Lecture – 57
Likelihood Ratio Tests – VII

In the last lecture, I introduce the problem of testing or you can say comparing the variances of two normal populations.

(Refer Slide Time: 00:33)

And we had considered one particular type of hypothesis problem that is sigma 2 square by sigma 1 square less than or equal to tau naught against sigma 2 square by sigma 1 square greater than tau naught. And the likelihood ratio test for this was derived.

(Refer Slide Time: 00:52)

Lecture 34

© CEE
IIT KGP

$H_4: \frac{\sigma_2^2}{\sigma_1^2} = \tau_0$
 $K_4: \frac{\sigma_2^2}{\sigma_1^2} \neq \tau_0$

$\Omega = \{\theta: \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1,2\}$
 $\Omega_{H_4} = \{\theta: \mu_i \in \mathbb{R}, \sigma_2^2 = \tau_0 \sigma_1^2, \sigma_i^2 > 0\}$

The likelihood function is

$$L(\theta, \mathbf{x}, \mathbf{y}) = \frac{1}{(2\pi\sigma_1^2)^{m/2} (2\pi\sigma_2^2)^{n/2}} e^{-\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\sigma_2^2}}$$

As in the previous problem the maximization of L over Ω gives

$$\hat{\mu}_{1\Omega} = \bar{x}, \hat{\mu}_{2\Omega} = \bar{y}, \hat{\sigma}_{1\Omega}^2 = \frac{1}{m} \sum (x_i - \bar{x})^2, \hat{\sigma}_{2\Omega}^2 = \frac{1}{n} \sum (y_j - \bar{y})^2$$

$\hat{L}(\Omega) =$

NPTTEL

Now, we will consider for the same model the hypothesis H_4 that is sigma 2 square by sigma 1 square is equal to tau naught against say sigma 2 square by sigma 1 square is not equal to tau naught ok.

(Refer Slide Time: 01:13)

Consider the likelihood function

© CEE
IIT KGP

$\Omega = \{\theta: \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1,2\}$
 $\Omega_{H_4} = \{\theta: \mu_i \in \mathbb{R}, \sigma_2^2 \leq \tau_0 \sigma_1^2, \sigma_i^2 > 0\}$

$L(\theta, \mathbf{x}, \mathbf{y}) = \frac{1}{(2\pi\sigma_1^2)^{m/2}} \cdot \frac{1}{(2\pi\sigma_2^2)^{n/2}} e^{-\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\sigma_2^2}}$

$l(\theta) = \log L = -\frac{m+n}{2} \log 2\pi - \frac{m}{2} \log \sigma_1^2 - \frac{n}{2} \log \sigma_2^2$
 $- \frac{1}{2\sigma_1^2} \sum (x_i - \mu_1)^2 - \frac{1}{2\sigma_2^2} \sum (y_j - \mu_2)^2$

$\frac{\partial l}{\partial \mu_1} = \frac{m(\bar{x} - \mu_1)}{\sigma_1^2} < 0$ for $\mu_1 > \bar{x}$
 > 0 for $\mu_1 < \bar{x}$ } So $\hat{\mu}_{1\Omega} = \bar{x}$

NPTTEL

So, we need not write the expressions once again. The likelihood function is given by 1 by 2 pi sigma 1 square to the power m by 2 1 by 2 pi sigma 2 square to the power n by 2 e to the power minus sigma x i minus mu 1 square by 2 sigma 1 square minus sigma y j minus mu 2 square by 2 sigma 2 square. In the previous problem, I considered the

maximization of this likelihood function over ω and ω_H , now in this case ω_H was σ_2^2 less than or equal to $\tau_0 \sigma_1^2$.

Now, in this new case, so let me repeat it here the log likelihood function the likelihood function and the log likelihood function, which we need to write. So, $L(\theta, x, y)$ that is equal to $\frac{1}{(2\pi\sigma_1^2)^m (2\pi\sigma_2^2)^n} e^{-\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\sigma_2^2}}$.

And we are having the ω is equal to μ_i belonging to \mathbb{R} and σ_i^2 is greater than 0 for i is equal to 1, 2; and ω_H is now θ μ_i belonging to \mathbb{R} and σ_2^2 is equal to $\tau_0 \sigma_1^2$ and of course, both are positive. Here our θ is μ_1, μ_2, σ_1^2 , and σ_2^2 .

Now, as in the previous problem, the maximization of L over ω gives $\hat{\mu}_1$ ω is equal to \bar{x} , $\hat{\mu}_2$ ω is equal to \bar{y} , $\hat{\sigma}_1^2$ ω is equal to $\frac{1}{m} \sum(x_i - \bar{x})^2$, this is m here, and $\hat{\sigma}_2^2$ ω is equal to $\frac{1}{n} \sum(y_j - \bar{y})^2$.

(Refer Slide Time: 04:17)

$\Omega_H = \{ \theta: \mu_i \in \mathbb{R}, \sigma_1^2 = \tau_0 \sigma_2^2, \sigma_i^2 > 0 \}$
 $K_4: \frac{\sigma_1^2}{\sigma_2^2} \neq \tau_0$
 The likelihood function is

$$L(\theta, x, y) = \frac{1}{(2\pi\sigma_1^2)^{m/2} (2\pi\sigma_2^2)^{n/2}} e^{-\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\sigma_2^2}}$$

 As in the previous problem the maximization of L over Ω gives
 $\hat{\mu}_{1\Omega} = \bar{x}, \hat{\mu}_{2\Omega} = \bar{y}, \hat{\sigma}_{1\Omega}^2 = \frac{1}{m} \sum(x_i - \bar{x})^2, \hat{\sigma}_{2\Omega}^2 = \frac{1}{n} \sum(y_j - \bar{y})^2$

$$\hat{L}(\Omega) = \frac{1}{(2\pi)^{\frac{m+n}{2}} (\hat{\sigma}_{1\Omega}^2)^{m/2} (\hat{\sigma}_{2\Omega}^2)^{n/2}} e^{-\frac{m+n}{2}}$$

And as a consequence $L(\hat{\omega})$ that is given by $L(\hat{\omega})$ is given by $\frac{1}{(2\pi)^{\frac{m+n}{2}} (\hat{\sigma}_1^2)^{m/2} (\hat{\sigma}_2^2)^{n/2}} e^{-\frac{m+n}{2}}$.

(Refer Slide Time: 04:59)

Consider maximization over Ω_H .

$$L(\theta, z, \xi) = \frac{1}{(2\pi\sigma_1^2)^{m/2} (2\pi\tau_0\sigma_1^2)^{n/2}} e^{-\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\tau_0\sigma_1^2}}$$

$$\ell(\theta, z, \xi) = \log L = -\frac{m+n}{2} \log 2\pi - \frac{n}{2} \log \tau_0 - \frac{m+n}{2} \log \sigma_1^2 - \frac{1}{2\sigma_1^2} \left[\sum(x_i - \mu_1)^2 + \frac{1}{\tau_0} \sum(y_j - \mu_2)^2 \right]$$

$$\hat{\mu}_{1|\Omega_H} = \bar{x}, \quad \hat{\mu}_{2|\Omega_H} = \bar{y}$$

$$\hat{\sigma}_{1|\Omega_H}^2 = \frac{1}{m+n} \left[\sum(x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum(y_j - \bar{y})^2 \right]$$

$$\hat{\sigma}_{2|\Omega_H}^2 = \tau_0 \hat{\sigma}_{1|\Omega_H}^2$$

Now, consider maximization over Ω_H . Now, when we consider over Ω_H , then the likelihood function gets little bit modified, over Ω_H L is equal to 1 by $2\pi\sigma_1^2$ to the power m by 2 , $2\pi\tau_0\sigma_1^2$ to the power n by 2 , because we are having σ_2^2 is equal to $\tau_0\sigma_1^2$, when we are considering Ω_H . And then you have e to the power minus $\frac{\sum(x_i - \mu_1)^2}{2\sigma_1^2} - \frac{\sum(y_j - \mu_2)^2}{2\tau_0\sigma_1^2}$.

So, of course, if we considered the log likelihood here \log of L that is equal to minus $\frac{m+n}{2} \log 2\pi - \frac{n}{2} \log \tau_0 - \frac{m+n}{2} \log \sigma_1^2 - \frac{1}{2\sigma_1^2} \left[\sum(x_i - \mu_1)^2 + \frac{1}{\tau_0} \sum(y_j - \mu_2)^2 \right]$.

So, if I consider μ_1 hat Ω_H that will be \bar{x} and μ_2 hat Ω_H that will be \bar{y} . However, if I consider maximization with respect to σ_1^2 hat square, I will get 1 by $m+n$ σ_1^2 $\sum(x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum(y_j - \bar{y})^2$ square. So, σ_2^2 hat Ω_H square that will be equal to τ_0 σ_1^2 hat Ω_H square.

(Refer Slide Time: 07:42)

$$L(\omega_k) = \frac{1}{(2\pi)^{\frac{m+n}{2}} \tau_0^{\frac{m+n}{2}} \left[\frac{1}{m+n} \left\{ \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right\} \right]^{\frac{m+n}{2}}}$$

The likelihood ratio test is then to Reject H_0 , when

$$\lambda(x, y) < c \text{ or } \frac{\left\{ \frac{1}{n} \sum (y_j - \bar{y})^2 \right\}^{n/2}}{\left[\frac{1}{m+n} \left\{ \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right\} \right]^{\frac{m+n}{2}}} < c$$

Let $u = \frac{\sum (y_j - \bar{y})^2}{\sum (x_i - \bar{x})^2}$

$$\text{or } g(u) = \left(1 + \frac{k}{\tau_0} \right)^{m/2} \left(\frac{1}{k} + \frac{1}{\tau_0} \right)^{n/2} > c_1$$

As a consequence if I substitute these values in the log likelihood function, so we get $L(\omega_H)$, I will get this value as $1 / (2\pi)^{(m+n)/2} \tau_0^{(m+n)/2} \left[\frac{1}{m+n} \left\{ \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right\} \right]^{(m+n)/2}$. So, this is the term that we will be getting.

Now, let us look at both of these terms here. We are having $L(\omega_H)$ as this term and $L(\omega_k)$ as this term. So, the likelihood ratio test can then be written as the likelihood ratio test is then to reject H_0 when $\lambda(x, y) < c$, which is equivalent to, now we have already derived the expression.

So, I will just substitute here $L(\omega_H)$, I will get this in the denominator, and then divided by $L(\omega_k)$. So, this will go in the numerator, so that gives me $\left[\frac{1}{n} \sum (y_j - \bar{y})^2 \right]^{n/2} / \left[\frac{1}{m+n} \left\{ \sum (x_i - \bar{x})^2 + \frac{1}{\tau_0} \sum (y_j - \bar{y})^2 \right\} \right]^{(m+n)/2} < c$.

Now, we take reciprocal of this and we use the notation say u is equal to $\sum (y_j - \bar{y})^2 / \sum (x_i - \bar{x})^2$. If we assume this, then we can rewrite this condition as $1 + u / \tau_0 > c_1$. Let us assume this to be $g(u)$. Now, this function, I considered in the yesterdays derivation of the test function.

(Refer Slide Time: 11:08)

In terms of u the rejection region can be written as

$$g(u) = \left(1 + \frac{u}{\tau_0}\right)^{m/2} \left(\frac{1}{k} + \frac{1}{\tau_0}\right)^{n/2} > c_2$$

$$g'(u) = \frac{m}{2} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}-1} \frac{1}{\tau_0} \left(\frac{1}{k} + \frac{1}{\tau_0}\right)^{n/2} - \frac{n}{2} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}} \left(\frac{1}{k} + \frac{1}{\tau_0}\right)^{\frac{n}{2}-1} \frac{1}{\tau_0}$$

$$\geq 0 \Leftrightarrow \frac{m}{\tau_0} \left(\frac{1}{k} + \frac{1}{\tau_0}\right) \geq \frac{n}{k^2} \left(1 + \frac{u}{\tau_0}\right)$$

$$\Leftrightarrow \frac{m}{\tau_0} - \frac{n}{k} \geq 0 \quad \text{or} \quad u \geq \frac{n}{m} \tau_0$$

So $g(u) \uparrow$ if $u \geq \frac{n}{m} \tau_0$
 \downarrow if $u < \frac{n}{m} \tau_0$.

So $\lambda(x, y) < c \Leftrightarrow u \geq \frac{n}{m} \tau_0$.

I will show the behavior of it here, I had assumed this term to be $g(u)$. Now, this term is same as this term here, and $g'(u)$ we had calculated.

(Refer Slide Time: 11:24)

$$\Leftrightarrow \frac{m}{\tau_0} - \frac{n}{k} \geq 0 \quad \text{or} \quad u \geq \frac{n}{m} \tau_0$$

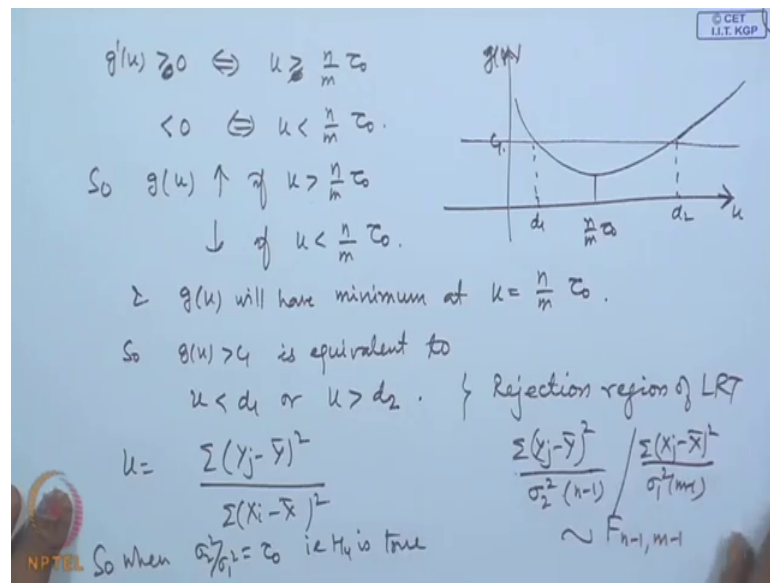

So $g(u) \uparrow$ if $u \geq \frac{n}{m} \tau_0$
 \downarrow if $u < \frac{n}{m} \tau_0$.

So $\lambda(x, y) < c \Leftrightarrow u \geq \frac{n}{m} \tau_0$.

$$g'(u) = \frac{1}{2} \left(1 + \frac{u}{\tau_0}\right)^{\frac{m}{2}-1} \left(\frac{1}{k} + \frac{1}{\tau_0}\right)^{\frac{n}{2}-1} \left[\frac{m}{\tau_0} \left(\frac{1}{k} + \frac{1}{\tau_0}\right) - \frac{n}{k^2} \left(1 + \frac{u}{\tau_0}\right) \right]$$

So, this $g'(u)$ function then turns out to be so I straight forwardly take the same expression, we obtain $g'(u)$ is equal to some term, which is equal to half of $1 + u$ by τ_0 to the power $m/2 - 1$ $1 + u$ plus 1 by τ_0 to the power $n/2 - 1$ $1 + u$ plus 1 by τ_0 minus n by u square $1 + u$ by τ_0 .

(Refer Slide Time: 12:13)

And this we can see as $g'(u)$, it will be greater than or equal to 0 if and only if u is greater than or equal to $\frac{n}{m} \tau_0$; and it will be less than 0 if u is less than $\frac{n}{m} \tau_0$. So, in fact, I can say greater here, greater here. So, $g(u)$ is increasing if u is greater than $\frac{n}{m} \tau_0$; it is decreasing if u is less than $\frac{n}{m} \tau_0$. And, $g(u)$ will have minimum at $u = \frac{n}{m} \tau_0$ that means, the nature of this $g(u)$ function will be something like this. There is a minimum at $u = \frac{n}{m} \tau_0$. If I am plotting $g(u)$ function, then it will have something like this.

So, if I say $g(u)$ is greater than c_1 . So, suppose this point is c_1 then this is equivalent to saying that u is either less than certain number or it is bigger than a certain number. So, let me call this number say d_1 and d_2 . So, $g(u) > c_1$ is equivalent to $u < d_1$ or $u > d_2$. So, this is the rejection region of likelihood ratio test. Now, this quantity u that is $\frac{\sum (y_j - \bar{y})^2}{\sum (x_i - \bar{x})^2}$ is equal to $\frac{\sigma_2^2 (n-1)}{\sigma_1^2 (m-1)}$ when H_0 is true.

So, if we considered this, we are having $\frac{\sum (y_j - \bar{y})^2}{\sigma_2^2 (n-1)}$ divided by $\frac{\sum (x_i - \bar{x})^2}{\sigma_1^2 (m-1)}$. This follows F distribution on $n-1$ and $m-1$ degrees of freedom. So, when $\frac{\sigma_2^2}{\sigma_1^2} = \tau_0$ that is H_0 is true.

(Refer Slide Time: 15:09)

then $\frac{u}{\tau_0} \sim F_{n-1, m-1}$.

So the Rejection region is

$$\frac{u}{\tau_0} < F_{n-1, m-1, 1-\frac{\alpha}{2}} \text{ or } \frac{u}{\tau_0} > F_{n-1, m-1, \frac{\alpha}{2}}$$

Theorem: Under regularity conditions on $f(x, \theta)$ the asymptotic distribution of $-2 \log \lambda(X)$ under H converges to a Chi-square distribution. The degrees of freedom are given by the difference in the number of independent parameters in Ω and those in Ω_H .

In the previous case eq. $-2 \log \lambda(X) \rightarrow \chi^2_1$

Then u by τ_0 that follows F distribution on $n - 1$ $m - 1$. So, the rejection region is u by τ_0 less than $F_{n-1, m-1, 1-\alpha/2}$ or u by τ_0 greater than $F_{n-1, m-1, \alpha/2}$. Of course, this is not necessary. I have taken the 2 points symmetric, but F distribution is not symmetric. So, the points may be at different places. So, this is $F_{m-1, n-1, 1-\alpha/2}$ point, and this point will be $F_{n-1, m-1, \alpha/2}$. So, this is the likelihood ratio test for the equality of the variances. And you can note here that this test is the same as the u and p and bias test, which I derived for this situation.

So, what we have shown here is that the likelihood ratio tests are applicable for the parameters of the normal distributions. Also they can be applied to some other distributions, where the distribution may not be of the normal type, it could be exponential, gamma, double exponential etcetera. The form of likelihood ratio test is such that it is general.

So, only condition is that you should be able to derive the maximum likelihood estimator for the full parameter space as well as under the parameter space which is restricted because of the null hypothesis. Once we have that the likelihood ratio test can be written. Now, it is a different matter that whether we can be able to derive the distribution of that are not.

Now, in many cases we may not be able to derive the exact distribution; however, there is a nice asymptotic property of the likelihood ratio test whichever I would like to state here. If you remember for the maximum likelihood estimators, we stated certain conditions which we called regularity conditions. For example, the density should be differentiable, the parameter space should be a subset of an open set in the Euclidean space. We had assumed that the density function or any expectation of a measurable integrable function should be differentiable under the integral sign. So, these were the regularity conditions.

Under those conditions, we had shown that the maximum likelihood estimator exists with probability one. And it is also consistent. And the asymptotic distribution of the maximum likelihood estimator was shown to be normal. Now, under the same regularity conditions, because here we are dealing with the likelihood function, so under the similarly likely regularity conditions the asymptotic distribution of the likelihood ratio test statistic can also be found.

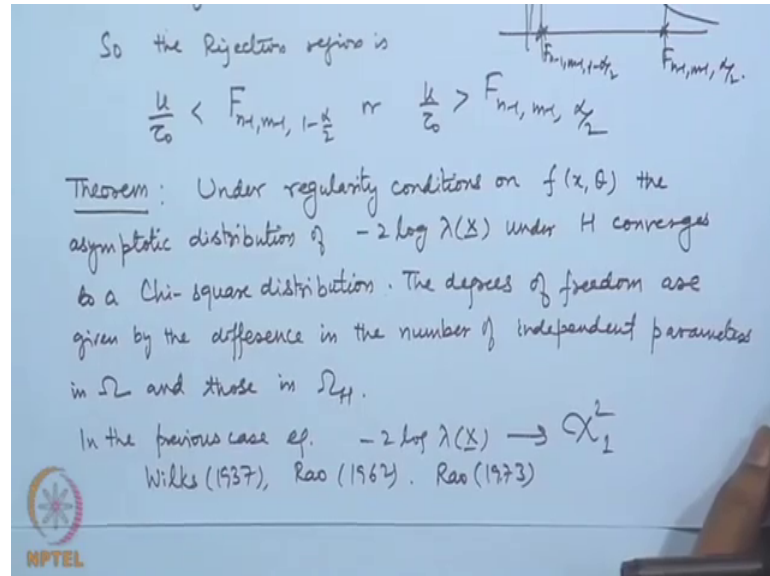

So, I will state the result without the proof here. Under regularity conditions on $f(x; \theta)$, the asymptotic distribution of $-2 \log \lambda(x)$ under H_0 converges to a chi square distribution. The degrees of freedom of the chi square, they are given by the difference in the number of independent parameters in Ω and those in Ω_0 . That means, when we are assuming the parameter is space, so we are getting for example, in the previous problem Ω had 4 dimension $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$.

Under Ω_0 we had 3 independent parameters, because μ_1, μ_2 are independent, but σ_1^2 and σ_2^2 were related. So, there were three independent parameters, so $4 - 3$, it will become 1. The number of degrees of freedom for chi square of (Refer Time: 20:22). So, basically what will get in the previous case for example, $-2 \log \lambda(x)$ will be converging to chi square 1 distribution.

Now, this is a very use full thing, because once the convergence is there, then one need not look for the exact distribution all the time. In certain cases, of course, like in the normal distribution cases exact distributions we are able to derive, but many times like in the discrete distributions either we have to deal with the distributions like binomial, Poisson or we have to look at the special tables like we had mentioned about the 2 by 2

contingency tables testing. So, in those cases, we can actually consider this approximation, and usually it is considered to be good.

(Refer Slide Time: 21:19)

More results about these things they are approved by Wilks 1937, Rao he has looked at the asymptotic convergence the rate of convergence of this, and there are many other authors who have actually considered the limiting distributions the book of Rao in 1973 discuss is in detail that Linear Statistical Inference book, they are discuss in detail the asymptotic properties of the likelihood function.

Now, I will consider two advance applications of this likelihood ratio test. So far whether I was discussing the ump test, ump unbiased test most powerful test I have considered, you can say simplistic situations, generally I was dealing with the univariate populations are bivariate populations, but in practice there can be even more complex situations. For example, I may have k-different populations, and I may like to check whether they are means or whether their variances are equal.

Now, in this case certainly the ump tests are ump unbiased tests are very difficult to derive. In fact, we cannot write down the form of the joint density function in a in the form of multi parameter exponential family, so that this parameter, which is to be considered occurs there. And therefore, the likelihood ratio test seems to be a good option only thing is we should be able to derive the maximum likelihood estimators under ω as well as under ω_H . So, I will give a couple of examples for

applications when we are dealing with multi parameter situations and the number of populations maybe more than two also.
