Lecture - 40
UMP Tests - IV

In the next lecture, I will be showing that in this case we have to take some restriction on the class of the assets which we call unbiased tests and within that class actually UMP Tests can be derived; so, that we will be taking up in the next lecture. Now let me continue the applications of this monotone likelihood ratio property and the derivation of the UMP test for various distributions.

(Refer Slide Time: 00:49)

So, let me consider uniform distribution. So, we have X_1, X_2, \dots, X_n . This is a random sample from uniform 0 to θ distribution. And if we want to derive the UMP test for one sided testing problems etcetera, we should firstly, have the monotone likelihood ratio property. Let us check whether that is true or not. So, let us write down the joint density of X_1, X_2, \dots, X_n . I write it as $f(x, \theta) = 1/\theta^n$ if each of the x_i is between 0 to θ and it is 0 elsewhere.

Now, we can write in a compact form as we have done when we were considering the discussion of the sufficiency or the maximum likelihood estimator.

(Refer Slide Time: 02:09)

$$f(x, \theta) = \begin{cases} \frac{1}{\theta^n}, & 0 \leq x_1 \leq x_2 \leq \dots \leq x_n \leq \theta \\ 0, & \text{elsewhere} \end{cases}$$

$$= \frac{1}{\theta^n} I_{[0, \theta]}(x_{(n)})$$
 where $(x_1, \dots, x_{(n)})$ are order statistics and $x_{(n)} = \max(x_1, \dots, x_n)$.

$$r(x) = \frac{f(x, \theta_1)}{f(x, \theta_2)} = \begin{cases} \left(\frac{\theta_2}{\theta_1}\right)^n & 0 \leq x_{(n)} \leq \theta_2 & \theta_1 > \theta_2 \\ \infty & \theta_2 < x_{(n)} \leq \theta_1 \end{cases}$$

$r(x)$ is monotonically increasing in $x_{(n)}$.
 So $\{U[0, \theta] : \theta > 0\}$ has MLR in $(\theta, X_{(n)})$.

We can write this as $1/\theta^n$ if $0 \leq x_1 \leq x_2 \leq \dots \leq x_n \leq \theta$ and 0 elsewhere. We further write this as $1/\theta^n$ times the indicator function of the largest order statistic, where $x_{(n)}$ is the maximum of x_1, x_2, \dots, x_n . So, $x_{(n)}$ is actually the largest. So, we can write in terms of this. So, if I consider say $f(x, \theta_1)$ divided by $f(x, \theta_2)$, let me take say $\theta_1 > \theta_2$ then this ratio will become $(\theta_2/\theta_1)^n$ and ratio of the indicator functions.

So, if I choose $x_{(n)}$ to be less than or equal to θ_2 , then both the densities are valid and we will get this indicator function value as 1. If I take $\theta_2 < x_{(n)} \leq \theta_1$ in that case $f(x, \theta_1)$ is a positive density whereas this density becomes 0. So, this becomes infinite. Now if $x_{(n)}$ is greater than θ_1 , then of course, both the densities are 0 and we do not have to write that region. So, what we are observing is this likelihood ratio $r(x)$ is monotonically increasing in $x_{(n)}$. So, we can say this family of uniform distributions. This family has monotone likelihood ratio in θ and $X_{(n)}$ this is our $T(x)$.

Lecture 24

Families with Monotone Likelihood Ratio

$N(\mu, \sigma^2)$ both parameters are unknown

$H_0: \mu = 0$
 $H_1: \mu \neq 0$ } composite

$f(\theta)$ $f(x, \theta)$

$H_0: \theta \leq \theta_0$ $H_1: \theta > \theta_0$
 $H_0: \theta \geq \theta_0$ $H_1: \theta < \theta_0$

Let $f(x, \theta)$ be a prob. m.f (d.f.) of a r.v. X .

$f(x) = f(x, \theta_1)$ $\theta_1 > \theta_2$

© CET
I.I.T. KGP

If you want to apply the monotone likelihood ratio property and the corresponding UMP tests this theory, then this is what we were requiring.

(Refer Slide Time: 04:47)

© CET
I.I.T. KGP

(Lehmann & Romano, 2005, Rohatgi & Saleh.)

Let r.v. X have pmf (pdf) $f(x, \theta)$ with MLR in $(\theta, T(x))$.
 $\theta \in \Theta \subseteq \mathbb{R}$.

For testing $H_0: \theta \leq \theta_0$ against $H_1: \theta > \theta_0$, there exists a Uniformly most powerful (UMP) test, given by

$$\phi(x) = \begin{cases} 1 & \text{if } T(x) > c \\ \gamma & \text{if } T(x) = c \\ 0 & \text{if } T(x) < c \end{cases} \quad \dots (1)$$

where c & γ are determined by

$$E_{\theta_0} \phi(X) = \alpha \quad \dots (2)$$

The power function $P^*(\theta) = E_{\theta} \phi(X)$

© CET
I.I.T. KGP

That if we are looking at the families with MLR in theta T x, then for one sided testing problems, we have the UMP test here. So, we will apply this now. So, let us derive the test in this particular case.

(Refer Slide Time: 05:11)

So we have UMP test for testing

$H_0: \theta \leq \theta_0$ vs $H_1: \theta > \theta_0$.

Reject H_0 if $X_{(n)} \geq C$
 Accept H_0 if $X_{(n)} < C$,

where C is determined by the size condition

$$P(X_{(n)} \geq C) = \alpha$$

$$\int_C^{\theta_0} \frac{n y^{n-1}}{\theta_0^n} dy = \alpha \Rightarrow \frac{\theta_0^n - C^n}{\theta_0^n} = \alpha$$

$$\Rightarrow 1 - \alpha = \left(\frac{C}{\theta_0}\right)^n \text{ or } C = \theta_0 (1 - \alpha)^{1/n}$$

UMP test is then Reject H_0 if $X_{(n)} > \theta_0 (1 - \alpha)^{1/n}$.

So, we have UMP test for testing say H_0 theta less than or equal to theta_0 against say H_1 theta greater than theta_0. So, test is this UMP test will be reject H_0 if $X_{(n)}$ is greater than or equal to some constant C . This $X_{(n)}$ is having a continuous distribution. The density function of this will be $n y$ to the power $n - 1$ by θ_0 to the power n . So therefore, we do not have to consider the randomization we can consider rejection for greater than or equal to or greater than and acceptance; if $X_{(n)}$ is less than or equal to C where, C is determined by the size condition that is probability of $X_{(n)}$ greater than C when $\theta = \theta_0$ is equal to α .

Now, if I have this distribution this probability can be easily evaluated. This is turning out to be simply integral $n y$ to the power $n - 1$ by θ_0 to the power n dy from C to θ_0 . This is equal to α which is equivalent to $\theta_0^n - C^n$ to the power n divided by θ_0^n is equal to α . Now this can be further simplified we get $1 - \alpha$ is equal to C^n by θ_0^n to the power n or C is equal to $\theta_0 (1 - \alpha)^{1/n}$. So, UMP test is then reject H_0 if $X_{(n)}$ is greater than $\theta_0 (1 - \alpha)^{1/n}$. Let me also demonstrate the power function etcetera for this.

(Refer Slide Time: 07:53)

The power function of this test ϕ_1 is

$$\begin{aligned} \theta > \theta_0 \quad P_{\theta} (X_{(n)} > c) &= 1 - \left(\frac{c}{\theta}\right)^n & c = \theta_0 (1-\alpha)^{1/n} \\ &= 1 - \left(\frac{\theta_0}{\theta}\right)^n (1-\alpha) = \beta_{\phi}^*(\theta), \quad \theta > \theta_0. \end{aligned}$$

We propose another test in this case

$$\phi_2(x) = \begin{cases} 1 & X_{(n)} \geq \theta_0 \\ \alpha & X_{(n)} < \theta_0 \end{cases}$$

So $E_{\theta_0} \phi_2(x) = P_{\theta_0}(X_{(n)} \geq \theta_0) + \alpha P_{\theta_0}(X_{(n)} < \theta_0)$

$$= 0 + \alpha \cdot 1 = \alpha$$

So ϕ_2 also has size α .

when $\theta = \theta_0$
 $X_{(n)} \in [0, \theta_0]$

The power function of this test, let me call this test as phi 1 say. So, that is probability of X_n greater than C where C is actually $\theta_0 (1 - \alpha)^{1/n}$ and here θ will be greater than θ_0 . So, this is equal to $1 - \left(\frac{C}{\theta}\right)^n$ that is equal to $1 - \left(\frac{\theta_0}{\theta}\right)^n (1 - \alpha)$. Let us call it say $\beta_{\phi}^*(\theta)$. Here θ is greater than θ_0 .

Here I will also like to give one example see we have derived using the theorem which why given the last class that is for the families with the monotone likelihood ratio. UMP test can be has a particular form for the one sided testing problems. Now using that, we are able to exactly derive the form of the UMP test as this $X_n \geq \theta_0 (1 - \alpha)^{1/n}$. Let me call it phi 1 ok.

Now, we propose another test in this case, let me call it phi 2 and the test is 1 if X_n is greater than or equal to θ_0 and it is equal to α if X_n is less than θ_0 . Notice the difference here in the previous case, I was only rejecting or accepting; that means, it was a non randomized test, but this particular test is a randomized test because I am rejecting if X_n is greater than or equal to θ_0 .

But I am also rejecting with probability α if X_n is less than θ_0 . So, if I consider the expectation of phi 2 under θ_0 then it is equal to probability of $X_n \geq \theta_0$ when $\theta = \theta_0$ plus α times probability of $X_n < \theta_0$ when $\theta = \theta_0$. Now when

theta is equal to theta naught then X_n has the range 0 to theta naught when theta is equal to theta naught because the distribution of X_n is $n y$ to the power n minus 1 by theta to the power 1 from 0 to theta.

So, if I have assumed here that theta is equal to theta naught is the two parameter value which is actually required to calculate the size of the test. So, this probability will be 1 where as this property will be 0. So, you will get alpha. So, phi 2 also has size alpha ok.

(Refer Slide Time: 11:31)

Power of ϕ_2 , $\theta > \theta_0$

$$\beta_{\phi_2}^*(\theta) = \alpha P_{\theta}(X_n < \theta_0) + P_{\theta}(X_n \geq \theta_0)$$

$$= \alpha \left(\frac{\theta_0}{\theta}\right)^n + \frac{\theta^n - \theta_0^n}{\theta^n} = 1 - \left(\frac{\theta_0}{\theta}\right)^n (1-\alpha)$$

So $\beta_{\phi_1}^*(\theta) = \beta_{\phi_2}^*(\theta)$ for $\theta > \theta_0$

So ϕ_2 is also UMP

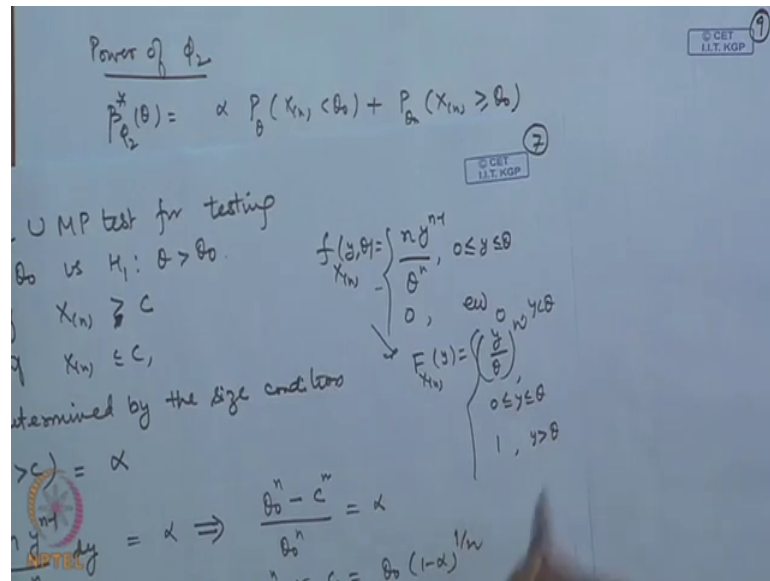

However of for $\theta < \theta_0$, $\beta_{\phi_1}^*(\theta) = 1 - \left(\frac{\theta_0}{\theta}\right)^n (1-\alpha)$

$$\leq 1 - (1-\alpha) = \alpha = \beta_{\phi_2}^*(\theta)$$

So ϕ_1 is have smaller size for $\theta < \theta_0$.

Let us now look at the power of phi 2 power of phi 2. So, power function of phi 2 is equal to alpha times probability theta X_n less than theta naught plus p theta naught X_n greater than or equal to theta naught. Now we have already considered the distribution of X_n which is of this form.

(Refer Slide Time: 12:07)

So, what is CDS here? That is y by θ to the power n for 0 less than or equal to y less than or equal to θ . It is 0 for y less than θ is equal to one for y greater than θ . Therefore, I can consider this thing here. I am considering the alternative set θ is greater than θ_0 . So, we are going only up to θ_0 . So, this probability will be θ_0^n by θ^n because this is y by θ to the power n that is the probability up to y .

So, this is θ_0^n by θ^n plus this is the probability from θ_0 to θ because in this particular case sorry this is only up to θ_0 here. So, this will be θ^n minus θ_0^n by θ^n . This will become 1 and this term I can combine. So, I can write it in a slightly modified fashion as θ_0^n by θ^n into 1 minus α . Now let us consider the power function of the ϕ_1 . The power function of ϕ_1 was 1 minus θ_0^n by θ^n into 1 minus α the power function of ϕ_2 is also same.

So, what we have proved that power functions of the two for θ greater than θ_0 are the same. So, ϕ_2 is also UMP. However, if we consider the power function that is for θ less than θ_0 $\beta \phi_1^*(\theta)$ that is 1 minus θ_0^n by θ^n into 1 minus α that is going to be less than or equal to. See θ_0^n minus θ^n is θ_0^n minus θ^n is greater than 0 ; if θ is less than θ_0 this is greater than 0 . So, if I take minus here this will be less.

So, this is less than or equal to one minus 1 minus alpha that is equal to alpha that is beta phi 2 star theta for theta less than theta naught. So, phi 1 is having smaller size for theta less than theta naught. So, I will consider here see, I have proposed I have derived one test phi 1 as the UMP test by the usual name and PSM theory. I proposed another test phi 2 I showed that the power function is the same. So, that is also UMP test. However, now what I am doing I am showing that the second test as uniformly the size is equal to alpha whereas the first test has it less than or equal to alpha.

(Refer Slide Time: 15:37)

Handwritten notes on a whiteboard:

$$= \alpha \left(\frac{\theta_0}{\theta}\right)^n + \frac{\theta^n - \theta_0^n}{\theta^n} = 1 - \left(\frac{\theta_0}{\theta}\right)^n (1-\alpha)$$

So $\beta_{\phi_1}^*(\theta) = \beta_{\phi_2}^*(\theta)$ for $\theta > \theta_0$

So ϕ_2 is also UMP

However if for $\theta < \theta_0$, $\beta_{\phi_1}^*(\theta) = 1 - \left(\frac{\theta_0}{\theta}\right)^n (1-\alpha)$

$$\leq 1 - (1-\alpha) = \alpha = \beta_{\phi_2}^*(\theta)$$

So ϕ_1 is have smaller size for $\theta < \theta_0$.

So ϕ_1 is better test than ϕ_2 .

NPTEL

So, I will consider phi 1 is better test than phi 2. In this particular case let me also demonstrate the reverse hypothesis that is the dual.

(Refer Slide Time: 15:55)

Let us also consider the dual problem in this case
 $H_0: \theta \geq \theta_0$ vs $H_1: \theta < \theta_0$.
 UMP test is given by Reject H_0 if $X_{(n)} < C$
 where $P_{\theta_0}(X_{(n)} < C) = \alpha$
 $\Rightarrow \left(\frac{C}{\theta_0}\right)^n = \alpha \Rightarrow C = \alpha^{1/n} \theta_0$.
 So the UMP test for K_0 vs K_1 is
 ϕ_3 : Reject H_0 if $X_{(n)} < \theta_0 \alpha^{1/n}$.
 Power fn. of ϕ_3
 $\beta_3^*(\theta) = P_{\theta}(X_{(n)} < C) = P_{\theta}(X_{(n)} < \theta_0 \alpha^{1/n})$
 $= \begin{cases} 1 & \text{if } \theta_0 \alpha^{1/n} > \theta \\ \left(\frac{\theta_0}{\theta}\right)^n \alpha & \text{if } \theta < \theta_0 \alpha^{1/n} \end{cases}$

Let us also consider the dual problem that is a H_1 called its K_0 against K_1 that is $\theta \geq \theta_0$ versus $\theta < \theta_0$. So, UMP test is given by reject H_0 if $X_{(n)}$ is less than C where probability of $X_{(n)}$ less than C under θ_0 should be equal to α . Now, once again this value is simply equal to when θ is equal to θ_0 , this value will be equal to C by θ_0 to the power n that is equal to α . That means, C is equal to $\alpha^{1/n} \theta_0$.

So, the test case test for K_0 versus K_1 is this is the UMP test reject; let me call it some name ϕ_3 reject K_0 if $X_{(n)}$ is less than $\theta_0 \alpha^{1/n}$. Compare it with the test that we derived for the dual problem that is H_0 versus H_1 . Here it was $X_{(n)}$ is greater than $\theta_0 (1 - \alpha)^{1/n}$ and here it is reject K_0 if $X_{(n)}$ is less than $\theta_0 \alpha^{1/n}$. Notice here that in both the cases, we have shifted little bit from θ_0 . So, note here this α is less than 1.

So, $\alpha^{1/n}$ is also less than 1. So, the cutoff point $\theta_0 \alpha^{1/n}$, but slightly less than that whereas for this one if you see the cutoff point is again a little less than θ_0 not exactly greater than or equal to θ_0 ok. We may also consider power for this part power function of ϕ_3 that is $\beta_3^*(\theta)$ that is equal to probability of $X_{(n)}$ less than C when θ is the parameter value, but θ is less than

θ_0 here that is equal to $P(\theta \leq \theta_0 | \alpha^{1/n})$.

Now, the range of X_n is from 0 to θ_0 and this θ_0 is less than θ . So, there can be two cases here. This $\alpha^{1/n}$ because $\theta_0 < \alpha^{1/n}$ to the power $1/n$. This value is actually less than θ_0 . So, this could be here or this could be here. So, this is equal to 1 if $\theta_0 < \alpha^{1/n}$ is greater than θ . Otherwise this value is equal to $\theta_0 / \theta^{1/n}$ if $\theta_0 < \alpha^{1/n}$.

You can compare the power functions in the two cases here I have derived the power function for the other part also. The power function for θ_0 was given by $1 - (\theta_0 / \theta)^{n-1} \alpha^{1/n}$ here and here you can see this value is $\theta_0 / \theta^{1/n}$ here. Now, these two tests; these two tests can be combined also. If I can combine I can write in this particular case for if I am considering θ_0 is equal to θ_0 against θ_0 equal to θ_0 , then for θ_0 greater than or equal to θ_0 the rejection region is given by X_n greater than something and that something we have determined actually.

So, if we distribute that probability we can slightly modify this statement here and similarly for $\theta_0 < \theta$, the rejection region is X_n less than something. So, X_n greater than something X_n less than something I can combine these two statements to get a UMP test here for the two sided problem also. Let me continue with some further applications here for the UMP test here.

So, note here either we have the distributions in the exponential family. Usually here we are considered one parameter exponential family because so far whatever testing problems we have discussed, we have considered only one parameter. When we have more than one parameter for example, in the normal distribution we may consider normal μ σ^2 or in exponential distribution we may consider location and scale both. In those cases, we will see that in place of the uniformly most powerful test you have to restrict attention to only unbiased test and then we will be able to get the UMP unbiased test.

So, those things we will be considered in the following lecture here my intention is to show either we considered the distributions in the exponential family or we consider the

distributions with the monotone likelihood ratio. So, therefore, we can be able to derive the UMP tests.

(Refer Slide Time: 22:37)

Example: $X \sim f(x, \theta) = \begin{cases} \frac{1}{2}(1+\theta x), & -1 < x < 1, -1 \leq \theta \leq 1 \\ 0, & \text{ew} \end{cases}$

$\theta_1 > \theta_2$

$$r(x) = \frac{f(x, \theta_1)}{f(x, \theta_2)} = \frac{1+\theta_1 x}{1+\theta_2 x}, \quad r'(x) = \frac{\theta_1(1+\theta_2 x) - \theta_2(1+\theta_1 x)}{(1+\theta_2 x)^2}$$

So $r(x)$ is \uparrow fn. of x . $= \frac{\theta_1 - \theta_2}{(1+\theta_2 x)^2} > 0$

So the family of densities has MLR in (θ, x)

$H_0: \theta \geq 0$ UMP test, Reject H_0 if $X < c$

$H_1: \theta < 0$

$$P(X < c) = \alpha$$

$$\Rightarrow \int_{-1}^c \frac{1}{2} dx = \frac{c+1}{2} = \alpha \Rightarrow c = 2\alpha - 1$$

So test is Reject H_0 if $X < 2\alpha - 1$.

Let me take slightly different example which is naught a very conventional one half 1 plus theta x minus 1 less than x less than 1 minus 1 less than or equal to theta less than or equal to 1 and it is of course, 0 elsewhere. Now if you look at this certainly, it is not in the form of an exponential family. So, what we can do? We can consider whether the monotone likelihood ratio is there or not. So, let us look at that. If I consider the ratio of the let me consider say one observation here ok, in place of n I am considering for the convenience one observation $f(x, \theta_1)$ divided by $f(x, \theta_2)$. Let us take say theta 1 is greater than or greater than theta 2.

So, this ratio will become 1 plus theta 1 x divided by 1 plus theta 2 x. So, whether this is increasing or decreasing, it will depend upon theta 1 greater than theta 2. Let us look at for example, what is derivative of this. So, derivative will give you theta 1 into 1 plus theta 2 x minus theta 2 into 1 plus theta 1 x divided by 1 plus theta 2 x whole square. So, this is equal to theta 1 minus theta 2 divided by 1 plus theta 2 x square and since theta 1 is greater than theta 2; this is positive. So, what we are concluding is that $r(x)$ is increasing function of x . So, this distributions so, the family of densities that we have considered here has monotone likelihood ratio in theta and x . So, now, it is nice that we can actually

derive the UMP test. Suppose I consider one sided testing problem theta greater than or equal to 0 against say theta less than 0.

So, UMP test will be reject H naught if X is less than C and C is determined from the size condition; so, probability of X less than C when theta is equal to 0, this should be equal to alpha. Now when theta is equal to 0, the density will become half that is simply the uniform distribution. So, this is actually half from minus 1 to C that is equal to C plus 1 by 2 that is equal to alpha; that means, C will be equal to twice alpha minus 1. So, test is reject H naught if X is less than twice alpha minus 1. So, we are able to get a exact form of the testing procedure here; this is the UMP test in this particular problem.

(Refer Slide Time: 26:01)

Power fn. of this test

$$P_{\theta}(X < 2\alpha - 1) = \int_{-1}^{2\alpha - 1} \frac{1}{2}(1 + \theta x) dx = \alpha \left\{ \begin{array}{l} 1 + \theta(\alpha - 1) \\ \alpha \quad \theta = 0 \\ < \alpha \quad \theta > 0 \\ > \alpha \quad \theta < 0 \end{array} \right.$$

Example: Let X_1, \dots, X_n be a random sample from exponential distⁿ $f(x, \sigma) = \frac{1}{\sigma} e^{-x/\sigma}, x > 0, \sigma > 0$

$H_0: \lambda \leq \lambda_1$ or $\lambda \geq \lambda_2$

$H_1: \lambda_1 < \lambda < \lambda_2$ ($\lambda_1 < \lambda_2$)

UMP test is Reject H_0 if $C_1 < \sum X_i < C_2$

$P_j(C_1 < \sum X_i < C_2) = \alpha, j=1, 2.$

Additional notes on slide: $Q(\sigma) = -\frac{1}{\sigma} \uparrow$ in σ , $T(x) = x$, $\frac{1}{\sigma^n} e^{-\frac{\sum x_i}{\sigma}}$, $\pi(\lambda) = \sum x_i$

Let us also consider power function that is probability of X less than 2 alpha minus 1 for theta when theta is less than 0. So, in this case, the density is half 1 plus theta x. So, we integrate from minus 1 to twice alpha minus 1.

So, after simplification this value turns out to be simply alpha into 1 plus theta into alpha minus 1. So, actually you can see at theta is equal to 0, this is exactly equal to alpha for theta greater than 0, it will be less than alpha. So, this is equal to alpha or theta is equal to 0. It is less than alpha. If I take theta to be greater than 0 if theta is greater than 0 alpha minus 1 is negative. Therefore, this value will become less than alpha and it is greater than alpha for theta less than 0. So, the result which actually I stated when we were

giving the result about the UMP test is exactly shown to be satisfied here. Let me read out from the statement that we gave that day.

So, if the distribution of X has $f(x; \theta)$ has MLR in θ $T(x)$ and the most powerful test is of this form, then what we said here that for the values of θ which are bigger that is it will be greater than or equal to power and for lower side, it is actually increasing function; $\phi(\beta; \theta)$ is a increasing function of θ . I think I yeah this is β θ is strictly increasing function of θ for which is this is true.

So, this is followed here. Let us consider here exponential distribution let X_1, X_2, \dots, X_n be a random sample from exponential distribution. So, we are considering simply one parameter exponential distribution with scale parameter setup. Now this is simply one parameter exponential family. If I consider $Q(\sigma)$ that is equal to $-\frac{1}{\sigma}$ by σ this is increasing in σ and $T(x)$ here is x . So, this is one parameter exponential family with the setup that we have stated in the theorem. So, even for the two sided null hypothesis, we will be able to derive a UMP test.

So, if I consider say $H_0: \lambda \leq \lambda_1$ or $\lambda \geq \lambda_2$ against $\lambda_1 < \lambda < \lambda_2$. Here $\lambda_1 < \lambda_2$ UMP test is reject H_0 . If C_1 is less than now if you see here when I write down the distribution of n of these observations, then it will become $\frac{1}{\sigma^n} e^{-\frac{x_i}{\sigma}}$ to the power n $e^{-\frac{x_i}{\sigma}}$. So, $T(x)$ then in that case will become equal to $\sum x_i$. So, we will get $\sum x_i < C_2$ where probability of $C_1 < \sum x_i < C_2$ when λ_1 or λ_2 is true this is equal to α that is j is equal to 1, 2.

(Refer Slide Time: 30:39)

$2\lambda \sum x_i \sim \chi^2_{2n}$
 $P_{\lambda_j}(2\lambda_j C_1 < W < 2\lambda_j C_2) = \alpha, j=1,2,\dots (*)$
 $W \sim \chi^2_{2n}$
 C_1, C_2 can be determined from equations (*) using tables of χ^2 distⁿ for given $\lambda_1, \lambda_2, n, \alpha$.
 $\lambda_1=1, \lambda_2=2, \alpha=0.1, n=5$
 We may then determine C_1, C_2 by interpolating from tables of χ^2_{10} distⁿ.

Now, we can see that lambda times sigma x i and if I take two times that it will have chi square distribution on two one degrees of freedom. So, we can write down this conditions probability of twice lambda C 1 less than so, this is W variable less than twice lambda. So, let me put j here W, this is equal to alpha for j is equal to 1, 2. This is when lambda j is true where w follows chi square 2. So, let me call this equation star. So, C 1 and C 2 can be determined from sorry this is C 2 here. C 1 and C 2 can be determined from equations star using tables of chi square distribution for given lambda 1 lambda 2 n and alpha.

So, for example, in a given problem you may have lambda 1 is equal to say one lambda 2 is equal to say 2 alpha is equal to say 0.1, then you and say n is equal to phi, then you need to look at that tables of chi square ten distribution; chi square on ten degrees of freedom and you can determine this conditions here. We may then determine C 1 and C 2 by interpolating from tables of chi square distribution on ten degrees of freedom. Let me make mention about the location scale distributions. Under certain conditions, this location is skill distributions also have the monotone likelihood ratio property. So, let me give that thing.

(Refer Slide Time: 33:13)

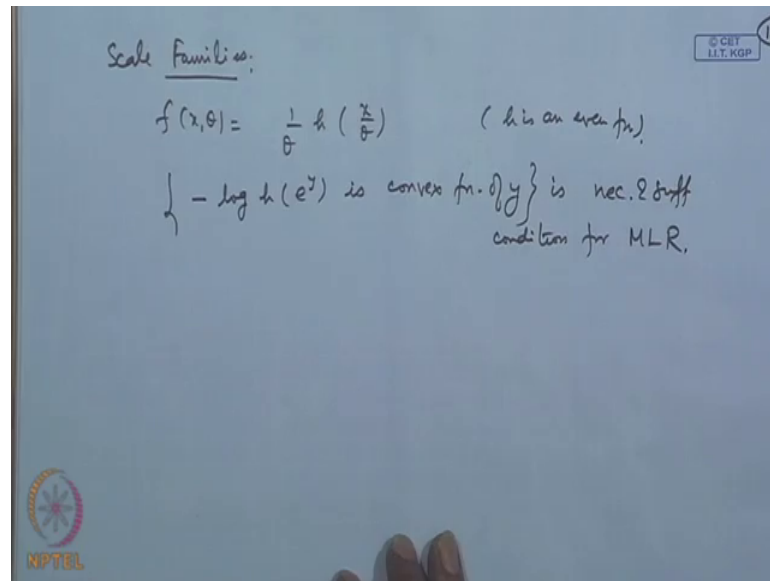

Location Families.
 $f(x, \theta) = g(x - \theta) > 0$ (let $x \in \mathbb{R}$)
 Then a necessary and sufficient condition for $f(x, \theta)$ to have
 MLR is that $-\log g$ is ~~convex~~ convex.
 Pf: $\frac{g(x - \theta_1)}{g(x - \theta_2)} \leq \frac{g(x^* - \theta_1)}{g(x^* - \theta_2)}$, $x < x^*$, $\theta_1 > \theta_2$
 $\Rightarrow \log g(x^* - \theta_2) + \log g(x - \theta_1) \leq \log g(x - \theta_1) + \log g(x^* - \theta_2)$
 $x - \theta_1 = t(x - \theta_2) + (1-t)(x^* - \theta_1)$
 $x^* - \theta_2 = (1-t)(x - \theta_2) + t(x^* - \theta_1)$
 $t = \frac{x^* - x}{x^* - x + \theta_2 - \theta_1}$ (if $-\log g$ is convex)

So, let us consider say location families; that means, my $f(x, \theta)$ is of the form $g(x - \theta)$ and of course, let us take x belonging to \mathbb{R} that is this is positive for all x ok. Then a necessary and sufficient condition for $f(x, \theta)$ to have monotone likelihood ratio is that minus log of g is concave is convex sorry. This can be actually proved here; if I consider $g(x - \theta_1) / g(x - \theta_2)$ where θ_1 is greater than θ_2 , then we have to show that this is increasing function of x .

That means, if I consider x^* for $x < x^*$. This is what we should show for monotone likelihood ratio that is $g(x - \theta_1) / g(x - \theta_2)$ to be an increasing function. So, if I take logarithms this is reducing to $\log g(x^* - \theta_2) + \log g(x - \theta_1) \leq \log g(x - \theta_1) + \log g(x^* - \theta_2)$.

Now, we can actually interpret something like this $x - \theta_1$, we can write as some t times $x - \theta_1 - \theta_2$ plus $(1-t)$ times $x^* - \theta_1$ and we may also write $x^* - \theta_2$ is equal to $(1-t)$ times $x - \theta_2$ plus t times $x^* - \theta_1$ where t I am choosing to be $(x^* - x) / (x^* - x + \theta_2 - \theta_1)$. Then if we do that then if minus log g is convex then this will be true and converse is also true that is it is necessary and sufficient.

(Refer Slide Time: 36:41)

I will just mention about the scale families also. For a scale families, we can consider the shifting two like if I consider $f(x, \theta) = \frac{1}{\theta} h\left(\frac{x}{\theta}\right)$ where h is an even function. In that case a necessary and sufficient condition will be that $-\log h(e^y)$ is convex function of y . This is a necessary and sufficient condition for monotone likelihood ratio. Now we will consider the application of this Neymann Pearson theory to the cases when the UMP tests do not exist. So, we will consider some further criteria and that I will be developing in the next lecture.
