Lecture - 56
Likelihood Ratio Tests - VI

Let me again repeat the model. We are considering the two sample problem I had taken variances to be common.

(Refer Slide Time: 00:25)

Now, in general situations, we do not know whether the variances will be common or not. So, in order to test about the comparison of the means we firstly need to check whether the variances are the same or not. So, let us consider the testing for the variances.

(Refer Slide Time: 00:51)

In two sample problem for testing about means we have assumed the equality of variances ($\sigma_1^2 = \sigma_2^2$). However, in practice we do not know this. So it is advisable to carry out a test for equality of variances.

Let $X = (X_1, \dots, X_m)$ is a random sample from $N(\mu_1, \sigma_1^2)$
& $Y = (Y_1, \dots, Y_n)$ is a random sample from $N(\mu_2, \sigma_2^2)$.

$H_1: \frac{\sigma_2^2}{\sigma_1^2} \leq \tau_0$
 $H_2: \frac{\sigma_2^2}{\sigma_1^2} > \tau_0$

$\tau \leq \tau_0$
 $\tau > \tau_0$

NPTL

In two sample problems for testing about means, we have assumed the equality of variances. That is sigma 1 square is equal to sigma 2 square; however, in practice we do not know this.

So, it is advisable to carry out a test for equality of variances. So, I will provide this here. We have the model that is X_1, X_2, \dots, X_m that is X is a random sample from normal μ_1 sigma 1 square. And Y_1, Y_2, \dots, Y_n is a random sample from normal μ_2 sigma 2 square. For comparison of the variances; I consider the hypothesis of the nature say H_1 sigma 2 square by sigma 1 square less than or equal to some number say tau naught; tau let us say and H_2 sigma 2 square by sigma 1 square greater than tau naught; that is the alternative hypothesis.

Sigma 2 square by sigma 1 square is greater than tau say. Let me call this as tau and this as tau naught value this is tau. So, we want to check whether tau is less than or equal to tau naught and our tau is greater than tau naught; that means, my likelihood ratio then I am considering I will represent in the terms of this ratio tau.

(Refer Slide Time: 03:37)

Consider the likelihood function

$$\theta = (\mu_1, \mu_2, \sigma_1^2, \sigma_2^2)$$

$$\Omega = \left\{ \theta : \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1,2 \right\}$$

$$\Omega_H = \left\{ \theta : \mu_i \in \mathbb{R}, \sigma_2^2 \leq \tau_0 \sigma_1^2, \sigma_i^2 > 0 \right\}$$

$$L(\theta; \mathbf{x}, \mathbf{y}) = \frac{1}{(2\pi\sigma_1^2)^{m/2}} \cdot \frac{1}{(2\pi\sigma_2^2)^{n/2}} e^{-\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\sigma_2^2}}$$

$$l(\theta) = \log L = -\frac{m+n}{2} \log 2\pi - \frac{m}{2} \log \sigma_1^2 - \frac{n}{2} \log \sigma_2^2 - \frac{1}{2\sigma_1^2} \sum(x_i - \mu_1)^2 - \frac{1}{2\sigma_2^2} \sum(y_j - \mu_2)^2$$

$$\frac{\partial l}{\partial \mu_1} = \frac{m(\bar{x} - \mu_1)}{\sigma_1^2} < 0 \text{ for } \mu_1 > \bar{x} > 0 \text{ for } \mu_1 < \bar{x} \left. \vphantom{\frac{\partial l}{\partial \mu_1}} \right\} \text{ So } \hat{\mu}_{1\Omega} = \bar{x}$$

So, consider the likelihood function. Now note here my parameter is now four dimension. Four dimensional parameter set is there mu 1, mu 2, sigma 1 square, sigma 2 square. The null hypothesis parameter set is this mu i's are real and sigma i square is positive for i is equal to 1, 2 . And in the null hypothesis parameter set we are having the restriction that sigma 2 square is less than or equal to tau naught sigma 1 square.

And of course, both are positive. So, this additional restriction has come here. So, the likelihood function, now l theta x, y that is equal to 1 by 2 pi sigma 1 square to the power m by 2 1 by 2 pi sigma 2 square to the power n by 2 e to the power minus sigma x i minus mu 1 square by 2 sigma 1 square minus sigma y j minus mu 2 square by 2 sigma 2 square. So, we consider the log likelihood, that is equal to minus m plus n by 2 log of 2 pi minus m by 2 log of sigma 1 square minus n by 2 log of sigma 2 square minus 1 by 2 sigma 1 square sigma x i minus mu 1 square minus 1 by sigma 2 square sigma y j minus mu 2 square.

So, this is a full set up with four parameters in the two normal populations and they are independent therefore, the solution is straightforward here that is if I considered del l by del mu 1 that will give me m x bar minus mu 1 by sigma 1 square less than 0 for mu 1 greater than x bar greater than 0 for mu 1 less than x bar. So, mu 1 omega hat that will be equal to x bar.

(Refer Slide Time: 06:39)

$(2\pi\sigma_1^2)^{m/2} (2\pi\sigma_2^2)^{n/2}$

$\frac{\partial \ell}{\partial \mu_2} = \frac{n(\bar{y} - \mu_2)}{\sigma_2^2} < 0 \text{ for } \mu_2 > \bar{y}$
 $> 0 \text{ for } \mu_2 < \bar{y}$

$\} \text{ So } \hat{\mu}_{1,2} = \bar{y}$

$\frac{\partial \ell}{\partial \sigma_1^2} = -\frac{m}{2\sigma_1^2} + \frac{1}{2\sigma_1^4} \sum (x_i - \mu_1)^2 = \frac{m}{2\sigma_1^4} \left[\frac{1}{m} \sum (x_i - \mu_1)^2 - \sigma_1^2 \right]$

$> 0 \text{ for } \sigma_1^2 < \frac{1}{m} \sum (x_i - \mu_1)^2$
 $< 0 \text{ for } \sigma_1^2 > \frac{1}{m} \sum (x_i - \mu_1)^2$

$\text{So } \hat{\sigma}_{1n}^2 = \frac{1}{m} \sum (x_i - \bar{x})^2$

$\text{Similarly } \hat{\sigma}_{2n}^2 = \frac{1}{n} \sum (y_j - \bar{y})^2$

Similarly, if I consider say del l by del mu 2 then that will be n y bar minus mu 2 divided by sigma 2 square. Once again it is less than 0 for mu 2 greater than y bar less than and it is greater than 0 for mu 2 less than y bar.

So, mu 2 hat omega that is equal to y bar. Let us also consider maximization with respect to sigma 1 square and sigma 2 square. So, let us look at this term del l by del sigma 1 square that is equal to minus m by 2 sigma 1 square plus 1 by 2 sigma 1 to the power 4 sigma x i minus mu 1 square that is equal to m by 2 sigma 1 to the power 4 1 by m sigma x i minus mu 1 square minus sigma 1 square. So, this is greater than 0 for sigma 1 square less than 1 by m sigma x i minus mu 1 square it is less than 0 for sigma 1 square greater than 1 by m sigma x i minus mu 1 square.

So, the maximization with respect to sigma 1 square is then occurring at 1 by m sigma x i minus mu 1 square. Now mu 1 is maximized at x bar. So, it is 1 by m sigma x i minus x bar whole square. Now similarly if I look at the maximization with respect to sigma 2 square; that will become 1 by n sigma y j minus y bar square. Now these values I substitute in likelihood function. In this likelihood function if I substitute the maximizing values I get.

(Refer Slide Time: 08:59)

$$\frac{\partial L}{\partial \mu_1} = \frac{n(\bar{y} - \mu_1)}{\sigma_1^2} < 0 \text{ for } \mu_1 > \bar{y}$$

$$> 0 \text{ for } \mu_1 < \bar{y}$$

$$\left. \begin{array}{l} < 0 \text{ for } \mu_1 > \bar{y} \\ > 0 \text{ for } \mu_1 < \bar{y} \end{array} \right\} \text{ So } \hat{\mu}_{2\Omega} = \bar{y}$$

$$\frac{\partial L}{\partial \sigma_1^2} = -\frac{m}{2\sigma_1^2} + \frac{1}{2\sigma_1^4} \sum (x_i - \mu_1)^2 = \frac{m}{2\sigma_1^4} \left[\frac{1}{m} \sum (x_i - \mu_1)^2 - \sigma_1^2 \right]$$

$$> 0 \text{ for } \sigma_1^2 < \frac{1}{m} \sum (x_i - \mu_1)^2$$

$$< 0 \text{ for } \sigma_1^2 > \frac{1}{m} \sum (x_i - \mu_1)^2$$

$$\hat{\sigma}_{1\Omega}^2 = \frac{1}{m} \sum (x_i - \bar{x})^2$$

Similarly $\hat{\sigma}_{2\Omega}^2 = \frac{1}{n} \sum (y_j - \bar{y})^2$

$$\text{So } L(\Omega) = \frac{1}{(2\pi)^{(m+n)/2} (\hat{\sigma}_{1\Omega}^2)^{m/2} (\hat{\sigma}_{2\Omega}^2)^{n/2}} e^{-\frac{m+n}{2}}$$

So, $\hat{\Omega}$ that becomes equal to 1 by 2π to the power $m+n$ by 2 $\hat{\sigma}_{1\Omega}^2$ to the power m by 2 $\hat{\sigma}_{2\Omega}^2$ to the power n by 2 e to the power minus $m+n$ by 2 .

(Refer Slide Time: 09:33)

Under Ω_H : Since maximization of L w.r.t μ_1 & μ_2 does not depend on σ_1^2 & σ_2^2 , we get $\hat{\mu}_{1\Omega_H} = \bar{x}$, $\hat{\mu}_{2\Omega_H} = \bar{y}$.
 Maximization w.r.t σ_1^2 & σ_2^2 , we first fix σ_1^2 .
 Then
$$\frac{\partial L}{\partial \sigma_2^2} = -\frac{n}{2\sigma_2^2} + \frac{1}{2\sigma_2^4} \sum (y_j - \mu_2)^2$$

$$= \frac{n}{2\sigma_2^4} \left[\frac{1}{n} \sum (y_j - \mu_2)^2 - \sigma_2^2 \right]$$

$$> 0 \iff \text{for } \sigma_2^2 < \frac{1}{n} \sum (y_j - \mu_2)^2$$

$$< 0 \iff \text{for } \sigma_2^2 > \dots$$

Under Ω_H . Now let us consider under Ω_H we are having now if you look at the maximization with respect to μ_1 and μ_2 there is no dependence on σ_1^2 and σ_2^2 . So, it will not change. Since maximization of L with respect to μ_1 and μ_2 does not depend on σ_1^2 and σ_2^2 , we get $\hat{\Omega}$

sorry μ_1 hat ω_H as \bar{x} μ_2 ω_H hat is \bar{y} ; however, if I consider for σ_1^2 and σ_2^2 , then here we are having the region σ_2^2 is less than or equal to $\tau_0 \sigma_1^2$ in the alternative hypothesis set; that is $\sigma_2^2 \leq \tau_0 \sigma_1^2$.

So, this will play a role here. So, for maximization with respect to σ_1^2 and σ_2^2 , we first say fix σ_1^2 say ok. Then we are saying σ_2^2 is less than or equal to. So, if I consider the derivative of the likelihood function with respect to σ_2^2 , I get $-\frac{n}{2\sigma_2^4} (\frac{1}{n} \sum (y_j - \mu_2)^2 - \sigma_2^2)$. That I can write as $-\frac{n}{2\sigma_2^4} (\frac{1}{n} \sum (y_j - \bar{y})^2 - \sigma_2^2)$. So, this is less than 0; it is greater than 0 for $\sigma_2^2 < \frac{1}{n} \sum (y_j - \bar{y})^2$ and it is less than 0 for $\sigma_2^2 > \frac{1}{n} \sum (y_j - \bar{y})^2$.

.So, the behavior of the likelihood function with respect to σ_2^2 .

(Refer Slide Time: 12:23)

$$= \frac{n}{2\sigma_2^4} \left[\frac{1}{n} \sum (y_j - \mu_2)^2 - \sigma_2^2 \right]$$

$$> 0 \iff \text{for } \sigma_2^2 < \frac{1}{n} \sum (y_j - \mu_2)^2 \quad \frac{1}{n} \sum (y_j - \bar{y})^2 \text{ as } \hat{\mu}_2 = \bar{y}$$

$$< 0 \quad \text{for } \sigma_2^2 > \dots$$

So if $\frac{1}{n} \sum (y_j - \bar{y})^2 < \sigma_1^2 \tau_0$
 then $\hat{\sigma}_2^2 = \frac{1}{n} \sum (y_j - \bar{y})^2$
 Otherwise, $\hat{\sigma}_2^2 = \sigma_1^2 \tau_0$
 So $\hat{\sigma}_2^2 = \min \left(\tau_0 \sigma_1^2, \frac{1}{n} \sum (y_j - \bar{y})^2 \right)$

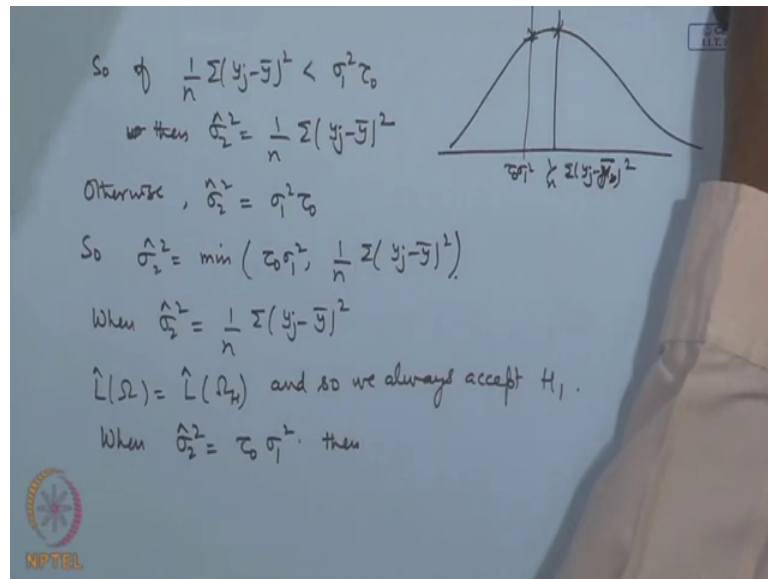

The graph shows a bell-shaped curve representing the likelihood function. A vertical line is drawn at the peak of the curve, which is labeled $\frac{1}{n} \sum (y_j - \bar{y})^2$. Another vertical line is drawn to the left of the peak, labeled $\tau_0 \sigma_1^2$. The peak of the curve is to the right of the $\tau_0 \sigma_1^2$ line, indicating that the maximum likelihood estimate is the sample variance.

That means if I consider the plotting of the likelihood function with respect to σ_2^2 . Then at the point $\frac{1}{n} \sum (y_j - \bar{y})^2$ this is the maximization point. Now if this quantity $\frac{1}{n} \sum (y_j - \bar{y})^2$ is occurring at \bar{y}^2 because I have substituted μ_2 hat is equal to \bar{y} . So, here I can put μ_2 as $\frac{1}{n} \sum (y_j - \bar{y})^2$ as μ_2 hat ω_H that is equal to \bar{y} . So, if $\frac{1}{n} \sum (y_j - \bar{y})^2 < \tau_0 \sigma_1^2$

$\sigma^2 \sum (y_j - \bar{y})^2 < \tau_0^2 \sigma^2$ then $\hat{\sigma}^2$ that is equal to $\frac{1}{n} \sum (y_j - \bar{y})^2$.

Otherwise suppose $\tau_0^2 \sigma^2$ is here. If that is happening, then $\hat{\sigma}^2$ this maximization is then occurring at this point that is equal to $\tau_0^2 \sigma^2$. So, we are saying $\hat{\sigma}^2$ is equal to actually minimum of $\tau_0^2 \sigma^2$ and $\frac{1}{n} \sum (y_j - \bar{y})^2$.

(Refer Slide Time: 14:09)

So, when $\hat{\sigma}^2$ that is equal to $\frac{1}{n} \sum (y_j - \bar{y})^2$. I will get $\hat{L}(\Omega)$ and $\hat{L}(\Omega_H)$ same. And so, we always accept H_1 . Because the likelihood ratio is supposed to be between 0 and 1. So, if it is equal to 1 we always accept H_1 . Now the other case when $\hat{\sigma}^2$ is equal to $\tau_0^2 \sigma^2$ square.

In that case with respect to σ^2 when I consider the likelihood function let us look at the term once again.

(Refer Slide Time: 15:07)

Handwritten notes on a whiteboard:

$$l(\mu) = \log L = -\frac{m}{2} \log \sigma_1^2 - \frac{1}{2\sigma_1^2} \sum (x_i - \mu)^2 - \frac{1}{2\sigma_2^2} \sum (y_j - \mu)^2$$

$$\frac{d}{d\mu} l(\mu) = \frac{m(\bar{x} - \mu)}{\sigma_1^2} < 0 \text{ for } \mu > \bar{x}$$

$$\frac{d}{d\mu} l(\mu) = \frac{m(\bar{x} - \mu)}{\sigma_1^2} > 0 \text{ for } \mu < \bar{x}$$

So $\hat{\mu}_{1,2} = \bar{x}$.

When $\hat{\sigma}_2^2 = \tau_0 \sigma_1^2$, then

$$l(\tau_0) = \left(\right) - \frac{m}{2} \log \sigma_1^2 - \frac{n}{2} \log \tau_0 \sigma_1^2 - \frac{1}{2\sigma_1^2} \left[\sum (x_i - \mu)^2 + \frac{1}{\tau_0} \sum (y_j - \mu)^2 \right]$$

$$\left(\right) - \frac{m}{2} \log \sigma_1^2 - \frac{n}{2} \log \tau_0 \sigma_1^2 - \frac{1}{2\sigma_1^2} \left[\sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right]$$

Let me look at this term [laughter]; small l. So, small l theta that is equal to now this will become. So, these terms will be there minus m by 2 log of sigma 1 square minus n by 2 log of tau naught sigma 1 square minus 1 by 2 sigma 1 square sigma x i minus mu 1 square plus 1 by tau naught sigma y j minus mu 2 square. Now we have already got the maximizing values of this. So, I will put it here x bar here. So, this term then I get minus m by 2 log of sigma 1 square minus n by 2 log of tau naught sigma 1 square minus 1 by 2 sigma 1 square sigma x i minus x bar square plus 1 by tau naught sigma y j minus y bar whole square ok.

That means, the maximization problem with respect to sigma 1 square now it has been reduced to maximization of this term. So, let us consider that now.

(Refer Slide Time: 16:27)

So now

$$\frac{\partial L}{\partial \sigma_1^2} = -\frac{m}{2\sigma_1^2} - \frac{n}{2\sigma_1^2} + \frac{1}{2\sigma_1^4} \left[\sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right]$$

$$= -\frac{m+n}{2\sigma_1^4} \left[\frac{1}{m+n} \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 - \sigma_1^2 \right]$$

So Analyzing as before, we get

$$\hat{\sigma}_{1,H}^2 = \frac{1}{m+n} \left[\sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right]$$

$$\tau \hat{\sigma}_{2,H}^2 = \frac{\tau_0}{m+n} \left[\sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right]$$

So now del l by del sigma 1 square that will give me let us look at this thing. So, minus m by 2 sigma 1 square minus n by 2 sigma 1 square. And this term will not play a role plus 1 by 2 sigma 1 to the power 4 sigma x i minus x bar square plus 1 by tau naught sigma y j minus y bar square. So, that I can write as minus m plus n by twice sigma 1 to the power 4 1 by m plus n sigma x i minus x bar square plus 1 by tau naught sigma y j minus y bar square minus sigma 1 square.

So, if we carry out the analysis as we have been doing. So, analyzing as before we get here; sigma 1 omega H hat square that is equal to 1 by m plus n sigma x i minus x bar square plus 1 by tau naught sigma y j minus y bar square. And sigma 2 omega H hat square that is tau naught times this. So, it becomes tau naught divided by m plus n and the same term here x i minus x bar square plus 1 by tau naught sigma y j minus y bar square.

(Refer Slide Time: 19:03)

Then $\hat{L}(\Omega_H) = \frac{1}{(2\pi)^{\frac{m+n}{2}} \tau_0^{\frac{m+n}{2}} \left(\frac{\hat{\sigma}_1^2}{\hat{\sigma}_2^2}\right)^{\frac{m+n}{2}}} e^{-\frac{m+n}{2}}$

So the LRT test is Reject H_1 if

$$\lambda(x,y) = \frac{\hat{L}(\Omega_H)}{\hat{L}(\Omega)} < c$$

$$\Leftrightarrow \frac{\left(\frac{\hat{\sigma}_1^2}{\hat{\sigma}_2^2}\right)^{\frac{m+n}{2}} \left(\frac{\hat{\sigma}_2^2}{\hat{\sigma}_1^2}\right)^{\frac{m+n}{2}}}{\tau_0^{\frac{m+n}{2}} \left(\frac{\hat{\sigma}_1^2}{\hat{\sigma}_2^2}\right)^{\frac{m+n}{2}}} < c \Leftrightarrow \frac{\left\{\sum(x_i - \bar{x})^2\right\}^{\frac{m}{2}} \left\{\sum(y_j - \bar{y})^2\right\}^{\frac{n}{2}}}{\left\{\sum(x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum(y_j - \bar{y})^2\right\}^{\frac{m+n}{2}}} < c$$

$$\Leftrightarrow \frac{\left\{\sum(x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum(y_j - \bar{y})^2\right\}^{\frac{m+n}{2}}}{\left\{\sum(x_i - \bar{x})^2\right\}^{\frac{m}{2}} \left\{\sum(y_j - \bar{y})^2\right\}^{\frac{n}{2}}} > c_2$$

So, these values then I substitute in the likelihood function to get L hat omega H as 1 by 2 pi to the power m plus n by 2.

And then I will be getting. So, if you look at the original form of the likelihood function here you see here sigma 2 square I am saying sigma 1 square tau naught. So, this term and this term will get combined and tau naughts power will come here. So, I will get tau naught to the power n by 2 and then these 2 will get combined. So, I will get sigma 1 omega H hat square to the power m plus n by 2 in the denominator. And then in the exponent part here also what is happening sigma 2 square is sigma 1 square tau naught. So, this term I get outside then I get sigma x i minus x bar whole square plus 1 by tau naught sigma y j minus y bar whole square and 1 by tau naught is coming. So, this term will get simply cancelled out and I will get e to the power minus m plus n by 2.

So, let us look at the expressions that we derived in the page 11 I have written the expression for this value here e on page 9 yeah L hat omega. So, you look at this L hat omega is this. So, this coefficient is common in L hat omega H and L hat omega. And here I am getting sigma 1 omega hat square and sigma 2 hat omega square and here it is same term sigma 1 hat omega H square to the power m plus n by 2; this e to the power minus m plus n by 2 will also get cancelled out when I take the ratio.

So, the likelihood ratio test then will give me. So, the likelihood ratio test is reject H 1 if lambda x y that is equal to L hat omega H by L hat omega less than c. This is equivalent

to sigma one hat omega square to the power m by 2 sigma 2 omega hat square to the power n by 2 divided by sigma 1 hat omega square to the power m plus n by 2 and tau naught to the power n by 2 less than say c. I have cancelled out the constant terms from here.

Once again this does not play any role here. And these terms then I simplify what I do. Firstly, because in the sigma 1 omega hat, H; this is H here. In this term I am getting both sum of squares. Here only sum of squares of the first term is coming. So, this is equivalent to I can say sigma x i minus x bar square to the power say m by 2 sigma y j minus y bar square to the power say n by 2 divided by sigma x i minus x bar square plus 1 by tau naught sigma y j minus y bar square to the power m plus n by 2 greater than sorry less than say c some. Coefficient will get cancelled out because for example, 1 by m was here 1 by n is here. So, let me call it c 1 here.

So, this is then equivalent to I take the reciprocal. I can express it as sigma x i minus x bar square plus 1 by tau naught sigma y j minus y bar square to the power m plus n by 2 divided by sigma x i minus x bar square to the power m by 2 sigma y j minus y bar square to the power n by 2 greater than say c 2.

(Refer Slide Time: 23:53)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a definition: $\lambda(\xi) = \frac{\hat{L}(\Omega_0)}{\hat{L}(\Omega)} < c$. Below this, several equivalent forms are shown using double-headed arrows. The first form is $\frac{(\hat{\sigma}_1^2)^{m/2} (\hat{\sigma}_2^2)^{n/2}}{\tau_0 (\hat{\sigma}_1^2)^{m+n/2}}$. The second form is $\frac{\left\{ \sum (x_i - \bar{x})^2 \right\}^{m/2} \left\{ \sum (y_j - \bar{y})^2 \right\}^{n/2}}{\left\{ \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right\}^{m+n/2}} < c_1$. The third form is $\frac{\left\{ \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right\}^{m+n/2}}{\left\{ \sum (x_i - \bar{x})^2 \right\}^{m/2} \left\{ \sum (y_j - \bar{y})^2 \right\}^{n/2}} > c_2$. A definition for u is circled: $u = \frac{\sum (y_j - \bar{y})^2}{\sum (x_i - \bar{x})^2}$. The NPTEL logo is visible in the bottom left corner.

Now, let me define u is equal to sigma y j minus y bar square divided by sigma x i minus x bar square. So, in terms of this ratio this condition can be written as.

(Refer Slide Time: 24:09)

In terms of u the rejection region can be written as

$$g(u) = \left(1 + \frac{u}{\tau_0}\right)^{m/2} \left(\frac{1}{u} + \frac{1}{\tau_0}\right)^{n/2} > c_2.$$

$$g'(u) = \frac{m}{2} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}-1} \frac{1}{\tau_0} \left(\frac{1}{u} + \frac{1}{\tau_0}\right)^{n/2} + \frac{n}{2} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}} \left(\frac{1}{u} + \frac{1}{\tau_0}\right)^{\frac{n}{2}-1} \left(-\frac{1}{u^2}\right)$$

$$\geq 0 \Leftrightarrow \frac{m}{\tau_0} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}-1} \geq \frac{n}{u^2} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}}$$

$$\Leftrightarrow \frac{m}{\tau_0} - \frac{n}{u} \geq 0 \Rightarrow u \geq \frac{n}{m} \tau_0.$$

So $g(u) \uparrow$ if $u \geq \frac{n}{m} \tau_0$
 \downarrow if $u < \frac{n}{m} \tau_0$.
 So $\lambda(x, y) < c_2 \Leftrightarrow u \geq \frac{n}{m} \tau_0$.

In terms of u the rejection region can be written as $1 + u$ by τ_0 to the power $m/2$ plus $1/u + 1/\tau_0$ to the power $n/2$ greater than say c_2 . Now let us consider this term as say g of u .

Then let us look at the g' of u that is equal to $m/2$ plus u by τ_0 to the power $m/2 - 1$ into $1/\tau_0$ plus $1/u + 1/\tau_0$ to the power $n/2$ plus $n/2$ plus $1 + u$ by τ_0 to the power $m/2$ plus $1/u + 1/\tau_0$ to the power $n/2 - 1$ minus $1/u^2$. So, this is greater than or equal to 0 if and only if. So, this will require certain simplification; I can take common $1 + u$ by τ_0 to the power $m/2 - 1$ and $1 + u$ by τ_0 to the power $n/2 - 1$. If I take this common and adjust the terms the condition is reducing to simply m/τ_0 into $1 + u$ by τ_0 greater than or equal to n/u^2 plus $1 + u$ by τ_0 . Which is equivalent to m/τ_0 minus n/u greater than or equal to 0 or u is greater than or equal to $n/m \tau_0$.

So, this function is actually having increasing nature. This g of u function; so, g of u is increasing if u is greater than or equal to $n/m \tau_0$ and it is decreasing if u is less than $n/m \tau_0$ but what is τ_0 ? That is σ_y^2 / σ_x^2 . So, the condition $\lambda(x, y) < c_2$ this is the equivalent to u greater than or equal to $n/m \tau_0$.

$$or. \frac{\sum (y_j - \bar{y})^2}{\sigma_2^2 (n-1)} / \frac{\sum (x_i - \bar{x})^2}{\sigma_1^2 (m-1)} > c_3.$$

$$\sup_{\frac{\sigma_2^2}{\sigma_1^2} = \tau_0} P \left(F_{n-1, m-1} > c_3 \right) \rightarrow \text{is attained at } \frac{\sigma_2^2}{\sigma_1^2} = \tau_0$$

$$\frac{\sum (y_j - \bar{y})^2}{\sigma_2^2 (n-1)} / \frac{\sum (x_i - \bar{x})^2}{\sigma_1^2 (m-1)} \sim F_{n-1, m-1}$$

$$So \quad c_3 \sim F_{n-1, m-1, \alpha}.$$

Or we can write it in the terms of sigma y j minus y bar square divided by sigma 2 square by n minus 1 divided by sigma x i minus x bar whole square divided by sigma 1 square m minus 1 that is greater than say some c 3.

Now, when I consider the probability of this region for sigma 2 square by sigma 1 square less than or equal to tau naught. Then supremum of this is attained at. So, you look at the distribution of this. This has sigma y j minus y bar whole square by sigma 2 square n minus 1 divided by sigma x i minus x bar whole square by sigma 1 square m minus 1. This follows F distribution on n minus 1; m minus 1 degrees of freedom.

So now, what we are saying is F n minus 1 m minus 1 greater than c 3. So, what we look at this that I adjust this term and I get here the maximum is attained at sigma 2 square by sigma 1 square is equal to tau naught. So, c 3 point then we take as F of n minus 1 m minus 1 alpha.

So the LRT rejects H_0 if

$$\frac{\sum (y_j - \bar{y})^2}{(n-1) \tau_0} / \frac{\sum (x_i - \bar{x})^2}{m-1} > F_{n-1, m-1, \alpha}$$

(Same as UMP unbiased test)

So, the test is; so, the likelihood ratio test rejects H_0 ; H_1 if $\sum y_j - \bar{y}$ square divided by $n - 1$ divided by σ_2 square divided by $\sum x_i - \bar{x}$ square divided by $m - 1$ is greater than $F_{n-1, m-1, \alpha}$.

Here τ_0 will be coming σ_2 square by σ_1 square. Yeah τ_0 will be coming here because here I should have σ_2 square by σ_1 square that is equal to τ_0 . So, same as the same as the UMP unbiased test that I derived that day. I will carry out the analysis for the equality test also. That is when we want to test that σ_2 square by σ_1 square is equal to τ_0 or against not equal to. And there of course, I can take the case where τ_0 is equal to 1. So, I will be discussing this case in the following lecture.

Moreover there is another important problem in testing of hypothesis. I have discussed two normal populations. Now in place of two normal population; we may have k normal population where k is can be 3, 4 and so on. And we may again like to test about the equality of means. So, the ump unbiasedness theory does not work, there because we cannot write the $\mu_1 = \mu_2$ etcetera in a form where which can be working as a multi parameter exponential family; however, for these situations a likelihood ratio test can be derived. So, this is the problem of testing homogeneity of means in a one way analysis of variance model. So, in the next lecture I will be discussing that also.
