightarrow \text{Var}_{\theta}(T) &\geq \frac{(g(\phi) - g(\theta))^2}{A(\phi, \theta)}
 \end{aligned}$$

Let us write  $g(\phi) - g(\theta)$ . Now this is equal to expectation of  $T(X)$  at  $\phi$  minus expectation of  $T(X)$  at  $\theta$ . So, that is equal to; now we are assuming the density function or the mass function as  $f(X, \theta)$ . So, if I make use of the generalized Lebesgue integral then this can be written as  $T(X) f(X, \phi)$ . So, let me use multi observations that is  $x_1 \times x_2 \times \dots \times x_n$ .

So, we are denoting it by  $x - f(X, \theta) d\mu(x)$ . Now this one we write as integral  $T(X) f(X, \phi) - f(X, \theta)$  divided by  $f(X, \theta)$  into  $f(X, \theta)$ . So, if you look at this expression here we have the density and then there is a function here. So, this can be considered as expectation of  $T(X) \frac{f(X, \phi)}{f(X, \theta)}$  minus 1. Now this is the expectation when the true density is  $\theta$ , because here the density function that has been taken is  $f(X, \theta)$ .

So this, we can write as, now again observe something for example, expectation of  $f(X, \phi)$  by  $f(X, \theta)$ , what it is? With respect to  $\theta$ , that is equal to integral  $f(X, \phi)$  by  $f(X, \theta)$  into  $f(X, \theta) d\mu(x)$ , now this cancels out. So, this becomes integral of the density, this is equal to 1; that means, expectation of this term is equal to 0. Now if I have expectation of product of two expressions and expectation of one of them is 0 then this is nothing, but the covariance between  $T$  and  $f(X, \phi)$  by  $f(X, \theta)$ .

Therefore we can say that  $(g(\phi) - g(\theta))^2$  a square that is equal to covariance a square of  $T$  and  $f(X, \phi)$  by  $f(X, \theta)$  at this point I apply the Cauchy Schwarz inequality.

So, covariance square is less than or equal to variance of T into variance of f X phi by f X theta, remember the notation here, variance of f X phi by f X theta had denoted by A phi theta. So, this is equal to variance of theta into A phi theta. So, what we are getting? g phi minus g theta a square is less than or equal to variance T into A phi theta.

So, we can write variance of T is greater than or equal to g phi minus g theta a square divided by A phi theta.

(Refer Slide Time: 06:59)

$$\begin{aligned}
 g(\phi) - g(\theta) &= E_{\phi} T(X) - E_{\theta} T(X) = \int T(z) (f(z, \phi) - f(z, \theta)) \mu(z) \\
 &= \int T(z) \left\{ \frac{f(z, \phi) - f(z, \theta)}{f(z, \theta)} \right\} f(z, \theta) \mu(z) \\
 &= E_{\theta} \left[ T(X) \left\{ \frac{f(X, \phi)}{f(X, \theta)} - 1 \right\} \right] \quad E_{\theta} \frac{f(X, \phi)}{f(X, \theta)} = \int \frac{f(z, \phi) f(z, \theta)}{f(z, \theta) f(z, \theta)} \mu(z) \\
 &= \text{Cov}_{\theta} \left( T, \frac{f(X, \phi)}{f(X, \theta)} \right) \quad = 1 \\
 \Rightarrow (g(\phi) - g(\theta))^2 &= \text{Cov}_{\theta}^2 \left( T, \frac{f(X, \phi)}{f(X, \theta)} \right) \leq \text{Var}_{\theta}(T) \text{Var}_{\theta} \frac{f(X, \phi)}{f(X, \theta)} \\
 &= \text{Var}_{\theta}(T) A(\phi, \theta) \\
 \Rightarrow \text{Var}_{\theta}(T) &\geq \frac{(g(\phi) - g(\theta))^2}{A(\phi, \theta)}
 \end{aligned}$$

Now, the left hand side is free from phi the left hand side is dependent only on theta and the right hand side is dependent upon phi and theta both. So, on the right hand side if I take expectation, the maximum over all phi then also this inequality will be true.

Now, when I say supremum over all phi or maximum over all phi then what are the phi's? The phis are the ones which satisfy this condition a star.

(Refer Slide Time: 07:33)

Taking the supremum on the right hand side with respect to  $\phi$  subject to condition (\*), we get

$$\text{Var}_\theta(T) = \sup_{\phi \in \Omega} \frac{\{g(\phi) - g(\theta)\}^2}{A(\phi, \theta)}$$

Example 1.  $X \sim U(0, \theta)$ ,  $\theta > 0$ . Consider unbiased estimator  $T = \theta$ .

$$f(x, \theta) = \begin{cases} \frac{1}{\theta}, & 0 < x < \theta \\ 0, & \text{ew} \end{cases}$$

$$f(x, \phi) = \begin{cases} \frac{1}{\phi}, & 0 < x < \phi \\ 0, & \text{ew} \end{cases}$$

$$\frac{f(x, \phi)}{f(x, \theta)} = \begin{cases} \frac{\theta}{\phi}, & x < \phi < \theta \\ 0, & \phi < x < \theta \\ \frac{\theta}{\phi}, & \frac{1}{\phi} \cdot \theta = 1 \end{cases}$$

$$E_\theta \frac{f(x, \phi)}{f(x, \theta)} = \begin{cases} \frac{\theta}{\phi}, & \frac{1}{\phi} \cdot \theta = 1 \\ 0 \end{cases}$$

So, we have then this that taking the supremum on the right hand side with respect to  $\phi$ , subject to condition a star we get variance of  $T$  greater than or equal to supremum of  $\phi$ . And let me write here  $\phi$  satisfy a belonging to  $\Omega$   $g(\phi) - g(\theta)$  whole square by  $A(\phi, \theta)$ . So, we have proved the Chapman Robbins Kiefer inequality which we call in abbreviated form as CRK inequality. Let me give example of application of CRK inequality when the regularity conditions are not satisfied. So, let us take say  $x$  following uniform distribution on the interval 0 to  $\theta$ . So, we consider say unbiased estimation of  $\theta$ .

Now, here we know that the density function is of the form  $1/\theta$   $0 < x < \theta$  and it is equal to 0 elsewhere. If I write at another parameter point say  $f(x, \phi)$  then it is equal to  $1/\phi$   $0 < x < \phi$  and 0 elsewhere. So, if we consider the ratio  $f(x, \phi)/f(x, \theta)$  then that will be equal to  $\theta/\phi$   $0 < x < \phi$  and  $0$  elsewhere in this region.

That means it will become  $\theta/\phi$  when we are having  $\phi < \theta$  and  $x$  is less than  $\phi$  and if  $\phi$  is less than  $x < \theta$  then this will become 0. Now the case when both are 0 we are not considering that thing in. In fact, we can consider the ratio to be 0 by default or by convention in that case, because there this ratio will not be defined there.

So, now once we have the expression for this we can calculate the expectation and the variance of this term. So, for example, expectation of  $f(x, \phi)$  by  $f(x, \theta)$  when  $\theta$  is the distribution so you are getting it as equal to  $\theta$  by  $\phi$  integral. Now you have to consider the range of  $x$  from 0 to  $\phi$  here and the density is  $1$  by  $\theta$ , because although the density is  $1$  by  $\theta$ , but the range of  $x$  cannot be 0 to  $\theta$ , because  $\phi$  is less than  $\theta$  here and  $x$  is less than  $\phi$ . So, the range is only this. So, here  $\theta$  cancels out and you get this value simply as 1.

(Refer Slide Time: 11:14)

Handwritten mathematical derivation on a whiteboard:

$$\text{Var}_\theta(T) = \frac{\int_{\phi}^{\theta} A(\phi, \theta)}{\int_{\phi}^{\theta} f(x, \theta)}$$

Example 1  $X \sim U(0, \theta), \theta > 0$ . Consider unbiased estimator  $\hat{\theta}$ .

$$f(x, \theta) = \begin{cases} \frac{1}{\theta}, & 0 < x < \theta \\ 0, & \text{ew} \end{cases}$$

$$f(x, \phi) = \begin{cases} \frac{1}{\phi}, & 0 < x < \phi \\ 0, & \text{ew} \end{cases}$$

$$\frac{f(x, \phi)}{f(x, \theta)} = \begin{cases} \frac{\theta}{\phi}, & x < \phi < \theta \\ 0, & \phi < x < \theta \end{cases}$$

$$E_\theta \left[ \frac{f(x, \phi)}{f(x, \theta)} \right] = \int_0^\phi \frac{\theta}{\phi} \cdot \frac{1}{\theta} dx = 1$$

$$E_\theta \left[ \left( \frac{f(x, \phi)}{f(x, \theta)} \right)^2 \right] = \int_0^\phi \frac{\theta^2}{\phi^2} \cdot \frac{1}{\theta} dx = \frac{\theta}{\phi}$$

$$A(\phi, \theta) = \text{Var}_\theta \left( \frac{f(x, \phi)}{f(x, \theta)} \right) = \frac{\theta}{\phi} - 1$$

Similarly, if I consider expectation of  $f(x, \phi)$  by  $f(x, \theta)$  whole square then this will become 0 to  $\phi$   $\theta$  a square by  $\phi$  square  $1$  by  $\theta$   $d\theta$ . So, this is simply  $\theta$  by  $\phi$ ; that means, a  $\theta$  by  $\phi$  that is the variance of  $f(x, \phi)$  by  $f(x, \theta)$  that will be equal to  $\theta$  by  $\phi$  minus 1, this is the variance when the true distribution has been assumed to be  $\theta$ .

Let us revisit the calculations, we are writing down the distribution at two parameter points  $\theta$  and  $\phi$  and then I write down the ratio  $f(x, \phi)$  by  $f(x, \theta)$ . Now notice here there is one case when both of them are positive, if both of them are positive then the ratio will be  $\theta$  by  $\phi$ .

Now, that is going to be true when  $x$  is less than  $\phi$  less than  $\theta$  and of course, it will also be true for  $x$  less than  $\theta$  less than  $\phi$ , but in that case then we have to also take up that the density in the denominator may become 0. So, we will not take that case, it is

equal to 0 when  $x$  is between  $\phi$  and  $\theta$ . Therefore, when you consider the expectation it is  $\theta$  by  $\phi$  over this region only that is 0 to  $\phi$  and when we integrate we get 1.

In a likewise manner the expectation of  $f(X|\phi)$  by  $f(X|\theta)$  is square can be calculated and we get the term as  $\theta^2$  by  $\phi^2$  1 by  $\theta$  integral of this quantity from 0 to  $\phi$ , with respect to  $x$ . So, this is not with respect to  $\theta$  it is with respect to  $x$  here. So, this value turns out to be simply  $\theta$  by  $\phi$ , and therefore the variance is expectation of a square minus expectation whole square that is  $\theta$  by  $\phi$  minus 1. Now let us consider the CRK inequality.

(Refer Slide Time: 13:49)

$g(\theta) = \theta$   

$$\frac{\{g(\phi) - g(\theta)\}^2}{A(\phi, \theta)} = \frac{\phi(\phi - \theta)^2}{(\theta - \phi)} = \phi(\theta - \phi)$$
 We find  $\sup_{\phi < \theta} \phi(\theta - \phi) = \frac{\theta}{2}(\theta - \frac{\theta}{2}) = \frac{\theta^2}{4}$  attained at  $\phi = \frac{\theta}{2}$ .  
 CRKLB is  $\frac{\theta^2}{4}$ .  
 $T = 2X$ ,  $E(T) = \theta$ ,  $\text{Var}(2X) = 4 \cdot \text{Var}(X) = 4 \cdot \frac{\theta^2}{3} = \frac{4\theta^2}{3} > \frac{\theta^2}{4}$ .  
 2. Let  $X \sim f(x, \theta) = \begin{cases} e^{\theta-x}, & x > \theta \\ 0, & x \leq \theta \end{cases}$   
 We want CRKLB for unbiased estimators of  $\theta$ .  
 $f(x, \phi) = \begin{cases} e^{\phi-x}, & x > \phi \\ 0, & x \leq \phi. \end{cases}$

So, for CRK inequality we need  $g(\theta)g(\phi)$ . So, here  $g(\theta)$  is  $\theta$  itself. So, if we consider the term  $g(\phi) - g(\theta)$  whole square divided by  $A(\phi, \theta)$ , then that is equal to  $\phi(\theta - \phi)$ . Now in this  $\theta - \phi$  term will cancel out. So, you get  $\phi$  into  $\theta - \phi$ . Now in order to find out the supremum with respect to  $\phi$  such that the condition is satisfied, we should have  $\phi$  less than or equal to  $\theta$ . So, we find supremum of this quantity such that  $\phi$  is less than  $\theta$ .

So, now this is a simple function here, if you differentiate we will get  $\theta - 2\phi$ , and that if you put equal to 0 you will get  $\phi$  is equal to  $\theta/2$ . So, that is equal to  $\theta/2$  into  $\theta - \theta/2$  that is equal to  $\theta^2/4$  this is attained at

$\phi$  is equal to  $\theta$  by 2. Therefore, CRK lower bound is  $\theta^2$  by 4. So, we have seen here that even if the FRCLB is not available that is Frechet Rao Cramer Lower Bound is not available we can find out lower bound for the variance of an unbiased estimator.

In the case of uniform distribution for example, we know for example,  $2X$  we can consider then expectation of  $2X$  is equal to  $\theta$ . So, this is an unbiased estimator what is variance of  $2X$ , variance of  $2X$  is equal to 4 times variance of  $x$  that is equal to 4 times  $\theta^2$  by 12 that is  $\theta^2$  by 3. Of course, you can see that this is greater than  $\theta^2$  by 4, we can actually show later on that  $2X$  is minimum variance unbiased estimator in this problem. We can show it directly also and we will later on use a concept of sufficiency and completeness from there also we will show this thing.

Let us consider another example of non regular distribution, say exponential distribution with a location parameter  $\phi$  to the power  $\theta - x$  where  $x$  is greater than  $\theta$  it is 0, for  $x$  less than or equal to  $\theta$ . So, here we want the CRK lower bound for unbiased estimator of  $\theta$ . So, let us consider  $f(x, \phi)$  here,  $f(x, \phi)$  will become  $e^{\phi - x}$  for  $x$  greater than  $\phi$  and 0 for  $x$  less than or equal to  $\phi$

(Refer Slide Time: 17:36)

$$\frac{f(x, \phi)}{f(x, \theta)} = \begin{cases} e^{\phi - \theta} & x > \phi > \theta \\ 0 & \phi > x > \theta \end{cases}$$

$$E_{\theta} \left\{ \frac{f(x, \phi)}{f(x, \theta)} \right\} = \int_{\phi}^{\infty} e^{\phi - \theta} \cdot e^{\theta - x} dx = 1$$

$$E_{\theta} \left\{ \left( \frac{f(x, \phi)}{f(x, \theta)} \right)^2 \right\} = \int_{\phi}^{\infty} e^{2\phi - 2\theta} \cdot e^{\theta - x} dx = e^{\phi - \theta}$$

$$A(\phi, \theta) = \text{Var}_{\theta} \left( \frac{f(x, \phi)}{f(x, \theta)} \right) = e^{\phi - \theta} - 1.$$

CRK Lower bound for the variance of unbiased estimator of  $\theta$  is

$$\sup_{\phi > \theta} \frac{(\phi - \theta)^2}{e^{\phi - \theta} - 1}$$

So, once again we consider the ratio  $f(x, \phi)$  by  $f(x, \theta)$ ; consider the ratio  $f(x, \phi)$  by  $f(x, \theta)$  that will be equal to.

Now,  $e$  to the power  $\phi$  minus  $x$  divided by  $e$  to the power  $\theta$  minus  $x$ ; so  $e$  to the power minus  $x$  will cancel out. And we are left with the term  $e$  to the power  $\phi$  minus  $\theta$  for  $x$  greater than  $\phi$  greater than  $\theta$ . And it is equal to 0 for  $\phi$  less than  $x$  greater than  $x$  greater than  $\theta$ , we are not considering the case  $\phi$  less than  $\theta$  here because in that case there will be a place where you will have 0 in the denominator. So, we are not considering that case here.

So, expectation of  $f(x, \phi)$  divided by  $f(x, \theta)$  when  $\theta$  is the true parameter value it is equal to  $e$  to the power  $\phi$  minus  $\theta$   $e$  to the power  $\theta$  minus  $x$   $d x$  from  $\phi$  to infinity. That is equal to, now if you look at this  $\theta$  cancels out you get density  $e$  to the power  $\phi$  minus  $x$  from  $\phi$  to infinity. So, the value of integral will be equal to 1; similarly, if we consider the expectation of  $f(x, \phi)$  by  $f(x, \theta)$  a square that is equal to integral  $\phi$  to infinity  $e$  to the power twice  $\phi$  minus twice  $\theta$ .

$E$  to the power  $\theta$  minus  $x$   $d x$  that is equal to  $e$  the power  $\phi$  minus  $\theta$  so  $A(\phi, \theta)$  that is variance of  $f(X, \phi)$  by  $f(X, \theta)$  that is equal to  $e$  to the power  $\phi$  minus  $\theta$  minus 1. Therefore, the Chapman Robbins Kiefer lower bound for the variance of unbiased estimator of  $\theta$  is supremum of  $\phi$  minus  $\theta$  square divided by  $e$  to the power  $\phi$  minus  $\theta$  minus 1, where  $\phi$  is greater than  $\theta$ .

(Refer Slide Time: 20:15)

$$E_{\theta} \left\{ \frac{f(x, \phi)}{f(x, \theta)} \right\}^2 = \int_{\phi}^{\infty} e^{2\phi - 2\theta} \cdot e^{\theta - x} dx = e^{\phi - \theta}$$

$$A(\phi, \theta) = \text{Var}_{\theta} \left( \frac{f(x, \phi)}{f(x, \theta)} \right) = e^{\phi - \theta} - 1$$

C.R.K. Lower bound for the variance of unbiased estimator of  $\theta$  is

$$\sup_{\phi > \theta} \frac{(\phi - \theta)^2}{e^{\phi - \theta} - 1} = \sup_{t > 0} \frac{t^2}{e^t - 1} > 0, \quad t = \phi - \theta$$

Now, if  $\phi$  is greater than  $\theta$  basically it means we can consider it as a problem supremum say  $t$  greater than 0,  $t$  square by  $e$  to the power  $t$  minus 1, because  $\phi$  minus

theta is positive. So, I can replace it by t, now you can notice that this is a positive function we can also notice here that.

(Refer Slide Time: 20:56)

$\lim_{t \rightarrow 0} h(t) = \lim_{t \rightarrow 0} \frac{2t}{e^t} = \frac{0}{1} = 0$   
 $\lim_{t \rightarrow \infty} h(t) = \lim_{t \rightarrow \infty} \frac{2t}{e^t} = \lim_{t \rightarrow \infty} \frac{2}{e^t} = 0$   
 $h'(t) = \frac{t \{ (2-t)e^t - 2 \}}{(e^t - 1)^2} < 0 \text{ for } t \geq 2$   
 $> 0 \text{ for } t \leq 1$   
 $h'(t)$  changes sign between 1 & 2. We numerically solve  
 $(2-t)e^t = 2$ , to get  $t = 1.59362$   
 At this point  $h(t) = 0.6476$   
 CRRLB is 0.6476.  
 In this case an unbiased estimator for  $\theta$  is  $T = X-1$ .  
 $\text{Var}(T) = \text{Var}(X) = 1 > 0.6476$

Let me call this as say h t, then you can notice here that limit of h t as t tends to 0 that is, now if you look at this term here this is 0 by 0 form as t tends to 0.

So, we can apply L Hospital's rule. So, you will get limit 2 T by e to the power t s t tends to 0 which is again 0 by 0 form. So, we can further take 2 by e to the power, now this is not 0 by 0 form this is actually 0. Similarly if I consider limit of h t s t tends to infinity that is equal to limit as t tends to infinity to t by e to the power t. That is equal to limit as t tends to infinity of 2 by e to the power t that is equal to 0.

So, as t tends to 0 or t tends to infinity, the function h t tends to this function ht tends to 0. Now let us consider the derivative g prime t that is equal to t times 2 minus t e to the power t minus 2 divided by e to the power t minus 1 square. This is less than 0 for t greater than or equal to 2 and it is greater than 0 for t less than or equal to 1. Actually we can show that g prime t has a change of sign between 1 and 2.

So, you can numerically solve this equal to 0. So, we numerically solve this 2 minus t e to the power t is equal to 2 to get t as approximately 1.59362, at this point h t function sorry this is I was writing h. So, this is will be h prime t and this will also be h prime t. So, h t value will be equal to 0.6476 that is CRK lower bound is 0.6476.

Let us consider say unbiased estimator here. In this case an unbiased estimator for theta is in the exponential distribution; if I take the mean here mean of this distribution is 1 plus theta that is expectation X is equal to 1 plus theta. Therefore, expectation of x minus 1 will be equal to theta. So, an unbiased estimator will be equal to X minus 1, what is variance of this? That is variance of X that is equal to again same 1 it is of course, bigger than the CRK lower bound here.

(Refer Slide Time: 24:41)

$$\lim_{t \rightarrow \infty} I(t) = \lim_{t \rightarrow \infty} \frac{1}{t^2} = \lim_{t \rightarrow \infty} \frac{1}{t^2} = \frac{1}{t^2}$$

$$I(t) = \frac{t \{ (2-t) e^{t-2} \}}{(e^t - 1)^2} < 0 \text{ for } t \geq 2$$

$$> 0 \text{ for } t \leq 1$$

$$I(t) \text{ changes sign between } 1 \text{ \& } 2. \text{ We numerically solve}$$

$$(2-t) e^t = 2, \text{ to get } t = 1.59362$$

$$\text{At this point } I(t) = 0.6476$$

$$\text{CRKLB is } 0.6476.$$

$$\text{In this case an unbiased estimator for } \theta \text{ is } T = X - 1.$$

$$\text{Var}(T) = \text{Var}(X) = 1 > 0.6476$$

So, here we are able to obtain a non trivial lower bound for the variance of an unbiased estimator and in this problem we are showing that it is not attend here. In fact, we can show that x minus 1 is minimum variance unbiased estimator by a direct argument, that we will take up little later.

Now, in these two examples that I have given here the regularity conditions which are mentioned in the Frechet Rao Cramer lower bound or the Bhattacharya lower bound they were not satisfied. Now there is an interesting question that if those conditions are satisfied and we find FRC lower bound as well as CRK lower bound, then which one will be sharper? The answer is interesting here I will show it through one example.

(Refer Slide Time: 25:30)

Example: Both FRC & CRK LB's can be found.

$X \sim N(\theta, 1)$ . In this case FRC LB for estimating  $\theta$  is 1 ( $E(X)=\theta, V(X)=1$ ), which is attained.

$f(x, \theta) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\theta)^2}, x \in \mathbb{R}$

$f(x, \phi) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\phi)^2}, x \in \mathbb{R}$

$\frac{f(x, \phi)}{f(x, \theta)} = e^{\frac{(\theta^2 - \phi^2)}{2}} e^{(\phi - \theta)x}, x \in \mathbb{R}$

$E_{\theta} \left\{ \frac{f(x, \phi)}{f(x, \theta)} \right\} = e^{\frac{(\theta^2 - \phi^2)}{2}} E_{\theta} \left\{ e^{(\phi - \theta)X} \right\}$

$= e^{\frac{(\theta^2 - \phi^2)}{2}} M_X(\phi - \theta)$  where  $X \sim N(\theta, 1)$

$= e^{\frac{(\theta^2 - \phi^2)}{2}} e^{(\phi - \theta)\theta + \frac{1}{2}(\phi - \theta)^2}$

Here both FRC and CRK lower bounds can be found.

Let me take a simple case normal distribution with mean  $\theta$  and variance unity, suppose we have an observation  $X$  from this distribution. In general we have calculated that if  $X$  follows normal  $\mu$   $\sigma^2$ , the FRC lower bound was  $\sigma^2$  by  $N$ . Now if  $\sigma^2$  I have taken to be 1 then it will become 1 by  $N$ , now that is when we have  $N$  observations  $X_1, X_2, \dots, X_N$  here we have only one observation. So, it will become simply 1. So, in this case FRC lower bound for estimating  $\theta$  is 1 and of course, you had expectation  $X$  is equal to  $\theta$  and variance of  $X$  is equal to 1.

So, it is attained, let us calculate the CRK lower bound here. So, if you want to calculate the CRK lower bound we need to write down the density  $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\theta)^2}$ . We also write this density at another point  $\phi$   $\frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\phi)^2}$ , notice here that these are defined for all  $x$ ,  $x$  is on the real line here also  $x$  is on the real line. So, there is no problem in taking the ratio for all the real values.

So, when I write down the ratio here  $e^{-\frac{1}{2}(x-\theta)^2}$  term cancels out and I will be left with  $e^{\frac{(\theta^2 - \phi^2)}{2}}$  into  $e^{(\phi - \theta)x}$ . This is valid for all  $x$  therefore, when I calculate the expectation when the true density is  $\theta$  this is equal to expectation of  $e^{(\phi - \theta)\theta + \frac{1}{2}(\phi - \theta)^2}$ .

Expectation of  $e$  to the power  $\phi$  minus  $\theta$  into  $X$ , now this is when the density of  $X$  is normal  $\theta$  1, now you look at this expression carefully. It is of the form expectation of  $e$  to the power  $t$   $X$  that is the moment generating function of the normal  $\theta$  1 distribution. Now we know that if I have a normal  $\mu$   $\sigma$  a square distribution then the moment generating function at the point  $t$  that is given by  $e$  to the power  $\mu$   $t$  plus half  $\sigma$  a square  $t$  square.

So, in that one we substitute  $t$  is equal to  $\phi$  minus  $\theta$  and  $\sigma$  square is equal to 1 and  $\mu$  is equal to  $\theta$ . So, this is nothing, but  $e$  to the power  $\theta$  a square minus  $\phi$  square by 2 into the moment generating function of  $x$  at the point  $\phi$  minus  $\theta$  where  $x$  follows normal  $\theta$  1. So, this value turns out to be  $e$  to the power  $\theta$  square minus  $\phi$  square by 2 and  $e$  to the power  $\phi$  minus  $\theta$  into  $\theta$  plus half  $\phi$  minus  $\theta$  whole square.

The image shows a handwritten derivation on a blue background. At the top, it states  $E(X) = \theta$ ,  $V(X) = 1$ . Below this, the probability density function  $f(x, \theta) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\theta)^2}$  is written for  $x \in \mathbb{R}$ . The next line shows  $f(x, \phi) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}(x-\phi)^2}$  for  $x \in \mathbb{R}$ . The derivation then shows the ratio  $\frac{f(x, \phi)}{f(x, \theta)} = e^{(\phi-\theta)x - \frac{1}{2}(\phi-\theta)^2}$ . This is then used to calculate the expectation  $E\left\{ \frac{f(x, \phi)}{f(x, \theta)} \right\} = e^{(\phi-\theta)\theta - \frac{1}{2}(\phi-\theta)^2}$ , where  $X \sim N(\theta, 1)$ . The final result is  $e^{(\phi-\theta)\theta + \frac{1}{2}(\phi-\theta)^2}$ .

In a similar way we can calculate the expectation of  $f X \phi$  by  $f X \theta$  whole square.

(Refer Slide Time: 30:03)

$$E\left\{\frac{f(x, \phi)}{f(x, \theta)}\right\}^2 = e^{\theta^2 - \phi^2} \cdot E\left\{e^{2(\phi - \theta)X}\right\}$$

$$= e^{\theta^2 - \phi^2} M_X(2(\phi - \theta)), \quad \text{where } X \sim N(\theta, 1)$$

$$= e^{\theta^2 - \phi^2} \cdot e^{2(\phi - \theta)\theta + 2(\phi - \theta)^2}$$

$$A(\phi, \theta) = e^{(\phi - \theta)^2 - 1}$$

$$\text{CRKL B} = \lim_{\phi \rightarrow \theta} \frac{(\phi - \theta)^2}{e^{(\phi - \theta)^2 - 1}} = \lim_{t \rightarrow 0} \frac{2t}{e^t - 1} = 1 \text{ attained as } t \rightarrow 0.$$

So, this will become equal to expectation of this square, now if I square a I get here e to the power theta square minus phi square which is a constant term. So, it will come out of the expectation sign and then I will get expectation of e to the power twice phi minus theta x. So, this is equal to e to the power theta a square minus phi square into expectation of e to the power twice phi minus theta into x. So, this is nothing, but again of the form of the moment generating function of x at the point twice phi minus theta. So, this is equal to moment generating function of x at the point twice phi minus theta, where X is a normal theta 1 random variable.

So, we substitute in the formula for the moment generating function and we get it as e to the power twice phi minus theta into theta plus twice phi minus theta whole square. So, naturally now the variance that is A phi theta term is equal to e to the power. So, this term minus a square of this term if I square rate this I get e to the power theta square minus phi square which is the same term here. Similarly here I have e to the power twice phi minus theta into theta and here if I square it I get e to the power phi minus theta theta twice.

So, these terms can be taken out and if you take it out what you get here, twice phi theta minus twice theta a square plus theta a square that cancels out minus phi square and if you look at this term here, here I can take some phi minus theta whole square out. So, phi square will come here which will cancell with this and then you get plus theta a

square which will again cancel plus  $\theta^2$  minus twice  $\theta^2$  plus  $\theta^2$  square. So, all of these terms get cancelled out, you get minus twice  $\phi\theta$  plus twice  $\phi\theta$ .

So, you are left with only  $e$  to the power  $\phi - \theta^2 - 1$ . Now the CRK lower bound is equal to supremum of  $\phi$ , supremum over  $\phi$   $\phi - \theta^2$  square divided by  $e$  to the power  $\phi - \theta^2 - 1$  this you can simply write something like  $t$ . So, it is equal to supremum  $e$  to the power  $t^2$  divided by  $e$  to the power  $t^2 - 1$  where  $t$  is an. Now the analysis of maximization of this is simple in fact, this is a positive term and you can easily show that the maximum is attained at  $t$  is equal to 0.

Now, at  $t$  is equal to 0 this is having 0 by 0 form. So, you take the limit, this is attained as  $t$  tends to 0. Now you notice here in this particular problem the Frechet Rao Cramer lower bound was 1, the variance of the unbiased estimator  $X$  was 1 and the Chapman Robbins Kiefer lower bound is also equal to 1. So, in general we cannot say that CRK bound is worse because it does not take care of the regularity conditions. So, in this particular case for example, we get exactly the same.
