**Lecture – 58**  
**Likelihood Ratio Tests – VIII**

In practice there can be even more complex situations. For example, I may have  $k$  different populations and I may like to check whether their means or whether their variances are equal. Now in this case suddenly the UMP test or UMP unbiased tests are very difficult to derive. In fact, we cannot write down the form of the joint density function in a in the form of multi parameter exponential family so that this parameter which is to be considered occurs there.

And therefore, the likelihood ratio test seems to be a good option, only thing is we should be able to derive the maximum likelihood estimators under  $\omega$  as well as under  $\omega_0$ . So, I will give a couple of examples for applications when we are dealing with multiparameter situations and the number of populations may be more than two also.

(Refer Slide Time: 01:19)

So, the first one I will do likelihood ratio test for equality of means in one way analysis of variance model. So, the set up is like this we are having  $X_{11}$  and so on  $X_{1n_1}$  this is a random sample from say normal  $\mu_1$  sigma square.  $X_{21}$  and so on  $X_{2n_2}$  this is a

random sample from normal  $\mu_2$   $\sigma^2$  and so on.  $X_{k1}$  and so on,  $X_{kn}$  that is a random sample from normal  $\mu_k$   $\sigma^2$ . Note here I have taken the variances to be common. So, this is actually the situation of a one way analysis of variance model and we are considering the variances to be the same. Our testing problem is to test that whether the means are the same or not this is called homogeneity of that is means of are homogeneous; that means, the populations are homogeneous basically.

If  $\mu_i$  are the same then basically it means that we have same population against that  $\mu_i$ 's are not all equal. Now let me introduce some notation  $\theta$  is now  $\mu_1$   $\mu_2$   $\dots$   $\mu_k$   $\sigma^2$ . So, this  $k+1$  dimensional I will use the notation  $x$  for  $x_{11}$  and so on  $x_{1n_1}$  and so on,  $x_{kn}$  all the  $n_1$  plus  $n_2$  plus  $n_k$  observations that is  $\sum_{i=1}^k n_i = n$  calling a  $n$  these observations I call as  $x$ .

(Refer Slide Time: 03:52)

$\Omega = \{ \theta : \mu_i \in \mathbb{R}, \sigma^2 > 0 \}$   
 $\Omega_0 = \{ \theta : \mu_1 = \dots = \mu_k \in \mathbb{R}, \sigma^2 > 0 \}$   
 The likelihood function is  
 $L(\theta, x) = \frac{1}{(\sigma^2 \cdot 2\pi)^{n/2}} e^{-\frac{1}{2\sigma^2} \sum_{i=1}^k \sum_{j=1}^{n_i} (x_{ij} - \mu_i)^2}$   
 $l(\theta) = \log L = -\frac{n}{2} \log 2\pi - \frac{n}{2} \log \sigma^2 - \frac{1}{2\sigma^2} \sum \sum (x_{ij} - \mu_i)^2$   
 $\frac{\partial l}{\partial \mu_i} = \frac{n(\bar{x}_i - \mu_i)}{\sigma^2} > 0$  if  $\mu_i < \bar{x}_i$   
 $< 0$  if  $\mu_i > \bar{x}_i$  }  $\hat{\mu}_{i\Omega} = \bar{x}_i$   
 $\frac{\partial l}{\partial \sigma^2} = -\frac{n}{2\sigma^2} + \frac{1}{2\sigma^4} \sum \sum (x_{ij} - \mu_i)^2$

The parameter is phase, the full parameter is phase if we look at then the  $\mu_i$ 's belong to  $\mathbb{R}$  that is  $k$  dimension Euclidean space in to positive half of the real line and under  $\Omega_0$  you are dealing with 2-dimensional. Now the likelihood function is  $L(\theta, x)$  that is equal to  $1$  by  $\sigma^2 \cdot 2\pi$  to the power  $n/2$   $e$  to the power minus  $1/2$  by  $2\sigma^2$   $\sum_{i=1}^k \sum_{j=1}^{n_i} (x_{ij} - \mu_i)^2$ .

So, we take the log likelihood here that is  $-\frac{n}{2} \log 2\pi - \frac{n}{2} \log \sigma^2 - \frac{1}{2\sigma^2} \sum_{i=1}^k \sum_{j=1}^{n_i} (x_{ij} - \mu_i)^2$ . Now easily you can see that if I consider the derivative with respect to  $\mu_i$  then I will get  $n(\bar{x}_i - \mu_i) / \sigma^2$ .

$\mu_i$  divided by sigma square. So, this is greater than 0 for  $\mu_i$  less than  $\bar{x}_i$  and it is less than 0 if  $\mu_i$  is greater than  $\bar{x}_i$ . So, you get  $\mu_i \hat{\omega}$  is equal to  $\bar{x}_i$  because the maximum will occur at  $\bar{x}_i$ . Now we can see that the derivative with respect to sigma square and I get minus  $\frac{n}{2\sigma^4}$  times  $\sum \sum (x_{ij} - \mu_i)^2 - \sigma^2$  which I can write as minus  $\frac{n}{2\sigma^4}$  times  $\sum \sum x_{ij}^2 - 2\mu_i \sum x_{ij} + n\mu_i^2 - \sigma^2$ .

(Refer Slide Time: 06:20)

$$= -\frac{n}{2\sigma^4} \left[ \frac{1}{n} \sum \sum (x_{ij} - \mu_i)^2 - \sigma^2 \right] > 0 \text{ if } \sigma^2 < \frac{1}{n} \sum \sum (x_{ij} - \mu_i)^2$$

$$< 0 \text{ if } \sigma^2 > \dots$$

$$\text{So } \hat{\sigma}_n^2 = \frac{1}{n} \sum_{i=1}^k \sum_{j=1}^{n_i} (x_{ij} - \bar{x}_i)^2 = \frac{1}{n} S_W \rightarrow \text{within sample variation}$$

$$\text{So } \hat{L}(\Omega) = \frac{1}{(2\pi \hat{\sigma}_n^2)^{n/2}} e^{-\frac{n}{2}}$$

$$\text{For } \Omega_H: \mu_1 = \mu_2 = \dots = \mu_k = \mu \text{ (say)}$$

So, once again you can see it is greater than 0 if sigma square is less than  $\frac{1}{n} \sum \sum x_{ij}^2 - 2\mu_i \sum x_{ij} + n\mu_i^2$  and it is less than 0 if sigma square is greater than this. So; obviously, the maximization is occurring at this point and since  $\mu_i$  is estimated to be  $\bar{x}_i$ . So, we get sigma omega hat square that is equal to  $\frac{1}{n} \sum \sum x_{ij}^2 - 2\bar{x}_i \sum x_{ij} + n\bar{x}_i^2$ . I give a notation to this, this is equal to  $S_W$  that is 1 by n within sample variation because sigma  $\sum x_{ij} - \bar{x}_i$  whole square denotes the variation within the  $i$  x sample and then I am taking sum over all such.

So, this is the total variation within each sample I have considered here. So, if I consider  $\hat{L}(\Omega)$  that is by substituting the values of estimated values of sigma square and  $\mu_i$  I get  $\frac{1}{(2\pi \hat{\sigma}_n^2)^{n/2}} e^{-\frac{n}{2}}$ . Now for  $\Omega_H$  you are having  $\mu_1 = \mu_2 = \dots = \mu_k = \mu$  (say).

(Refer Slide Time: 08:27)

So  $\hat{L}(\Omega) = \frac{1}{(2\pi \hat{\sigma}_H^2)^{n/2}} e^{-\frac{1}{2} \dots}$

For  $\Omega_H: \mu_1 = \mu_2 = \dots = \mu_k = \mu$  (say)

reduces to a problem of single sample of  $n$  observations.

$\hat{\mu}_H = \frac{\sum n_i \bar{x}_i}{n}$

$\hat{\sigma}_H^2 = \frac{1}{n} \sum \sum (x_{ij} - \bar{x})^2 = \frac{1}{n} S_T \rightarrow$  (Total variation)

So, this actually becomes a problem of single sample, this reduces to a problem of single sample of  $n$  observations. So,  $\hat{\mu}_H$  will become simply  $\bar{x}$  that is  $\sum x_i$  divided by  $n$  and  $\hat{\sigma}_H^2$  will become equal to  $\frac{1}{n} \sum (x_{ij} - \bar{x})^2$ , which I call as  $\frac{1}{n} S_T$  that is the total variation ok. Because I am considering the difference of each unit from the grand mean and then I am taking the sum of the squares here this is the total variation.

(Refer Slide Time: 09:37)

$S_T = \sum_{i=1}^k \sum_{j=1}^{n_i} (x_{ij} - \bar{x})^2 = \sum \sum (x_{ij} - \bar{x}_i + \bar{x}_i - \bar{x})^2$

$= \sum \sum (x_{ij} - \bar{x}_i)^2 + \sum n_i (\bar{x}_i - \bar{x})^2$

$= S_W + S_B \rightarrow$  variation between samples

$\hat{L}(\Omega_H) = \frac{1}{(2\pi \hat{\sigma}_H^2)^{n/2}} e^{-\frac{1}{2} \dots}$

$\lambda(\underline{x}) = \frac{\hat{L}(\Omega_H)}{\hat{L}(\Omega_A)} = \left( \frac{\hat{\sigma}_H^2}{\hat{\sigma}_A^2} \right)^{n/2} < c$

$\Leftrightarrow \frac{S_W}{S_B + S_W} < c_1 \Leftrightarrow \frac{S_B}{S_W} > c_2$  or  $\frac{S_B/(k-1)}{S_W/(n-k)} > c_3$

So, this purpose of writing this  $S_W$  and  $S_T$  is to explain the type of terms that we are getting and this  $S_T$  you can actually write as double summation  $\sum_{ij} (x_{ij} - \bar{x})^2$ , here you add and subtract  $\bar{x}$ . So, this gives me  $\sum_{ij} (x_{ij} - \bar{x} + \bar{x} - \bar{x})^2$ . So, this becomes  $\sum_{ij} (x_{ij} - \bar{x})^2 + \sum_{ij} (\bar{x} - \bar{x})^2 - 2 \sum_{ij} (x_{ij} - \bar{x})(\bar{x} - \bar{x})$ .

So, this is equal to  $S_W$  plus  $S_B$ , now this  $S_B$  this term is actually variation between samples because we are considering  $\bar{x}_i$  that is  $i$  x sample mean and  $\bar{x}$  is the grand mean. So, this is nothing, but the and then I am taking square and then taking all such cases. So, this is actually how much variation is there between the different samples.

So, now, we can utilize this and write down the form of  $L_{\hat{\omega}_H}$ . So, that turns out to be simply  $\frac{1}{2\pi} e^{-\frac{n}{2}}$ . So, let us look at these two terms here that we are getting now,  $L_{\hat{\omega}_H}$  here  $e^{-\frac{n}{2}}$  and here  $\sigma_{\hat{\omega}_H}^2$  to the power  $\frac{n}{2}$ , where  $\sigma_{\hat{\omega}_H}$  is the  $S_W$  by  $n$  term.

And in  $L_{\hat{\omega}_H}$  I get the same thing, here only  $\omega_H$  is replaced and the value of  $\omega_H$  that we calculated as  $S_T$  by  $n$  and this  $S_T$  I wrote again as  $S_W$  plus  $S_B$ . Therefore, the form of the likelihood ratio test that is  $\lambda$  that is  $L_{\hat{\omega}_H}$  by  $L_{\hat{\omega}_0}$  that becomes equal to  $\frac{\sigma_{\hat{\omega}_H}^2}{\sigma_{\hat{\omega}_0}^2}$  to the power  $\frac{n}{2}$  less than  $C$  which is equivalent to now by because of writing down this equation  $\frac{S_W}{S_B + S_W}$  less than  $C$ . Then you take the reciprocal and subtract 1, so we get greater than  $C$  or we can write  $S_B$  divided by  $k$  minus 1 divided by  $S_W$  divided by  $n$  minus  $k$  greater than say some  $C$ .

(Refer Slide Time: 12:43)

$$\hat{L}(\Omega_H) = \frac{1}{(2\pi \hat{\sigma}_H^2)^{n/2}} e^{-1/2}$$

$$\lambda(x) = \frac{\hat{L}(\Omega_H)}{\hat{L}(\Omega_U)} = \left( \frac{\hat{\sigma}_H^2}{\hat{\sigma}_U^2} \right)^{n/2} < c$$

$$\Leftrightarrow \frac{S_W}{S_B + S_W} < c_1 \Leftrightarrow \frac{S_B}{S_W} > c_2 \text{ or } \frac{S_B/(k-1)}{S_W/(n-k)} > c_3$$

Under  $H: \mu_1 = \dots = \mu_k$ ,  
One way ANOVA

$$\frac{S_B/(k-1)}{S_W/(n-k)} \sim F_{k-1, n-k}$$

Now, under  $H$  that is  $\mu_1$  is equal to  $\mu_2$  is equal to  $\mu_k$  this  $S_B$  that is  $S_B$  by  $k$  minus 1 divided by  $S_W$  by  $n$  minus  $k$ , this follows  $F$  distribution on  $k$  minus 1  $n$  minus  $k$  degrees of freedom. So, this point  $C$  then is nothing, but a point on the curve of the density of  $F_{k-1, n-k}$  distribution that is the upper handed  $\alpha$  percent point this probability is  $\alpha$ . So, then this is  $F$  of  $k$  minus 1  $n$  minus  $k$   $\alpha$ .

So, this is a usual test which is there in the one way analysis of variance, for testing the homogeneity of the means. I will repeat this problem, I made the assumption here that the variances are common. But when we are discussing general sampling from various populations then many times this assumption needs to be checked; that means, we are not sure whether variances are of same, if the variances are to be checked then we can derive a likelihood ratio test for this also. Let me just give a brief sketch of this likelihood ratio test here.

(Refer Slide Time: 14:26)

Testing for Homogeneity of Variances

$(X_{i1}, \dots, X_{in_i}) \sim N(\mu_i, \sigma_i^2), i=1, \dots, k$   
 (the  $k$  samples are taken independently)

$H_0: \sigma_1^2 = \sigma_2^2 = \dots = \sigma_k^2$   
 $K: \text{not all } \sigma_i^2 \text{ are equal}$

$\underline{\theta} = (\mu_1, \dots, \mu_k, \sigma_1^2, \dots, \sigma_k^2)$

$\Omega = \{ \underline{\theta}: \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1, \dots, k \}$

$\Omega_{H_0} = \{ \underline{\theta}: \mu_i \in \mathbb{R}, i=1, \dots, k, \sigma_1^2 = \dots = \sigma_k^2 = \sigma^2 > 0 \}$

Let me consider testing for homogeneity of variances. So, you have seen actually this likelihood ratio test is applicable to very very general situations, I considered a  $k$  population model and I could actually derive an exact test. Now here let us consider the sampling  $X_{i1} X_{i2} \dots X_{in_i}$ , this is from normal  $\mu_i \sigma_i^2$  for  $i$  is equal to 1 to  $k$  and the  $k$  samples are taken independently.

So, our hypothesis is  $\sigma_1^2 = \sigma_2^2 = \dots = \sigma_k^2$  against not all  $\sigma_i^2$  are equal our parameter phase has become little bit larger, it is actually  $2k$  dimensional now. The parameter  $\theta$  is actually  $\mu_1 \mu_2 \dots \mu_k \sigma_1^2 \sigma_2^2 \dots \sigma_k^2$ .

The full parameter space is that this  $\mu_i$  s are real numbers and  $\sigma_i^2$  are the positive real numbers and under  $\Omega_{H_0}$  it becomes  $k+1$  dimensional because  $\mu_i$  is remain as such, but  $\sigma_1^2$  squares become equal. So, the dimension of this part has reduced to 1.

(Refer Slide Time: 16:50)

(The  $k$  samples are taken independently)

$$H: \sigma_1^2 = \sigma_2^2 = \dots = \sigma_k^2$$

$$K: \text{not all } \sigma_i^2 \text{'s are equal}$$

$$\underline{\theta} = (\mu_1, \dots, \mu_k, \sigma_1^2, \dots, \sigma_k^2)$$

$$\Omega = \{ \underline{\theta}: \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1, \dots, k \}$$

$$\Omega_H = \{ \underline{\theta}: \mu_i \in \mathbb{R}, i=1, \dots, k, \sigma_1^2 = \dots = \sigma_k^2 = \sigma^2 > 0 \}$$

$$L(\underline{\theta}, \mathcal{Z}) = \prod_{i=1}^k \left[ \frac{1}{(\sqrt{2\pi} \sigma_i)^{n_i}} e^{-\frac{1}{2\sigma_i^2} \sum_{j=1}^{n_i} (x_{ij} - \mu_i)^2} \right]$$

So, this is  $k$ ; so  $k$  plus 1 dimensional. Now as before I will not do the detailed calculations here. The likelihood function that is equal to since I have to write for the  $k$  different populations I am writing it in this form product  $i$  is equal to 1 to  $k$  1 by root  $2\pi$  sigma  $i$  to the power  $n_i$   $e$  to the power minus 1 by 2 sigma  $i$  square sigma  $x_{ij}$  minus  $\mu_i$  square  $j$  is equal to 1 to  $n_i$ .

(Refer Slide Time: 17:28)

$$= \frac{1}{\prod \sigma_i^{n_i} (2\pi)^{n/2}} e^{-\frac{1}{2} \sum_{i=1}^k \sum_{j=1}^{n_i} \frac{(x_{ij} - \mu_i)^2}{\sigma_i^2}}$$

© CET  
I.I.T. KGP  
 $\sum n_i = n$

$$l(\underline{\theta}, \mathcal{Z}) = \log L = -\frac{n}{2} \log (2\pi) - \sum \frac{n_i}{2} \log \sigma_i^2 - \frac{1}{2} \sum_i \sum_j \frac{(x_{ij} - \mu_i)^2}{\sigma_i^2}$$

Proceeding as in earlier cases, the maximum likelihood estimates of the parameters are obtained as

$$\hat{\mu}_{i,\Omega} = \bar{x}_i, \quad \hat{\sigma}_{i,\Omega}^2 = \frac{1}{n_i} \sum_{j=1}^{n_i} (x_{ij} - \bar{x}_i)^2, \quad i=1, \dots, k$$

Under  $\Omega_H$ :

$$l(\underline{\theta}, \mathcal{Z}) = -\frac{n}{2} \log (2\pi) - \frac{n}{2} \log \sigma^2 - \frac{1}{2\sigma^2} \sum \sum (x_{ij} - \mu_i)^2$$

We can simplify this that is equal to 1 by product sigma i to the power n i 2 pi to the power n by 2 where sigma n i is equal to n then e to the power minus half sigma x ij minus mu i by sigma i square I is equal to 1 to k and j is equal to 1 to n i.

So, we take the log likelihood function that is equal to minus n by 2 log of 2 pi minus sigma n i by 2 log of sigma i square minus 1 by 2 sigma i square sigma ok. Let me write it as minus half double summation x ij minus mu i square by sigma i square. So, we can easily see that if I consider the usual maximization with respect to mu i s it will occur at x i bars and if I do with respect to sigma i square I will get it at 1 by n i sigma x ij minus x bar square.

So, proceeding as in earlier cases the maximum likelihood estimates of the parameters mu i omega hat is equal to x i bar and sigma i omega hat square that is equal to 1 by n i sigma x ij minus x i bar square j is equal to 1 to n i i is equal to 1 to k. Under omega H that is when we are taking sigma 1 square is equal to sigma 2 square is equal to sigma square then this l gets modified l will become minus n by 2 log of 2 pi minus n by 2 log of sigma square minus 1 by 2 sigma, square double summation x ij minus mu i square.

(Refer Slide Time: 20:39)

Now maximization yields

$$\hat{\mu}_{i\Omega_H} = \bar{x}_i, \quad \hat{\sigma}_{i\Omega_H}^2 = \frac{1}{n} \sum \sum (x_{ij} - \bar{x}_i)^2.$$

So  $\hat{L}(\Omega) = \prod_{i=1}^k \frac{1}{(2\pi)^{n_i/2} (\hat{\sigma}_{i\Omega}^2)^{n_i/2}} e^{-\frac{n_i}{2}}$

$$= \frac{e^{-n/2}}{(2\pi)^{n/2}} \cdot \frac{1}{\prod_{i=1}^k (\hat{\sigma}_{i\Omega}^2)^{n_i/2}}$$

$$\hat{L}(\Omega_H) = \frac{e^{-n/2}}{(2\pi)^{n/2} (\hat{\sigma}_{\Omega_H}^2)^{n/2}}.$$

So, now if we consider the maximization, maximization yields mu i omega H hat as before that is x i bar, but the value of sigma i omega H hat square that becomes 1 by n double summation x ij minus x i bar square. So, L hat omega and L hat omega H can be calculated, I will write down the simplified expressions here that is product I is equal to 1

to  $k-1$  by  $2\pi$  to the power  $n$   $i$  by  $2$   $\sigma_i$   $\hat{\omega}$  square ok, square part you can remove to the power  $n$   $i$ .

And then we get if I write the square here then  $n$   $i$  by  $1$  I can write  $e$  to the power minus  $n$   $i$  by  $1$  that is equal to  $e$  to the power minus  $n$  by  $2$  divided by  $2\pi$  to the power  $n$  by  $2$ ,  $1$  by product  $\sigma_i$   $\hat{\omega}$  square to the power  $n$   $i$  by  $2$   $i$  is equal to  $1$  to  $k$ . And  $L$  hat  $\omega$  H that is equal to  $1$  by  $2\pi$  to the power  $n$  by  $2$   $e$  to the power minus  $n$  by  $2$  and  $\sigma_i$   $\hat{\omega}$  H hat square to the power  $n$  by  $2$ .

(Refer Slide Time: 22:39)

The image shows a handwritten derivation of Bartlett's test statistic. At the top, it defines  $\lambda(z) = \frac{\prod_{i=1}^k (\hat{\sigma}_{i,z}^2)^{n_i/2}}{(\hat{\sigma}_{z,H}^2)^{n/2}} < C$ . Below this, it shows an equivalent form:  $\Leftrightarrow \frac{\prod_{i=1}^k \left[ \frac{1}{n_i} \sum_{j=1}^{n_i} (x_{ij} - \bar{x}_i)^2 \right]^{n_i/2}}{\left[ \frac{1}{n} \sum_{i=1}^k \sum_{j=1}^{n_i} (x_{ij} - \bar{x}_i)^2 \right]^{n/2}} < C$ . The text "The exact tables of this test are provided by R.E. Glaser (1976, J. Amer. Statist. Assoc.)" is written below the equations. To the right, it notes "The asymptotic dist<sup>n</sup> -  $2 \log \lambda(z) \sim \chi^2_{k-1}$ ". The slide also includes a logo for NPTEL and a copyright notice for CET I.I.T. KGP.

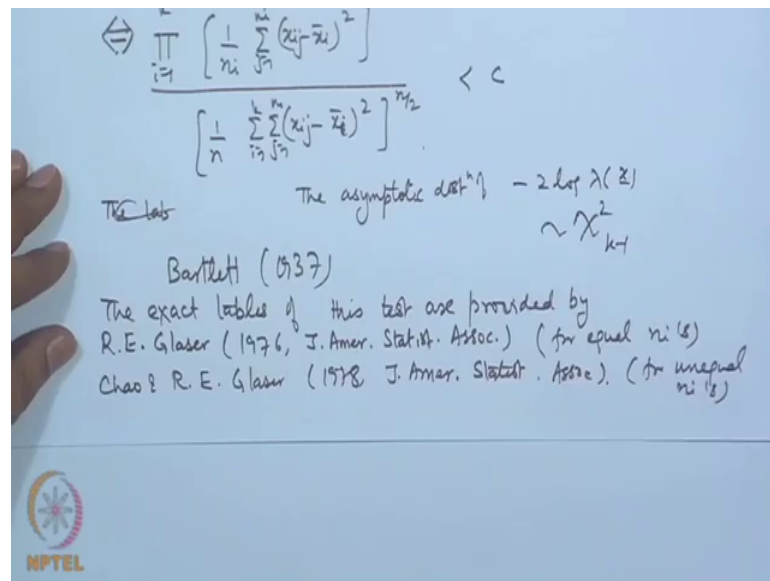

So,  $\lambda(z)$  that is equal to  $\sigma_i$   $\hat{\omega}$  square product  $i$  is equal to  $1$  to  $k$  to the power  $n$   $i$  by  $2$  divided by  $\sigma_i$   $\hat{\omega}$  H hat square to the power  $n$  by  $2$ . So, this less than  $C$ , this is equivalent to saying that now this  $\sigma_i$   $\hat{\omega}$  hat that we have already written the expression that is  $1$  by  $n$   $i$   $\sigma_i$   $x_{ij}$  minus  $\bar{x}_i$  square to the power  $n$   $i$  by  $2$  product  $i$  is equal to  $1$  to  $k$  divided by  $1$  by  $n$  double summation  $x_{ij}$  minus  $\bar{x}_i$  square. This is  $j$  is equal to  $1$  to  $n_i$   $j$  is equal to  $1$  to  $n_i$   $i$  is equal to  $1$  to  $k$  whole to the power  $n$  by  $2$  less than  $C$ .

So, basically it is in the terms of the sums of the squares and this is as we have already defined it is the within sample variance for each sample and this is the total variance sample thing. So, this is coming in terms of the sum of that earlier we got 2-dimensional sum that is  $S_B$  plus  $S_W$  thing here I am getting  $k$  dimensional terms here, the tables actually the exact distribution of this is not so simple; however, it has been derived. But

if we use the asymptotic distribution that will become chi square on how many degrees of freedom  $2k - k + 1$ .

So, if I consider the asymptotic distribution here of  $-2 \log \lambda$  that is chi square on  $k - 1$  degrees of freedom. So, this was provided by Bartlett in 1937 and the exact tables of this test are provided by R E Glaser in 1976 in Journal of American Statistical Association.

(Refer Slide Time: 25:45)

This part he considered for equal sample sizes and for unequal sample sizes Chao and R E Glaser in 1978 Journal of American Statistical Association, this is for unequal  $n_i$ s, this test is shown to be unbiased test. So, there are desirable properties of this test that are known. So, if we use this test to check the equality of the variances and if the equality is there then we can apply the one way analysis of variance test for  $\mu_1 = \mu_2 = \dots = \mu_k$ . And so what I have demonstrated here that the likelihood ratio test gives the solutions here.

Whereas, we cannot directly apply any result for the UMP or UMP unbiased test theory here, those things are not applicable here. Let me take up another problem here which is related. Earlier I have explained one problem testing for independence in a contingency table. Now in a contingency table you are having two attributes, but when we have quantitative data then how to test the independence. So, the simplest model that we can think of is a bivariate normal population.

Now we know that in a bivariate normal population you have five parameters; that means, the two means the two variances and then there is a correlation coefficient rho. And it has been it is known that the independence is equivalent to rho being equal to 0 in the bivariate normal population independence condition and the uncoded conditions are the same.

So, if we test rho is equal to 0 in a bivariate normal setting then it becomes the test for independence. Let me show that a likelihood ratio test can be derived here.

(Refer Slide Time: 27:57)

© CET  
I.I.T. KGP

Testing for Independence in Bivariate Normal Distribution

Let  $(X_1, Y_1), \dots, (X_n, Y_n)$  be a random sample from  
 $BVN(\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho)$  population

$H: \rho = 0$  vs  $K: \rho \neq 0$        $\underline{\theta} = (\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho)$

$\Omega = \{ \underline{\theta} : \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1,2, -1 < \rho < 1 \}$

$\Omega_H = \{ \underline{\theta} : \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1,2, \rho = 0 \}$

$L(\underline{\theta}; (X, Y)) = \frac{1}{[2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}]^n} e^{-\frac{1}{2(1-\rho^2)} \sum \left[ \left(\frac{x_i - \mu_1}{\sigma_1}\right)^2 + \left(\frac{y_i - \mu_2}{\sigma_2}\right)^2 - 2\rho \left(\frac{x_i - \mu_1}{\sigma_1}\right) \left(\frac{y_i - \mu_2}{\sigma_2}\right) \right]}$

$l(\underline{\theta}) = \log L = -\frac{n}{2} \log 2\pi - \frac{n}{2} \log(1-\rho^2) - \frac{1}{2(1-\rho^2)} \sum \left[ \left(\frac{x_i - \mu_1}{\sigma_1}\right)^2 + \left(\frac{y_i - \mu_2}{\sigma_2}\right)^2 - 2\rho \left(\frac{x_i - \mu_1}{\sigma_1}\right) \left(\frac{y_i - \mu_2}{\sigma_2}\right) \right]$

So, this will be my last example in the likelihood ratio test and then we will proceed to another theory here. So, testing for independence in bivariate normal distributions. So, let  $X_1, Y_1, X_2, Y_2, \dots, X_n, Y_n$  be a random sample from bivariate normal  $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho$  population. And we want to test the hypothesis whether rho is equal to 0 against rho is not equal to 0, this is the condition for the independence our parameter here is the 5-dimensional  $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2, \rho$ . The full parameter space here is  $\mu_i$  are real  $\sigma_i^2$  are positive and rho lies between minus 1 and 1.

Under the null hypothesis the dimension becomes one less,  $\mu_i$ 's and  $\sigma_i^2$  squares remain the same; however, rho becomes 0. So, the likelihood function here that is equal to  $\frac{1}{(2\pi\sigma_1\sigma_2)^n} e^{-\frac{1}{2} \sum \left[ \frac{(x_i - \mu_1)^2}{\sigma_1^2} + \frac{(y_i - \mu_2)^2}{\sigma_2^2} \right]}$

by  $\sigma_2^2$  square minus  $2\rho x_i$  minus  $\mu_1$  by  $\sigma_1$   $y_i$  minus  $\mu_2$  by  $\sigma_2$ .  
 Now you take the log likelihood here.

(Refer Slide Time: 30:50)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it states  $H: \rho = 0$  vs  $K: \rho \neq 0$  and  $-1 < \rho < 1$ . Below this, the parameter space  $\Omega = \{ \theta : \mu_i \in \mathbb{R}, \sigma_i^2 > 0, i=1,2, \rho=0 \}$  is defined. The likelihood function is given as  $L(\theta, (x, y)) = \frac{1}{[2\pi\sigma_1\sigma_2\sqrt{1-\rho^2}]^n} e^{-\frac{1}{2(1-\rho^2)} \sum [(\frac{x_i-\mu_1}{\sigma_1})^2 + (\frac{y_i-\mu_2}{\sigma_2})^2 - 2\rho(\frac{x_i-\mu_1}{\sigma_1})(\frac{y_i-\mu_2}{\sigma_2})]}$ . The log-likelihood is then derived as  $l(\theta) = \log L = -\frac{n}{2} \ln(2\pi) - \frac{n}{2} \ln \sigma_1^2 - \frac{n}{2} \ln \sigma_2^2 - \frac{n}{2} \ln(1-\rho^2) - \frac{1}{2(1-\rho^2)} \left[ \frac{\sum (x_i-\mu_1)^2}{\sigma_1^2} + \frac{\sum (y_i-\mu_2)^2}{\sigma_2^2} - 2\rho \frac{\sum (x_i-\mu_1)(y_i-\mu_2)}{\sigma_1\sigma_2} \right]$ .

And that is equal to minus  $n$  by  $2 \log$  of  $2\pi$  minus  $n$  by  $2 \log$  of  $\sigma_1^2$  square minus  $n$  by  $2 \log$  of  $\sigma_2^2$  square minus  $n$  by  $2 \log$  of  $1 - \rho^2$  square and then this expression that is minus  $1$  by twice  $1 - \rho^2$  sigma  $x_i$  minus  $\mu_1$  square by sigma  $1$  square plus sigma  $y_i$  minus  $\mu_2$  square by sigma  $2$  square minus twice rho sigma  $x_i$  minus  $\mu_1$  in to  $y_i$  minus  $\mu_2$  divided by sigma  $1$  sigma  $2$ .

Now, if we proceed in the usual fashion for the maximization with respect to the parameters for  $\mu_i$ 's I will get the sample means and for the  $\sigma_i^2$  squares we will get the sample variances and for  $\rho$  I will get the sample correlation coefficient.

Maximum likelihood estimates for parameters are

$$\hat{\mu}_{1\Omega} = \bar{x}, \quad \hat{\mu}_{2\Omega} = \bar{y}, \quad \hat{\sigma}_{1\Omega}^2 = \frac{1}{n} \sum (x_i - \bar{x})^2, \quad \hat{\sigma}_{2\Omega}^2 = \frac{1}{n} \sum (y_i - \bar{y})^2$$

$$\hat{\rho}_{\Omega} = r = \frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum (x_i - \bar{x})^2} \sqrt{\sum (y_i - \bar{y})^2}}$$

When  $\rho=0$ , the ml estimates except  $\rho$  remain same

So  $\hat{L}(\Omega) = \frac{1}{(2\pi \hat{\sigma}_{1\Omega} \hat{\sigma}_{2\Omega} \sqrt{1-r^2})^n} e^{-n}$

$\hat{L}(\Omega_H) = \frac{1}{(2\pi \hat{\sigma}_{1\Omega} \hat{\sigma}_{2\Omega})^n} e^{-n}$

So, without getting in to too much of the derivations let me write the final answers here. So, the maximum likelihood estimates for parameters are. So,  $\mu_1$  omega hat that is equal to  $\bar{x}$ ,  $\mu_2$  omega hat is equal to  $\bar{y}$   $\sigma_1$  omega hat square is equal to  $\frac{1}{n} \sum (x_i - \bar{x})^2$ ,  $\sigma_2$  omega hat square is equal to  $\frac{1}{n} \sum (y_i - \bar{y})^2$ . And  $\rho$  hat omega that is equal to  $r$  that is equal to  $\frac{\sum (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum (x_i - \bar{x})^2} \sqrt{\sum (y_i - \bar{y})^2}}$ . So, it will become equal to  $\frac{1}{2\pi \hat{\sigma}_{1\Omega} \hat{\sigma}_{2\Omega} \sqrt{1-r^2}}$  to the power  $n$   $e^{-n}$ .

Now, when  $\rho$  is equal to 0 then the ml estimates except  $\rho$  remain same. So, we get then  $\hat{L}(\Omega_H)$  that is equal to  $\frac{1}{(2\pi \hat{\sigma}_{1\Omega} \hat{\sigma}_{2\Omega})^n} e^{-n}$  and in  $\hat{L}(\Omega_H)$  except this term all other things will be same. So, it will become equal to  $\frac{1}{2\pi \hat{\sigma}_{1\Omega} \hat{\sigma}_{2\Omega}}$  to the power  $n$   $e^{-n}$ .

(Refer Slide Time: 34:02)

So LRT is to reject  $H_0$  if  
 $\lambda(x) < c \Leftrightarrow (1-r^2)^{n/2} < c$   
 $\Leftrightarrow |r| > c$

Under  $\rho=0$   $T = \sqrt{n-2} \cdot \frac{r}{\sqrt{1-r^2}} \sim t_{n-2}$

So we can write the test in terms of  $t_{n-2}$

$|T| > t_{n-2, \alpha/2}$

So, the test is simply reducing to so the likelihood ratio test is to reject  $H_0$  if  $\lambda(x)$  is less than  $c$  which is equivalent to saying one minus  $r$  square to the power  $n$  by  $2$  is less than  $C$ , which is also equivalent to saying modulus  $r$  is greater than  $C$ . Now under  $\rho$  is equal to  $0$  that is under  $H_0$ , the distribution of  $t$  that is  $\sqrt{n-2} \cdot r / \sqrt{1-r^2}$  this is  $t$  on  $n-2$  degrees of freedom and this term is increasing in  $r$ . So, we can write the test in terms of  $t_{n-2}$ .

So, basically what we can say we reject when modulus  $T$  is greater than  $t_{n-2, \alpha/2}$  because  $t$  distribution is symmetric. So, we can consider this  $\alpha/2$  and this probability has  $\alpha/2$  here this is the acceptance region. So, you can see here also we are able to nicely get the likelihood ratio test for testing for the independence in a bivariate normal population. I have discussed in detail the large sample test this likelihood ratio test which is having a large sample optimality property that is the asymptotic distribution is chi square.

And I have derived the exact distributions for testing problems in the normal populations and also some examples in binomial or exponential distributions also have been worked out. In the next lecture I will consider another concept that is of invariance in the testing problems.
