Lecture – 29
UMVU Estimation, Ancillarity – I

In the last lecture, I introduced the concept of minimal sufficiency and completeness of certain statistics or again these are also the properties of the family of distributions.

(Refer Slide Time: 00:40)

Now, before we proceed further I will define a related concept that is called boundedly complete, boundedly complete statistics or boundedly complete family of distributions. So, we say that P is equal to P_θ is a boundedly complete family of distributions. If expectation of $g(X)$ is equal to 0 for all θ and g bounded implies that probability of $g(X)=0$ is 1 for all θ .

So, the difference from the definition of completeness is that there we wrote any function g . So, expectation $g(X)$ equal to 0 for all θ and any function g if that implies that the probability that the function is 0 with probability 1 then it was complete. If I impose the condition that g is bounded, then it will imply that probability of $g(X)=0$ is 1 then it will be called a boundedly complete family of distributions. So, we can say that completeness implies bounded completeness. However, the converse is not true I will give an example here.

Let X be a random variable with probability mass function given by $P_\theta(X = x) = (1-\theta)^x \theta$ for $x = 0, 1, 2, \dots$ and so on. And $P_\theta(X = -1) = \theta$ here θ is between 0 to 1. Now, you can easily see that $\theta + \sum_{x=0}^{\infty} (1-\theta)^x \theta = 1$ because this is infinite geometric series with common ratio θ . So, this cancels out you get to 1.

So, this is a proper probability distribution. You can say it is a shifted geometric kind of distribution. Let us show whether it is complete or not ok.

(Refer Slide Time: 04:07)

Let $E_\theta h(X) = h(-1)\theta + \sum_{x=0}^{\infty} h(x)(1-\theta)^x \theta = 0 \quad \forall \theta \in (0,1)$

$\Rightarrow \sum_{x=0}^{\infty} h(x)\theta^x = -\frac{h(-1)\theta}{(1-\theta)^2} \quad \forall \theta \in (0,1)$

$= -h(-1)\theta [1 + 2\theta + 3\theta^2 + \dots]$

Equating the coefficients of the power series on both the sides, we get

$h(x) = -x h(-1) \quad , \quad x = 0, 1, 2, \dots$

If $h(-1)$ is bounded (then $h(-1)$ must be 0)

$\Rightarrow h(x) = 0 \quad \forall x$

$P_\theta(h(X)=0) = 1 \quad \forall \theta \in (0,1)$ So h is boundedly complete.

But if $h(-1) \neq 0$, then $h(x) \neq 0$

$\Rightarrow P_\theta(h(X)=0) \neq 1$

So h is not complete.

So, consider a function $h(X)$ then its expectation can be written as $h(-1)\theta + \sum_{x=0}^{\infty} h(x)(1-\theta)^x \theta = 0$ for all θ in the interval 0 to 1. Now this term I take to the right hand side and then we divide by $1 - \theta^2$. So, it is reducing to $h(X)$ in to θ^x , it is equal to $-h(-1)\theta / (1-\theta)^2$ this is for all θ then the interval 0 to 1.

Further, this $1 - \theta^2$ in the denominator. So, if I bring it to the numerator it becomes $1 - \theta^2$ and I can expand because θ is in the interval 0 to 1. So, this we can write as $1 - \theta^2 = (1-\theta)(1+\theta)$ and this expansion can be written as $1 + 2\theta + 3\theta^2 + \dots$ and so on. Now, if I consider these 2

terms, the left hand side is a power series in theta and the right hand side is also a power series in theta. So, if I create the terms we get equating the coefficients of the power series on both the sides, we get $h(X)$ is equal to θ^{-1} for x equal to $0, 1, 2, 1$ so on.

Now if θ^{-1} is bounded then θ^{-1} must be 0 because if θ^{-1} is not 0 then this function is unbounded, because it will be X into some constant. So, for boundedness the only possibility is that θ^{-1} is 0 which will imply $h(X)$ is equal to 0 for all x . That means, probability of $h(X)$ is equal to 0 will be 1 for all theta and the interval 0 to 1. So, h is boundedly complete not X is boundedly complete. But if θ^{-1} is not 0 then $h(X)$ is also not 0 this implies probability that $h(X)$ is 0 cannot be 1. So, h is not complete because expectation of $h(X)$ is 0, but $h(X)$ will not be 0 with probability 1.

So, this is an example of a boundedly complete family of distributions which is not complete.

(Refer Slide Time: 07:52)

Example $X_1, \dots, X_n \sim U(0, \theta), \theta > 0$

$X_{(n)}$ is minimal sufficient. We prove that $X_{(n)}$ is complete.

$$f_{X_{(n)}}(x) = \begin{cases} \frac{n x^{n-1}}{\theta^n}, & 0 < x < \theta. \\ 0, & \text{ew.} \end{cases}$$

$$E_{\theta} g(X_{(n)}) = 0 \quad \forall \theta > 0 \Rightarrow \int_0^{\theta} g(x) \frac{n x^{n-1}}{\theta^n} dx = 0 \quad \forall \theta > 0$$

$$\Rightarrow \int_0^{\theta} g^*(x) dx = 0 \quad \forall \theta > 0$$

$$\Rightarrow g^*(x) = 0 \text{ a.e.} \Rightarrow g(x) = 0 \text{ a.e. on } (0, \infty)$$

$$\Rightarrow P_{\theta}(g(X_{(n)}) = 0) = 1 \quad \forall \theta > 0.$$

So $X_{(n)}$ is a complete statistic.

Now, there are relationships between sufficiency and completeness also there is a general way of determining complete statistics. For example, if the distributions are in the exponential family I have already given the example of binomial distribution Poisson distribution. So, in the Poisson distribution family is complete. If I consider sufficient statistics or minimal sufficient statistics, that is running out to be $\sum x_i$ which is again

having Poisson distribution with parameter $n\lambda$. So, if Poisson λ is complete, Poisson $n\lambda$ is also complete.

So, $\sum x_i$ is complete. So, we can conclude that in most of the standard examples that we have discussed the corresponding sufficient or minimal sufficient statistics will also be complete. Let me just take the example of non regular family say; let me consider say X_1, X_2, \dots, X_n following uniform $0, \theta$ distribution then $\sum X_i$ is minimal sufficient we prove that $\sum X_i$ is complete. Let us consider the distribution of $\sum X_i$ that is $n x$ to the power $n - 1$ by θ to the power n $0 < x < \theta$ it is 0 elsewhere.

So, if I consider expectation of say g of $\sum X_i$ is equal to 0 for all θ then this statement is equivalent to $\int_0^\theta g(x) n x^{n-1} \theta^{-n} dx = 0$ for all θ . Now, this is equivalent to saying a function of x over all the intervals 0 to θ is integrated to 0. Again by the Lebesgue integration theory it implies that g must be 0 almost everywhere this g star function I have taken to be this. So, this implies that $g(\sum X_i)$ is equal to 0 almost everywhere on 0 to infinity. This implies that probability that $g(\sum X_i)$ is equal to 0 is 1 for all θ . So, $\sum X_i$ is a complete a statistic.

So, there is a relation between minimal sufficiency and complete sufficiency. In fact, we have the following theorem.

(Refer Slide Time: 11:04)

Theorem: If $T(X)$ is complete and sufficient, then $T(X)$ is minimal sufficient.

Remark: The converse of the above is not true.

Example of minimal sufficient st. which is not complete

$X_1, \dots, X_m \sim N(\mu, \sigma_1^2)$
 $Y_1, \dots, Y_n \sim N(\mu, \sigma_2^2)$ $\sigma_1^2 \neq \sigma_2^2$

The joint pdf of $(X_1, \dots, X_m, Y_1, \dots, Y_n)$ is

$$f(x, y, \mu, \sigma_1^2, \sigma_2^2) = \frac{1}{(\sqrt{2\pi})^{m+n} \sigma_1^m \sigma_2^n} e^{-\frac{1}{2\sigma_1^2} \sum (x_i - \mu)^2 - \frac{1}{2\sigma_2^2} \sum (y_j - \mu)^2}$$

$$= \frac{1}{(\sqrt{2\pi})^{m+n} \sigma_1^m \sigma_2^n} e^{-\frac{\sum x_i^2}{2\sigma_1^2} + \frac{m\mu \sum x_i}{\sigma_1^2} - \frac{m\mu^2}{2\sigma_1^2} - \frac{\sum y_j^2}{2\sigma_2^2} + \frac{n\mu \sum y_j}{\sigma_2^2} - \frac{n\mu^2}{2\sigma_2^2}}$$

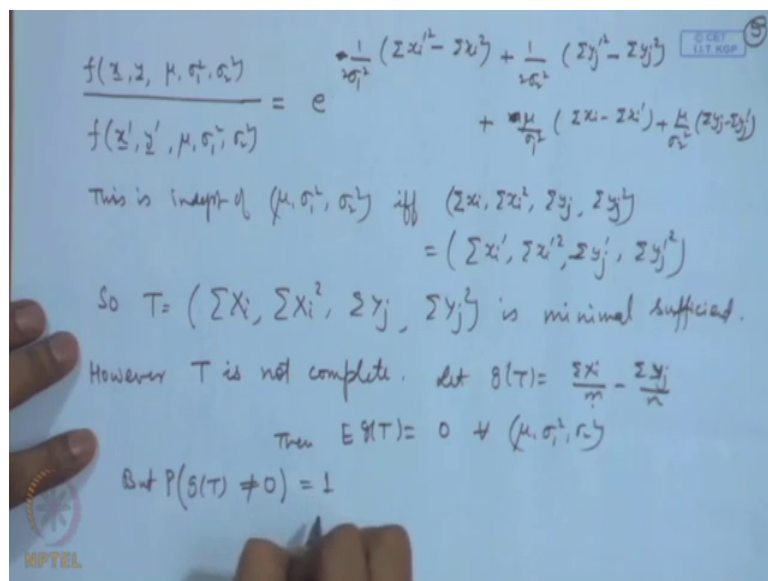

$\theta_1 = -\frac{1}{2\sigma_1^2}, \theta_2 = \frac{\mu}{\sigma_1^2}, \theta_3 = -\frac{1}{2\sigma_2^2}, \theta_4 = \frac{\mu}{\sigma_2^2}$

If $T(X)$ is complete and sufficient then $T(X)$ is minimal sufficient. However, the converse of the above statement is not true that is we may have an example of say minimal sufficient statistic which is not complete. Let us take say X_1, X_2, \dots, X_m a random sample from normal with mean μ and variance σ_1^2 and Y_1, Y_2, \dots, Y_n . This is another independent sample from normal with mean μ and variance σ_2^2 ; here σ_1^2 and σ_2^2 are different.

Let us consider the joint distribution of X_1, X_2, \dots, X_m and Y_1, Y_2, \dots, Y_n . The joint pdf of $X_1, X_2, \dots, X_m, Y_1, Y_2, \dots, Y_n$ that is equal to $\frac{1}{(2\pi)^{\frac{m+n}{2}}}$ to the power $m+n$ σ_1^2 to the power n σ_2^2 to the power n $e^{-\frac{1}{2\sigma_1^2} \sum_{i=1}^m (x_i - \mu)^2 - \frac{1}{2\sigma_2^2} \sum_{j=1}^n (y_j - \mu)^2}$. This we can simplify as $\frac{1}{(2\pi)^{\frac{m+n}{2}}}$ to the power $m+n$ σ_1^2 to the power n σ_2^2 to the power n $e^{-\frac{1}{2\sigma_1^2} \sum_{i=1}^m x_i^2 - \frac{m\mu}{\sigma_1^2} \bar{X} - \frac{1}{2\sigma_1^2} \sum_{i=1}^m \mu^2 - \frac{1}{2\sigma_2^2} \sum_{j=1}^n y_j^2 - \frac{n\mu}{\sigma_2^2} \bar{Y} - \frac{1}{2\sigma_2^2} \sum_{j=1}^n \mu^2}$.

So, if we apply the ratio by writing down this joint pdf at 2 points x, y and say x' , y' then these terms will get cancelled out and we will be left with $\frac{\sum_{i=1}^m x_i^2 - \sum_{i=1}^m x_i'^2}{2\sigma_1^2} + \frac{\sum_{j=1}^n y_j^2 - \sum_{j=1}^n y_j'^2}{2\sigma_2^2}$ in 2 parametric function $\bar{X} - \bar{Y}$ into the parametric function, $\bar{X} - \bar{X}'$, $\bar{Y} - \bar{Y}'$ and $\sum_{i=1}^m x_i^2 - \sum_{i=1}^m x_i'^2$ and $\sum_{j=1}^n y_j^2 - \sum_{j=1}^n y_j'^2$.

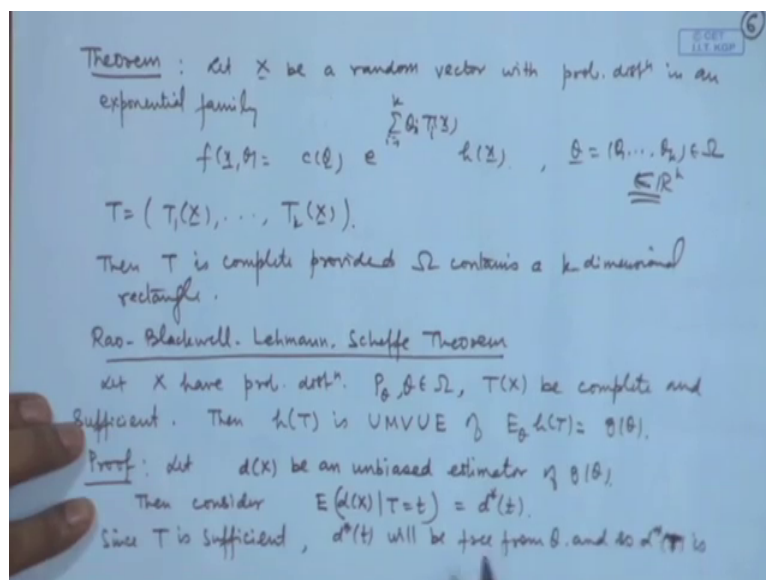

(Refer Slide Time: 15:03)

So, if we write down this function here say $f(x, y) = \frac{\mu \sigma_1^2 \sigma_2^2}{\sigma_1^2 \sigma_2^2} \frac{\sigma_1^2 \sigma_2^2}{\sigma_1^2 \sigma_2^2}$ then that is equal to $e^{-\frac{1}{2} \sigma_1^2 (x - \mu)^2 - \frac{1}{2} \sigma_2^2 (y - \mu)^2}$ or $e^{-\frac{1}{2} \sigma_1^2 x^2 - \frac{1}{2} \sigma_2^2 y^2 + \mu \sigma_1^2 x + \mu \sigma_2^2 y - \frac{1}{2} \sigma_1^2 \mu^2 - \frac{1}{2} \sigma_2^2 \mu^2}$. So, this is independent of μ if and only if we have $\sigma_1^2 x^2 + \sigma_2^2 y^2 = \sigma_1^2 x'^2 + \sigma_2^2 y'^2$ and $\sigma_1^2 x'^2 + \sigma_2^2 y'^2 = \sigma_1^2 x^2 + \sigma_2^2 y^2$.

So, T is equal to $\sigma_1^2 x^2 + \sigma_2^2 y^2$ is minimal sufficient. However, T is not complete. Let us consider $g(T)$ as a $\sigma_1^2 x^2 + \sigma_2^2 y^2$ by n . Then expectation of $g(T)$ is equal to 0 for all μ because expectation of x^2 and expectation of y^2 is μ^2 . So, it is μ^2 by n . But $g(T)$ is not 0; actually probability that $g(T)$ is not 0 is 1, probability that $g(T)$ is equal to 0 is actually 0. So, T is not complete. So, this is an example of a minimal sufficient statistic which is not complete. To determine complete statistics in general settings or to prove the completeness in general settings of exponential family one only needs to check the kind of parameter space that we are having.

(Refer Slide Time: 18:14)

So, we have the following general theorem which I will state without proof for the proof one can look at the book of Layman testing of hypothesis book. So, let X be a random

vector with probability distribution in an exponential family. Say we write it in the form $c(\theta) e^{\sum_{i=1}^k \theta_i T_i(x)}$. So, here $c(\theta)$ is a function of parameter θ and $T_i(x)$ is function free from parameter and parameter is occurring in the exponent, here θ is equal to $\theta_1 \theta_2 \dots \theta_k$ that is it is belonging to \mathbb{R}^k . Let me say it belongs to Ω and Ω is a subset of \mathbb{R}^k .

Let us write T as $T_1(X)$ and so on $T_k(X)$. Then T is complete provided Ω contains a k dimensional rectangle. If you look at the previous example here this is actually a 3 parameter distribution here. Here what we are getting is $\frac{1}{\sigma^2} \mu$ or you can say $\frac{1}{\sigma^2} \mu$ by $\frac{1}{\sigma^2}$ then $\frac{1}{\sigma^2}$ and μ by $\frac{1}{\sigma^2}$. However, they are not independent. Actually the parameter is 4 dimensional. If we write θ_1 is equal to say $-\frac{1}{2\sigma^2}$ θ_2 is equal to μ by $\frac{1}{\sigma^2}$ θ_3 as equal to say $-\frac{1}{2\sigma^2}$ and θ_4 is equal to say μ by $\frac{1}{\sigma^2}$ then this is a 4 dimensional parameter.

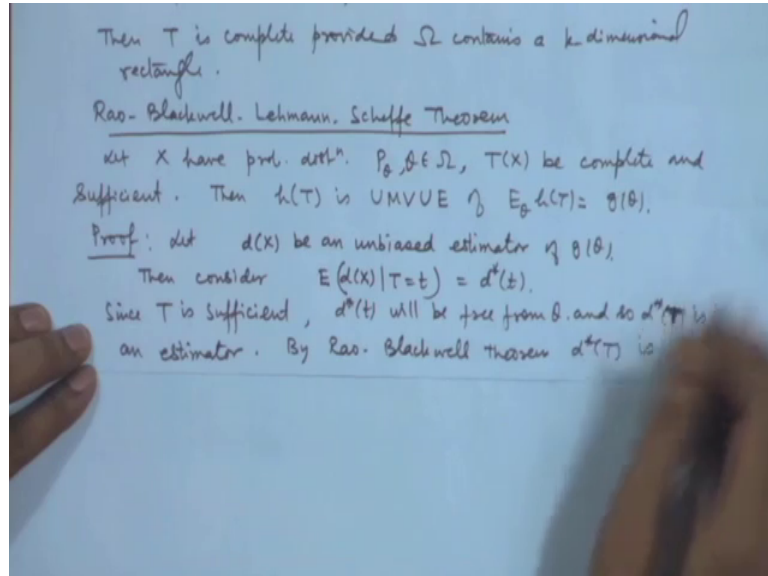

But there is dependency upon that for example, given θ_1 θ_2 and θ_3 we can determine θ_4 . So, the parameter space does not contain a 4 dimensional rectangle and that is why we could actually show that this is not complete T was not complete here. We have seen the application of sufficiency in estimation problems. We saw that if we have an unbiased estimator we can certainly improve upon it by conditioning upon the sufficient statistics, the result was known as the Rao Blackwell theorem. Now, if we couple this concept with the completeness we get a stronger result. In fact, we can reduce the problem to determination of the uniformly minimum variance unbiased estimator; the resulting result which is actually associated in the name of Lehmann Scheffe.

So, I will couple the 2 results Rao Blackwell and Lehmann Scheffe and we call it Rao Blackwell Lehmann Scheffe theorem. Let X have probability distribution P_θ ; θ belonging to say Ω and $T(X)$ be complete and sufficient, then $h(T)$ is UMVUE of expectation of $h(T)$; let us call it say $g(\theta)$. That means, for any estimable unbiased estimate function $g(\theta)$ if I have an unbiased estimator which is dependent upon the complete sufficient statistic then that will be actually UMVUE. Let us look at the proof of this.

Let say $d(X)$ be an unbiased estimator of $g(\theta)$. Then you will have consider expectation of $d(X)$ given T ; let me denote it by say $d^*(t)$. Since, T is sufficient $d^*(t)$ will be free

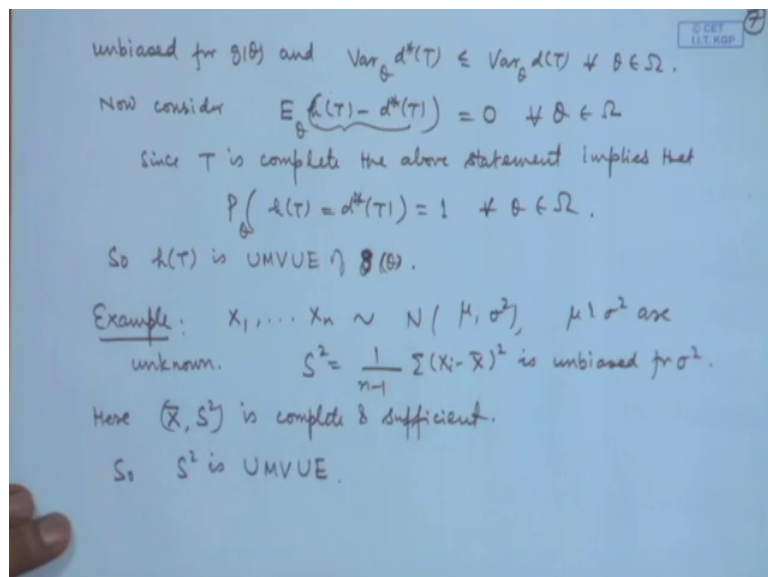

from theta, because the conditional distribution of X given T is independent of theta. Therefore, this expectation will not contain any term of theta and we can call it d star t and so, d star t is d star T suppose I had capital T here, this is an estimator.

(Refer Slide Time: 24:17)

Now, we have already seen that by Rao Blackwell theorem d star T is also unbiased for g theta and variance of d star was less than or equal to the variance of d T.

(Refer Slide Time: 24:38)

Now, consider expectation of h T minus d star T then that is 0 because both of these are unbiased for g theta. Now, this is a function of T and T is complete. Since, T is complete

the above statement implies that $h(T)$ must be equal to $d^*(T)$ with probability 1. Essentially it proves that $h(T)$ is a unique unbiased estimator of $g(\theta)$. So, $h(T)$ is UMVUE.

Actually $g^*(d^*)$ is also UMVUE, but these 2 we differ only on a set of measure 0. Now, this result is extremely useful for finding out the UMVUEs. We have seen actually in the earlier method of lower bounds that many times whatever best unbiased estimator we are able to think of the variance of that is not attaining the lower bound, whether we are considering the Fisher Rao Cramer lower bound, Bhattacharya lower bound or Chapman's Robbins Keifer lower bound etcetera. In many of the cases we saw that the variance of the unbiased estimator was bigger than the lower bound the corresponding lower bound. However, this method when we are considering a function of complete and sufficient statistic, it immediately proves that the corresponding estimator will become uniformly minimum variance unbiased estimator.

Essentially what it is doing? It will actually show that the corresponding unbiased estimator is actually the only unbiased estimator available except of course, on a set of probability 0. So, since it is unique certainly it is UMVUE. So, if we go back to various problems where the lower bound was not attained, for example, if you consider normal μ σ^2 where μ is unknown and we were considering the estimation of σ^2 . So, let us consider say X_1, X_2, \dots, X_n follows normal μ σ^2 μ and σ^2 are unknown and we have this S^2 as $\frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2$ this is unbiased for σ^2 .

Now, in this problem \bar{X} and S^2 is complete and sufficient. So, S^2 is UMVUE. We had noticed here that in this particular case, the lower bound that was attained by the method of Fisher Rao Cramer, it was lower than the variance of S^2 . The variance of S^2 was $\frac{2\sigma^4}{n-1}$ and lower bound was $\frac{2\sigma^4}{n}$, but here in this method UMVUE proving is easy, because we are just looking at the expectation of S^2 , since it is equivalent it is a function of the complete sufficient statistics. So, it becomes UMVUE.

(Refer Slide Time: 28:59)

2. $X_1, \dots, X_n \sim U(0, \theta), \theta > 0$
 $X_{(n)}$ is complete and sufficient
 $E(X_{(n)}) = \int_0^\theta x \cdot \frac{n x^{n-1}}{\theta^n} dx = \frac{n}{n+1} \theta$
 $\Rightarrow E\left(\frac{n+1}{n} X_{(n)}\right) = \theta$
 By R.B.L.S theorem $T = \frac{n+1}{n} X_{(n)}$ is UMVUE for θ .

3. $X_1, \dots, X_n \sim \mathcal{P}(\lambda), \lambda > 0$.
 $\bar{X}, T = \sum X_i$ is complete & sufficient.
 Consider $g(\lambda) = e^{-\lambda} = P(X_1 = 0)$
 Let $d(X_1) = 1$ if $X_1 = 0$
 $= 0$ if $X_1 \neq 0$.

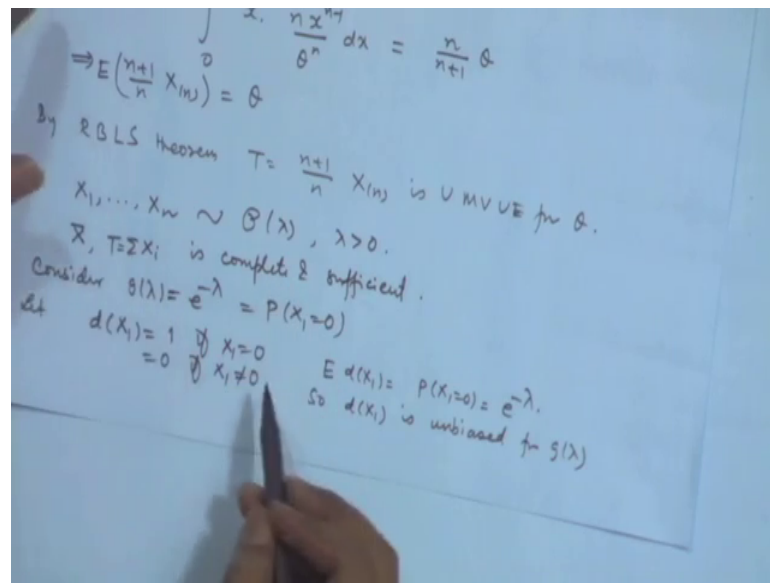

Let us take other related examples also. X_1, X_2, \dots, X_n following uniform $0, \theta$. Here we have shown that $X_{(n)}$ is complete and sufficient.

Now, if we look at expectation of $X_{(n)}$ that is $\int_0^\theta x \cdot \frac{n x^{n-1}}{\theta^n} dx$ then this is equal to $\frac{n}{n+1} \theta$. That means $\frac{n+1}{n} X_{(n)}$ is unbiased for θ . Now, this is a function of complete sufficient statistics. So, by Rao Blackwell Lehmann Scheffe theorem we conclude that $\frac{n+1}{n} X_{(n)}$ this is UMVUE for θ .

We have also seen the standard distributions like Poisson distribution; where for λ we are able to derive the UMVUE, but for λ^2 we are not able to derive or if I can see that $e^{-\lambda}$ then we were not able to derive the UMVUE, but using this method we can derive. Let me explain this here.

Let us consider say X_1, X_2, \dots, X_n following Poisson λ distribution $\lambda > 0$. Now, here \bar{X} or you can say $\sum X_i$ this is complete and sufficient. Suppose I am considering $g(\lambda) = e^{-\lambda}$ which I had explained actually this is probability of $X_1 = 0$ that is the proportion of 0 occurrences in a given problem. Let us define say $d(X_1) = 1$ if $X_1 = 0$ and it is equal to 0 if X_1 is not equal to 0.

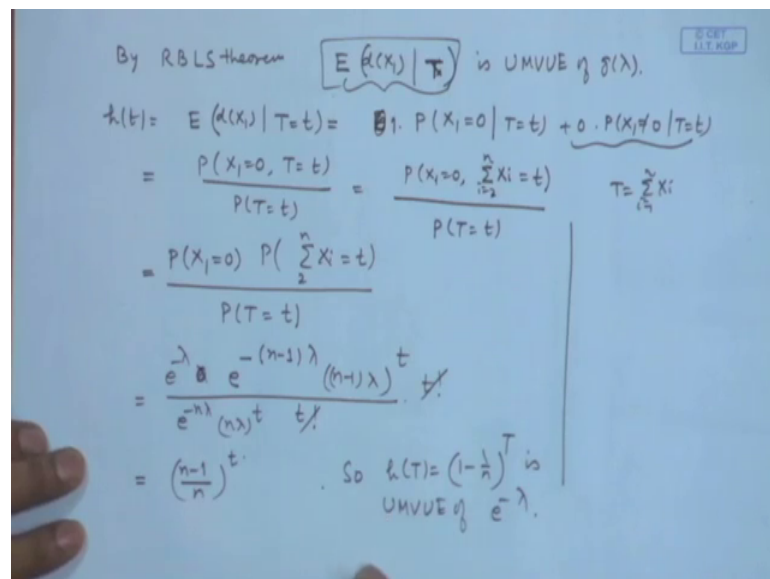

(Refer Slide Time: 31:38)

Then, if I consider here expectation of $d(X_1)$ then that is equal to probability of X_1 is equal to 0 that is equal to $e^{-\lambda}$. So, $d(X_1)$ is unbiased for $g(\lambda)$.

However, this is not UMVUE because this is not a function of the complete sufficient statistic.

(Refer Slide Time: 32:07)

So, if I apply the Rao Blackwell Lehmann Scheffe theorem, if I consider Rao Blackwell Lehmann Scheffe theorem; if I consider expectation of $d(X_1)$ given $T = \sum X_i$ or X

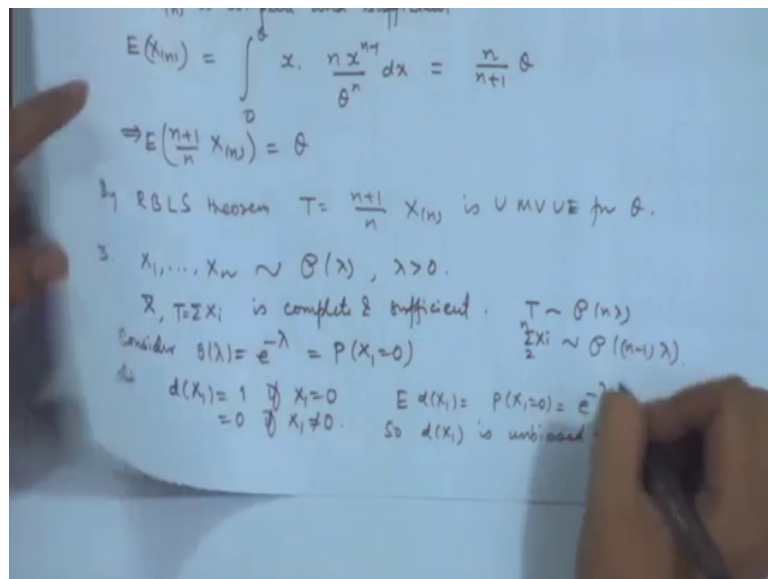

bar we can write then this is UMVUE of $g(\theta)$. So, the only thing remaining is that determination of this function, we can determine it easily.

Let us denote it by $h(T)$, expectation of say $d(X_1)$ given T is equal to $g(t)$. Then this is equal to expectation of now, $d(X_1)$ takes only 2 values 1 and 0. So, it is equal to probability of X_1 is equal to 0 given T is equal to t , because $d(X_1)$ is equal to 0 then probability of X_1 is not equal to 0, but when $u=0$ multiplied then that value will not matter; X_1 not equal to 0 given T is equal to t . So, this term is vanishing.

So, we need to only determine this conditional probability that is probability X_1 is equal to 0; T is equal to t divided by probability T is equal to t that is equal to probability X_1 is equal to 0. Now, this T is nothing but $\sum_{i=1}^n X_i$; i is equal to 1 to n . If I say X_1 is equal to 0 then we can say $\sum_{i=2}^n X_i$ is also equal to t .

Now, here you notice that the sum of independent Poisson's is Poisson.

(Refer Slide Time: 33:58)

So, the distribution of T will be Poisson $n\lambda$ and distribution of $\sum_{i=2}^n X_i$ is equal to t that will be Poisson $n-1\lambda$. So, if we use this here X_1 and $\sum_{i=2}^n X_i$ these will be independent. So, this can be written as the product of this probability. So, it becomes probability of X_1 equal to 0 in to probability of $\sum_{i=2}^n X_i$ is equal to t divided by probability T is equal to t . So, that is equal to $e^{-\lambda}$ to the power $n-1$; so, that term will not come. Then this is

following Poisson $n - 1$ λ . So, it is becoming $e^{-\lambda}$ to the power $n - 1$ λ^n to the power t divided by $t!$ and then probability T is equal to t that is $e^{-\lambda}$ to the power $n - 1$ λ^n to the power t into $t!$.

So, these terms get cancelled out and we are left with $n - 1$ by n . So, $h(T)$ is equal to $1 - 1/n$ to the power of T ; this is UMVUE of $e^{-\lambda}$. So, this Rao Blackwell Lehmann Scheffe theorem is extremely useful to determine the UMVUE for various functions where the method of lower bounds is not applicable. I will be introducing in the next classes.
