**Sufficiency and Information – I**

In the previous class I have explained the concept of Sufficiency; this concept is the concept which is called the principle of data reduction. So, we have a random sample  $X_1, X_2, \dots, X_n$ , but if we have a sufficient statistic  $t$  then that is sufficient that gives the complete information about the parameter which is contained in the sample. So, we did not retain it. We have given one theorem which is called factorization theorem and this is useful for deriving sufficient statistics in various probability models.

Yesterday I have discussed the normal probability model and I have shown you that how if we change the parameter space; that means, whether we have  $\mu$  known or  $\sigma^2$  known or both are unknown, in each of the cases the sufficient statistics changes. So, sufficiency is the property of the probability model under consideration; let me explain it through few more examples.

Lecture 13  
 Applications of Factorization Theorem (Continued)

Examples: 1. Let  $X_1, \dots, X_n \sim \lambda e^{-\lambda x}$ ,  $x > 0, \lambda > 0$

$$f(\underline{x}, \lambda) = \prod_{i=1}^n f(x_i, \lambda) = \lambda^n e^{-\lambda \sum x_i}$$

$$= g(\sum x_i, \lambda) h(\underline{x}) \rightarrow 1$$

So by FT,  $\sum X_i$  is sufficient.

2. Let  $X_1, \dots, X_n \sim \begin{cases} \theta - x & x > \theta \\ 0 & \text{e.w.} \end{cases}$

The joint density of  $X_1, \dots, X_n$  is

$$f(\underline{x}, \theta) = \begin{cases} e^{n\theta - \sum x_i} & x_i > \theta, i=1, \dots, n \\ 0 & \text{e.w.} \end{cases} = e^{-\sum x_i} e^{n\theta} \cdot I_{(\theta, \infty)}(\sum x_i) \prod_{i=1}^n I_{(\theta, \infty)}(x_i)$$

$$= g(\sum x_i, \theta) h(\underline{x}), \text{ where } h(\underline{x}) = e^{-\sum x_i} \prod_{i=1}^n I_{(\theta, \infty)}(x_i)$$

(1)  
 are order statistics of  $x_1, \dots, x_n$

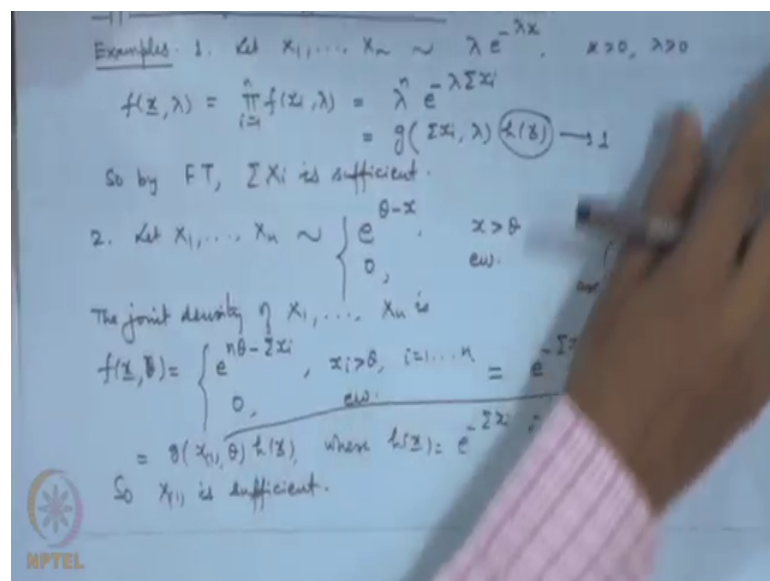

And we will use the concept of this factorization theorem here, let me start with exponential distribution let  $X_1, X_2, \dots, X_n$  follow exponential distribution say with parameter  $\lambda$ .

So, in the factorization theorem we need to write down the joint density of  $X_1, X_2, \dots, X_n$  that is equal to  $\lambda^n e^{-\lambda \sum x_i}$ . Now this whole thing we can write as a function of  $\sum x_i$  and  $\lambda$ ; this  $h(x)$  I am taking to be 1 itself the constant. So, you can see by factorization theorem, by factorization theorem  $\sum x_i$  is sufficient. Let us consider another exponential model in which in place of a scale parameter we will have a location parameter.

So, let us consider say  $X_1, X_2, \dots, X_n$  following exponential say  $\theta - x$ , where  $x$  is greater than  $\theta > 0$  elsewhere. Now in this case the joint density of  $X_1, X_2, \dots, X_n$  is  $f(x, \theta)$  that is equal to  $e^{-\sum x_i / \theta}$ . However, this description of  $x_i > \theta$  also plays a role here, now if we want to write it as a product here we will make use of the indicator function. So, we can write it like this  $e^{-\sum x_i / \theta} \prod_{i=1}^n I(x_i > \theta)$  and indicator function of other  $x_i$ 's from 2 to  $n$  from  $x_1$  to infinity.

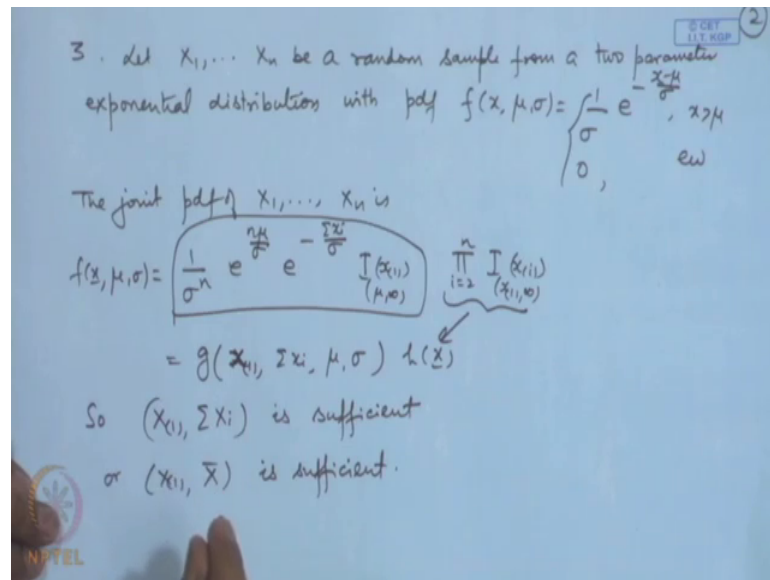

So, what we can consider we can write it as  $g(\sum x_i, \theta) h(x)$ , where  $h(x)$  I am writing as  $\prod_{i=2}^n I(x_i > \theta)$ . So, here this  $x_1, x_2, \dots, x_n$  they are denoting the order statistics of  $x_1, x_2, \dots, x_n$ . So,  $g$  is this function, this is a function of  $\sum x_i$  and  $\theta$ . So, we conclude that  $\sum x_i$  is so,  $\sum x_i$  is sufficient.

(Refer Slide Time: 04:49)

Now, note here when we had lambda as the parameter and here we had a scale model the sufficient statistic was  $\sum x_i$ , although here again we are dealing with exponential distribution, but the nature of the parameter has changed. And therefore, the sufficient statistic is now the minimum of the observations.

(Refer Slide Time: 05:23)

Now in a similar way let us take up the two parameters exponential distribution let us take  $X_1, X_2, \dots, X_n$  be a random sample from a two parameter exponential distribution; say with density function  $f(x, \mu, \sigma) = \frac{1}{\sigma} e^{-\frac{x-\mu}{\sigma}}$  for  $x > \mu$  and it is equal to 0 otherwise. So, once again the joint probability density function of  $X_1, X_2, \dots, X_n$  this is now  $\frac{1}{\sigma^n} e^{-\frac{\sum x_i}{\sigma}} e^{-\frac{n\mu}{\sigma}}$ . And, once again the condition that each of  $x_i$  is greater than  $\mu$  I can express in terms of the indicator function like  $x_1$  is from  $\mu$  to infinity and  $x_i$  is other  $x_i$  is they are from  $x_1$  to infinity  $i$  is equal to 2 to n.

So, this portion I can write as  $g(x_{(1)}, \sum x_i, \mu, \sigma)$  and this part is  $h(x)$ . So, here we conclude that  $X_{(1)}$  and  $\sum X_i$  is sufficient or we can also say  $X_{(1)}$  and  $\bar{X}$  because this is a 1 to 1 function of this is sufficient. I also want to mention here we have earlier considered the maximum likelihood estimators; now let us remember our maximum likelihood estimators for each of these problems for example, in this case the

maximum likelihood estimator for lambda was  $1/\bar{x}$  which is the function of  $\sum x_i$ .

In this particular case the maximum likelihood estimator was  $x_1$  that is a minimum of observations and it is sufficient here. Similarly here you see the maximum likelihood estimator for mu and sigma where  $X_1$  and  $\bar{X} - X_1$  respectively which is again a 1 to 1 function of  $X_1, \bar{X}$  that is a sufficient statistics. So, we can observe that the maximum likelihood estimator if it exists is actually a function of the sufficient statistics.

The reason is obvious because in the factorization theorem we are writing down the density as a function of the parameter and the sufficient statistics into a function which is free from the parameter. Now in the method of maximum likelihood estimator we are maximizing the density function or the mass function with respect to the parameter. Now, the part of the density which contains the parameter contains the variable only through the sufficient statistics. Therefore, the maximization problem will give a solution in terms of the sufficient statistics alone.

(Refer Slide Time: 09:19)

If maximum likelihood estimators exist, they are functions of sufficient statistics.

Examples:  $X_1, \dots, X_n$  a random sample from double exponential dist<sup>n</sup>.  $\frac{1}{2} e^{-|x-\theta|}$ ,  $x \in \mathbb{R}, \theta \in \mathbb{R}$

The joint pdf of  $X_1, \dots, X_n$  is

$$f(\underline{x}, \theta) = \frac{1}{2^n} e^{-\sum_{i=1}^n |x_i - \theta|} = \frac{1}{2^n} e^{-\sum_{i=1}^n |x_i - \theta|} = \frac{1}{2^n} g(\underline{x}, \theta)$$

So  $(X_1, \dots, X_n)$  is sufficient

order statistics

$\hat{\theta}_{ML} = \text{Median}$  ( $\rightarrow$  a function of order statistics)

So, we have a general comment here that if maximum likelihood estimators exist they are functions of sufficient statistics. Let us take some more examples here say for example;  $X_1, X_2, \dots, X_n$  a random sample from double exponential distribution  $\frac{1}{2} e^{-|x-\theta|}$  where  $x$  is any real number  $\theta$  is any real number. In

this case if we considered the sufficiency. So, the joint distribution of  $X_1, X_2, \dots, X_n$  that is equal to  $\frac{1}{2^n} e^{-\sum_{i=1}^n x_i - n\theta}$  is equal to  $\frac{1}{2^n} e^{-\sum_{i=1}^n x_i - n\theta}$ . Now here you observe I cannot reduce it further as a function of parameter and another variable here.

Because each of the  $x_i$ 's are appearing in the modulus sign and therefore, I cannot separate it out. At the most I can consider the reduction as  $\frac{1}{2^n} e^{-\sum_{i=1}^n x_i - n\theta}$ . So, this function is now a function of the order statistics and  $\theta$  and this we can call  $h(x)$ . So, we conclude that the order statistics  $X_1, X_2, \dots, X_n$  is sufficient this order statistic. Now, remember here for this problem what was the maximum likelihood estimator? The maximum likelihood estimator was median of the observations.

And median is a function of this is a function of order statistics because, if we have an odd number of observations say  $2m + 1$  then  $x_{m+1}$  that is the middle of the observation was the median. And, if we have an even number of observations that is  $2m$  then any number between  $x_m$  and  $x_{m+1}$  and we can actually consider say the middle of the 2 that is  $\frac{x_m + x_{m+1}}{2}$  as the maximum likelihood estimator. So, this is a function of order statistics in this case also.

So, this statement is true in general. Another thing which I just now pointed out that many times when we are writing down the density function say in this case we are, we have to incorporate the region of the variable which is dependent upon the parameter as a part of the joint density function. Because, if you do not included it then we cannot decide a sufficient statistic for example, if he had written only this part then, there is no sufficient statistics here because  $e^{-\sum_{i=1}^n x_i - n\theta}$  can be separately written  $e^{-\sum_{i=1}^n x_i}$   $e^{-n\theta}$  can we separately written.

However, this is not a complete description of the density unless we include the region  $x_i > \theta$  for all  $i$  and this is the way of including this. A similar phenomena is observed in the uniform distributions also like in the uniform distribution the range is dependent upon the range of the variable is dependent upon the parameter.

(Refer Slide Time: 13:43)

Let  $x_1, \dots, x_n \sim U(0, \theta), \theta > 0$

$$f(x, \theta) = \begin{cases} \frac{1}{\theta^n}, & 0 < x_i < \theta, \quad i=1, \dots, n \\ 0, & \text{ew} \end{cases}$$

$$= \frac{1}{\theta^n} I(x_{(n)} | (0, \theta)) \prod_{i=1}^{n-1} I(x_i | (0, x_{(n)}))$$

$x_{(n)}$  is sufficient. So  $(x_{(1)}, x_{(n)})$  is sufficient

$x_1, \dots, x_n \sim U(\theta - \frac{1}{2}, \theta + \frac{1}{2})$

$$f(x, \theta) = \begin{cases} 1, & \theta - \frac{1}{2} < x_{(1)} \leq \dots \leq x_{(n)} < \theta + \frac{1}{2} \\ 0, & \text{ew} \end{cases} = I(x_{(1)} | (\theta - \frac{1}{2}, \theta + \frac{1}{2})) I(x_{(n)} | (\theta - \frac{1}{2}, \theta + \frac{1}{2})) \prod_{i=2}^{n-1} I(x_i | (x_{(1)}, x_{(n)}))$$

So, let us consider say  $X_1, X_2, \dots, X_n$  say a random sample from uniform  $0$  to  $\theta$  distribution. Now in this case the joint density is equal to  $1/\theta^n$  if  $0 < x_i < \theta$  and it is equal to  $0$  elsewhere. So, this part we will express as  $1/\theta^n I(x_{(n)} | (0, \theta))$  and the other  $x_i$ 's are from  $0$  to  $x_{(n)}$  for  $i = 1$  to  $n - 1$ . So, you can see this portion we can express as  $g(x_{(n)}, \theta) \cdot h(x)$ .

So,  $X_{(n)}$  is sufficient; however, if we consider say uniform distribution which is on a 2-sided interval here we have taken one side as  $0$ ; suppose we consider say from  $\theta - 1/2$  to  $\theta + 1/2$ . In this case the joint distribution is simply  $1$  because,  $\theta + 1/2 - (\theta - 1/2) = 1$ . However, each of the  $x_i$ 's they are between  $\theta - 1/2$  and  $\theta + 1/2$ . So, this part then we can incorporate as indicator function of  $x_{(1)}$  from  $\theta - 1/2$  to  $\theta + 1/2$  and the indicator function of  $x_{(n)}$  from  $\theta - 1/2$  to  $\theta + 1/2$ .

And the remaining order statistics line between  $x_{(1)}$  and  $x_{(n)}$   $i = 2$  to  $n - 1$ . So, this you can see it is a function of  $x_{(1)}, x_{(n)}, \theta$  into  $h(x)$  this part is  $h(x)$ , this part is a  $h(x)$  and this part is a function of  $x_{(1)}, x_{(n)}$  and  $\theta$ . So, here  $X_1, \dots, X_n$  is sufficient although the parameter remains 1 dimensional here, but the order statistics contains 2 terms. If you remember the maximum likelihood estimator; the maximum likelihood estimator for this problem was any value between  $x_{(n)} - 1/2$  to  $x_{(1)} + 1/2$  so, which is the function

of  $X_1, \dots, X_n$ . So, the statement that the maximum likelihood estimators if they exist they are functions of the sufficient statistics is satisfied here also.

So, these are the topics that I will be covering in the next lecture.
