**Lecture-28**  
**Proof of the First (Homotopy) Version of the Monodromy Theorem**

(Refer Slide Time: 00:05)

(Refer Slide Time: 00:09)

(Refer Slide Time: 00:18)

**Goals of Lecture 28:**

**\*\* Analytic continuation is important as it allows moving from a given analytic branch of a multi-valued function to another branch, thus allowing all the branches to be found starting with a given branch...**

(Refer Slide Time: 00:25)

**Goals of Lecture 28:**

**\*\*\* In earlier lectures, it was shown that the notion of analytic continuation via power series with centres varying along a path can be seen as a finite chain of direct analytic continuations. The continuous dependence on the path variable, of each of the coefficients in the family of power series defining an analytic continuation along a path was also established. It was further shown that for a parametrised path and a given analytic function at the initial point of the path, the analytic continuations at later points along the path are unique. Moreover, the notion of a function being analytically continuable along a given path was introduced and examples of analytically continuable functions as well as of functions not analytically continuable on certain paths were given**

(Refer Slide Time: 00:33)

**Goals of Lecture 28:**

\*\*\*\* In more recent lectures, the dependence of analytic continuation on the path was explained by introducing the homotopy version of the so-called Monodromy theorem which asserts independence for paths that are fixed-end-point homotopic and have no obstructions to analytic continuation at any stage of the homotopy. The notions of a maximal domain of direct analytic continuation and that of a maximal domain of indirect analytic continuation (or domain of regularity) were introduced. While a maximal domain of direct analytic continuation need not be unique, a maximal domain of indirect analytic continuation (or domain of regularity) is unique. The second version of the Monodromy theorem asserts that when the domain of regularity is simply connected and unobstructed, then it coincides with any maximal domain of direct analytic continuation, which implies that in such cases we can speak of "the" maximal domain of direct analytic continuation as it is unique. The second (simply connected) version of the Monodromy theorem was deduced from the first (homotopy) version and the first was in turn deduced from the second for unobstructed domains...

(Refer Slide Time: 00:41)

**Goals of Lecture 28:**

\*\*\*\*\* In the last lecture, we proved that analytic continuations exist and moreover give rise to the same final (analytically continued) function for all paths sufficiently close to a given path along which analytic continuation is already known to exist. This key result is used to prove the first (homotopy) version of the Monodromy theorem in the present lecture

(Refer Slide Time: 00:49)

**Keywords for Lecture 28:**  
 parametrisation of a path, analytic function defined by a power series, analytic continuation using power series, continuously varying family of power series depending on one real parameter, 1-parameter family of power series, analytic continuability along a path, analytically continuable function, obstruction to analytic continuation, trivial analytic continuation, Monodromy theorem, dependence of the analytic continuation on the path (or arc or contour), fixed-end-point or FEP homotopy, homotopic paths, homotopy or deformation of a path into another, function element, centre of convergence, disk of convergence, radius of convergence, Taylor series, continuous dependence of the coefficients and radius of convergence on the path variable for a family of power series defining an analytic continuation on a path, Lipschitz nature of the radius of convergence, continuity is a local property, existence and uniqueness of analytic continuations on paths sufficiently close to a path on which analytic continuation is known to exist

Okay so we continue with the proof of the Monodromy theorem.

**(Refer Slide Time: 01:05)**

Proof of the Monodromy Theorem (Version 1)  
Monodromy Theorem (Version 1) :

Given a homotopy of paths

$F: [a, b] \times [c, d] \rightarrow \mathbb{C}$

$F(\lambda, t) = \gamma_\lambda(t)$  for fixed  $\lambda$

$\forall \lambda \in [c, d], \gamma_\lambda: [a, b] \rightarrow \mathbb{C}$

$\gamma_\lambda(a) = z_0, \gamma_\lambda(b) = z_1$

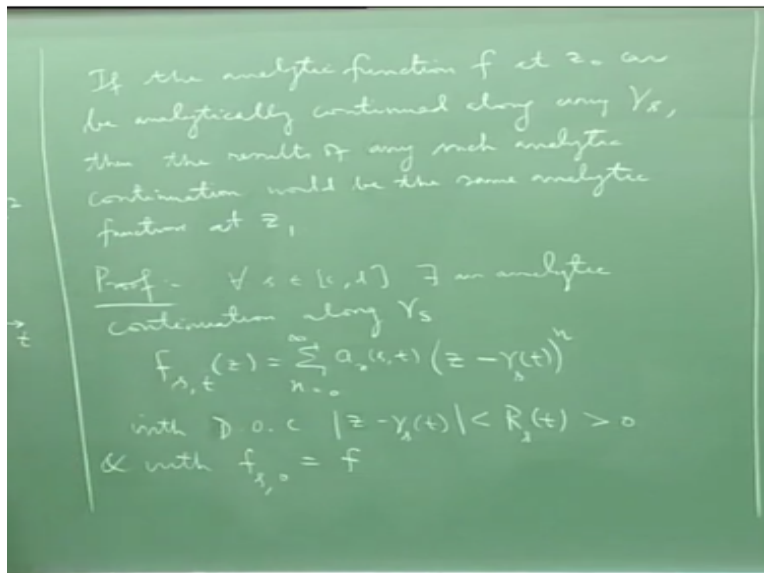

$\gamma_c = \gamma_0, \gamma_d = \gamma_1$

Ok so we have this rectangle which is product of the closed interval  $a, b$  on the real line with the closed interval  $c, d$  on the real line and we have a homotopy capital  $F$  which is the continuous function on this rectangle and it gives homotopy between the path  $\gamma_0$  which is the beginning path in the homotopy and the path  $\gamma_1$  which is the terminal path the homotopy.

And of course any intermediate path in the homotopy is given by  $\gamma_s$  okay,  $\gamma_s$  is just  $f$  of  $s, t$  with  $s$  fixed and  $t$  varying alright and what we need to show is that if we know that there is an analytic function even at the point  $z_0$  which can be analytically continued along each of

these paths. Then analytic continuation of on any path will again lead to the same function at the terminal point  $z_1$ , that is what we have to prove okay, that is the Monodromy theorem.

**(Refer Slide Time: 02:14)**

So, how do we prove this, proof is as (( )) (02:14) so **so** what we will fo is we will do the following thing you know so what is given to me is that there is an analytic continuation of  $f$  along each of these paths okay. So, let me write down some analytic continuation alright.

So, it is so for every  $s$  in  $c, d$  there exist an analytic continuation along the path  $\gamma_s$  which is given by  $f$  of  $s, t$  of  $z$  sigma  $n=0$  to infinity an of  $s, t$  into  $z - \gamma_s(t)$  to the power of  $n$  with radius of convergence with disc of convergence mod  $z - \gamma_s(t)$  is less than  $R_{s,t}$  okay which is of course positive with of course and with  $f$  of  $s, 0=f$  okay.

So, for so what I have done is for each  $\gamma_s$  I have written this  $f$  of  $s, t$  which is an analytic continuation along the path  $\gamma_s$  starting with  $f$  okay. And it has a certain disc of convergence right. So, you know so on this picture  $\gamma_s$  is this path which is the image under capital  $F$  of this line segment okay where  $s$  is fixed and  $c$  I mean  $t$  varies from  $c$  to  $d$ ,  $t$  varies from  $a$  to  $b$ ,  $s$  is fixed value between small  $c$  and small  $d$ .

And  $t$  varies from  $a$  to  $b$  and the image of this line segment under this continuous function  $f$  is this path  $\gamma_s$  and if you give me a point  $t$  here point corresponding to a certain value of  $t$

between  $a$  and  $d$ . Then the corresponding point here in this rectangular have coordinates  $s, t$  and the corresponding point and the image of this point under  $f$  will be  $f$  of  $s, t$  which is  $s \gamma s$  of  $t$ .

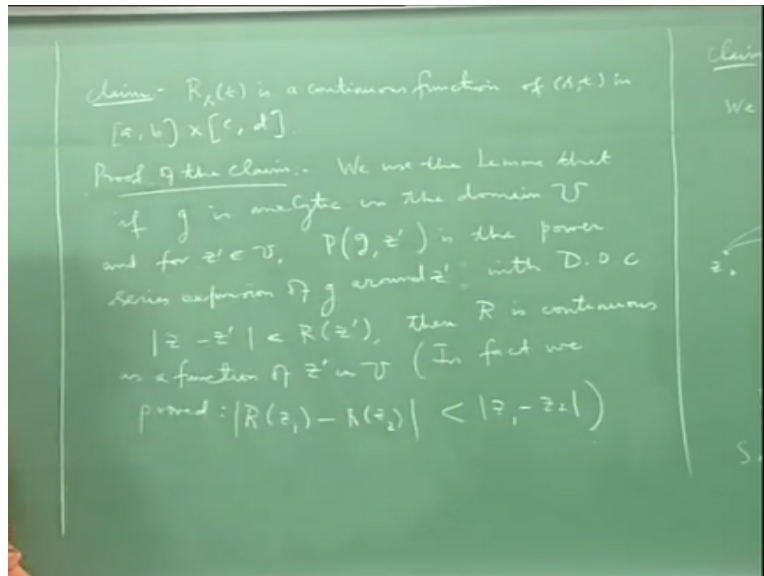

So, it is going to be this point  $\gamma s$  of  $t$  I going to write a point here and I have an analytic continuation along this  $\gamma s$  as  $t$  varies and that this analytic continuation  $f$  is  $t$  okay and at the point  $\gamma s$  of  $t$  I am going to get a power series centred at  $\gamma s$  of  $t$  okay. And the only thing that you have to remember is since there are 2 real variables or everything I mean  $f a, a n$  and  $\gamma$  and also  $R$  they will all depend on 2 real variables  $s$  and  $t$  okay.

So, for the depending only on 1 variable, if you are writing an analytic continuation on the single path then you get only one variable which is the path variable. But now you are writing an analytic continuation on a family of paths okay which means that you have also a variable for different paths which is the variable  $s$ . So, there are 2 variables involved  $s$  and  $t$ .

So, everything is a function of the power series in the analytic continuation the coefficients of the power series the centres of the power series, the radial of convergence of the power series they are all depending on this 2 variables okay. So, less than  $t$  will appear in all of them that is how we write it okay and so this is given to me there is an analytic continuation like this okay, I do not care what this continuation is for the moment alright.

But it is given the there is an analytic continuation, now what I am going to do okay. So, the fact I am going to use is that this function  $R_s$  of  $t$  if you think of it is a function from this rectangle with  $s, t$  as of the variable of the rectangle. Then the claim is this  $R$  is a continuous function of that on that rectangle okay. In fact  $a n$  will also be a continuous function on that rectangle okay.

**(Refer Slide Time: 07:12)**

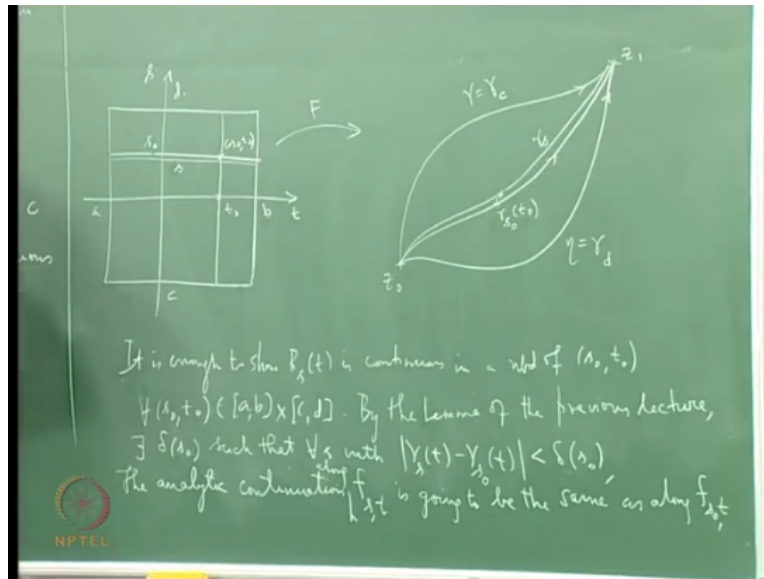

So, here is a claim  $R$  is a continuous function of the point  $s, t$  in the rectangle  $a, b$  cross  $c, d$  it is a continuous function. So, this is the claim we use the lemma that if  $f$  is so if  $g$  is analytic in the domain  $d U$  and for  $z$  in  $U$ ,  $P(g, z)$ , so I will let me put  $z$  prime for  $z$  prime in  $U$ ,  $P(g, z$  prime is the power series expansion of  $g$  around  $z$  prime with disc of convergence mod  $z - z$  prime lesser than  $R$  of  $z$  prime.

Then  $R$  is continuous as a function of  $z$  prime in  $U$ . So, I am I am just using the fact that you know if you have an analytic function on domain and at various point he start writing it is power series expansion okay. So, at various points I will get various power series expansions and at corresponding to each of these power series expansions I am going to get radii of convergence.

So, as a change in the point I am going to get different radii of convergence okay depending on which point I am expanding the function of power series about, then the fact is that this radii as you change the point the radii of convergence will change continuously okay. So, we proved this, so in fact what we proved is in fact we prove we prove if you remember we prove  $R$  of  $z_1 - R$  of  $z_2$  mod is strictly less than mod of  $z_1 - z_2$ , we proved this.

The difference in the radii of convergence of the power series expansion at  $z_1$  and  $z_2$  cannot exceed is smaller than the distance between the 2 points okay. So, this is the fact we need to use, so, let me draw another diagram.

(Refer Slide Time: 10:47)

So, you know the situation is like this, so here is my rectangle so this is a, this is b, this is c, this is d and this is the variable t, this is the variable s okay. And here is my particular value s well if you want you know I can take  $s_0$  and then I can take certain  $t_0$ , so I will get this point which corresponds to  $s_0, t_0$  and I have this f, I have brought this f is going to give me as well it is going to map this segment onto of course gamma which is gamma of a rather gamma c.

This is the path from  $z_0$  to  $z_1$  and then I have this other path below which is neta and neta is gamma d okay. And corresponding to this line segment with y coordinate  $s_0$  I am going to get the intermediate path gamma  $s_0$ , this is gammas of  $s_0$  okay. And this is the point that corresponds to gammas of  $s_0$  of  $t_0$  okay, this is what I am going to get.

Now see I have to show that I am trying to show that  $R_s$  of t is a continuous function of s, t okay to show that a function is continuous it is enough to show it is locally continuous okay. So, it is enough to show that  $R_s$  of t is continuous in s and t in a neighbourhood of each point  $s_0, t_0$  in the rectangle alright. So you know fix so let me write that down it is enough to show  $R_s$  t is continuous in a neighbourhood of  $s_0, t_0$  for every point  $s_0, t_0$  in that rectangle it is enough to show this alright.

Because continuity is a local property to show that a function is continuous it is enough to show that on an open cover okay. So, you know I have those were frozen this  $s_0$  and  $t_0$  okay, now for the moment what you do is you see you just looked at this path  $\gamma_{s_0}$  okay all along this path  $\gamma_{s_0}$ , there is this analytic continuation which is given by  $f_{s_0, t}$  there is an there is this analytic continuation  $f_{s_0, t}$ .

And it starts with  $f_{s_0, 0}$  which is  $f$  it is an analytic continuation of  $f$  along this  $\gamma_{s_0}$  alright. Now you see by the previous lemma okay for all  $t$  for all paths close enough to this path the analytic continuations are the same okay. We have seen the previous lemma that we prove in the preceding lecture was a if you have analytic continuation on the path there along sufficiently closed paths the analytic continuation is going to exist.

And it is going to be and it is going to lead to the same function at the end okay, so what you must understand is on nearby path okay nearby means for  $s$  close to  $s_0$  okay. If you take nearby paths then the analytic continuations are going to be same as the analytic continuation on the path  $\gamma_{s_0}$  okay. So, by the previous by the lemma of the previous lecture namely the lemma that I have proved at the end of the previous lecture .

There exist  $\delta$  of  $s_0$  such that for every  $s$  with  $\text{mod } \gamma_s \text{ of } t - \gamma_{s_0} \text{ of } t$  is less than  $\delta$  of  $s_0$  the analytic continuation  $f_{s, t}$  is going to be the same as analytic continuation along  $f_{s_0, t}$  is going to be the same as along  $f_{s_0, t}$  this is what we, so you know I am saying that you know if you choose any  $s$  which is very close to  $s_0$  okay, see if you choose  $s$  close to  $s_0$  alright.

Then of course the  $\gamma_s$  will come very it will come very close to  $\gamma_{s_0}$ , so this is  $\gamma_s$ , this is  $\gamma_s$  and this is  $\gamma_{s_0}$ . If  $s$  is close to  $s_0$  then  $\gamma_s$  is close to  $\gamma_{s_0}$  that is simply because  $f$  is continuous. And  $\gamma_s$  is the image of this line segment that corresponds to  $s$  and  $\gamma_{s_0}$  is the image of this line segment that corresponds to  $s_0$  okay and nearby continuation function maps nearby objects to nearby objects is just continuity.

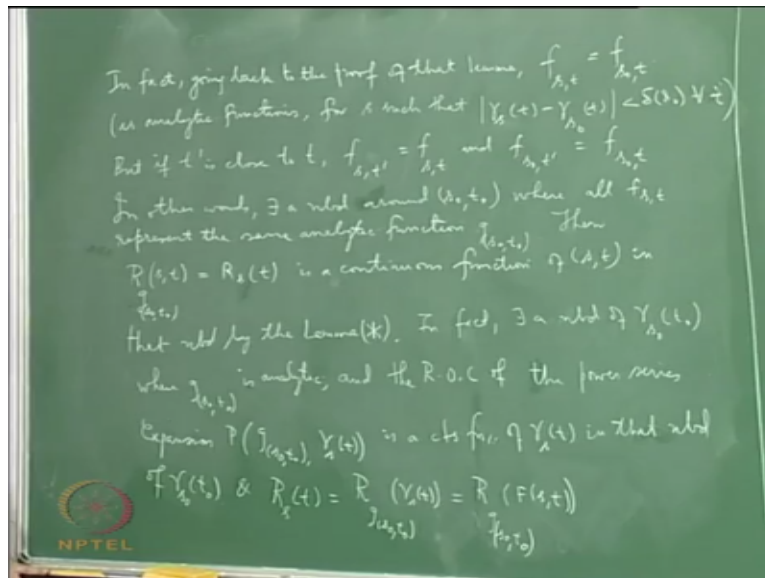

So, as you make  $s$  close to  $s_0$ , the  $\gamma_s$  comes closer to  $\gamma_{s_0}$  but then if you have chosen  $s$ , so that the distance between the point  $\gamma_{st}$  and  $\gamma_{s_0}$  of  $t$  for each  $t$  is always

less than this delta s0 okay. Then the analytic continuation among gamma is the same as the analytic continuation on gamma s0, this is what we prove in the in a lemma in the previous lecture in words to state that we prove to state what we proved was is that if analytic continuation exist along a path.

Then analytic continuation will also exist along sufficiently closed paths and all these analytic continuations will re-lead to the same function at the ending point, I am just using that lemma okay. The only thing is that this delta will now this depends on that path s0, gamma s0 okay. So, I am if I use that, so what I get from this if I use that lemma is that so in fact you know in fact what we if you go back to the proof of that lemma what we proved was that.

The analytic continuation at gamma s of t the analytic function you get at gamma s of t is the same as the analytic function you get the gamma as at a gamma s0 of t okay. Because what we did was we actually defined on a sufficiently closed path we defined an analytic continuation by simply writing out the power series expansion at that point okay. So, in fact the analytic continuation the function you get at s t is literally the same function that you get at s, s0 t for s sufficiently close to s0.

**(Refer Slide Time: 19:54)**

So, let me write this in fact going back to the proof of that lemma function fs t is the same as the function fs0 t as functions for s such that mod gamma s of t-gamma s0 t is less than delta s0 for

all t okay. So, this is again going back to the proof of that lemma alright and so you know so what this tells you is that you know if you take s sufficiently close to s0 alright.

Then you are getting you are all for any value of t, the analytic function you are going to get is the same for a fixed value of t okay all for all these s which is close enough to s0 and for any fixed t the analytic function f\_s t is the same as f\_{s0} t alright. Now what I want it understand is that but you see if t prime is close to t of course f\_s t prime is the same as f\_{s0} t and f\_{s0} t prime is the same as f\_{s0} t that is also true.

That is because is the analytic continuations, analytic continuations require that as the t variable comes close to a particular value then the analytic functions given by the power series also coincide okay. So, what all these tells you is, it tells you that you know it tells you that there is this neighbourhood around s0, t0 where all the functions f\_{st} are a single analytic function okay.

So, in other words there exist a neighbourhood around s0, t0 where all f\_{st} represent the same analytic function okay and call that function as g\_{s0, t0} okay. Then R of R\_{g\_{s0, t0}} of there is radius of convergence of the power series of g\_{s0, t0} at the point s, t is just r\_{st} r\_{s0, t0} of t in our notation is a continuous function of s, t in that neighbourhood by the lemma.

**(Refer Slide Time: 24:37)**

So, you know I will call this is I will lemma star so I will label this lemma star this is this lemma star okay not to be confused with the lemma of the previous lecture okay. This is lemma star is the lemma that if you take an analytic function in a domain then if you expand the analytic function as a power series at each point then the corresponding radii of convergence will be continuous will be a continuous function of the point.

**(Refer Slide Time: 24:57)**

So, you know there is a small neighbourhood here where all the  $f_{s,t}$ 's here all the  $f_{s,t}$ 's represent the same function  $g_{s_0, t_0}$  what it means is if you take the image of this neighbourhood here okay you will because of the continuity of  $f$  I can find a small enough neighbourhood here into which the image of this neighbourhood goes okay.

And for all point in that neighbourhood your you are actually expanding the same function  $g_{s_0, t_0}$  in this neighbourhood which contains that neighbourhood okay, see you take this  $\gamma_{s_0}$  of  $t_0$  which is the image of the point  $s_0, t_0$  under  $f$  okay. Then you take a sufficiently small neighbourhood of  $\gamma_{s_0}$  of  $t_0$  where this  $g_{s_0, t_0}$  come at  $t_0$  live lives, see after all  $g_{s_0, t_0}$  is an analytic function which is it is not defined here,  $g_{s_0, t_0}$  lives here.

So, it is this so this is the point at which  $g_{s_0, t_0}$  is analytic okay,  $g_{s_0, t_0}$  is analytic at this point which is the point  $\gamma_{s_0}$  of  $t_0$  okay, it is analytic there and there  $g_s$  if you in that neighbourhood you take any point and if you write the power series expansion of this  $g_{s_0, t_0}$  at

at that point and look at it is radius of convergence. Then the radius of convergence is a continuous function of the point okay.

So, the radius of convergence of  $g_{s_0, t_0}$  at each point in this neighbourhood surrounding  $\gamma_{s_0, t_0}$  is a continuous function of the point  $\gamma_{s_0, t_0}$ . But  $\gamma_{s_0, t_0}$  is a continuous function of  $s_0, t_0$  because it is actually  $f$ , so  $R$  of  $R_{s_0, t_0}$  becomes a continuous function of  $s_0, t_0$  okay. So, in fact so let me write that properly so to in fact there exist a neighbourhood of  $\gamma_{s_0, t_0}$  where  $g_{s_0, t_0}$  is analytic.

And the radius of convergence of the power series expansion  $P_{g_{s_0, t_0}}$  at  $\gamma_{s_0, t_0}$  is a continuous function of  $\gamma_{s_0, t_0}$  in the in that neighbourhood of  $\gamma_{s_0, t_0}$  okay, this is what I am saying right. And  $R_{s_0, t_0}$  is actually and  $R_{s_0, t_0}$  is actually the radius of convergence of the power expansion of  $g_{s_0, t_0}$  at the  $\gamma_{s_0, t_0}$  which is continuous function.

So, and mind you this is just  $R$  composed with I am here now I am thinking of  $R$  as composed with  $f$  of  $s_0, t_0$ . Because  $f$  of  $s_0, t_0$  is  $\gamma_{s_0, t_0}$  okay. So, it is a composition of  $f$ ,  $f$  is continuous and  $R$  is continuous therefore composition of continuous function, so it is continuous. So, you know  $R$  is indirectly a function of  $s_0, t_0$  so I wrote it directly there but if you want it more explicitly I have written it here okay, this is the reason why  $R$  is a continuous function of  $s_0, t_0$  okay.

So, what I have proved is  $R$  is a continuous function of  $s_0, t_0$  locally okay but that is enough to say that is continuous globally because continuity is a local property right, it is a property that can be verified at each point in an neighbourhood of each point. So, I have proved this claim okay, so I have this claim that  $R_{s_0, t_0}$  is a continuous function of  $s_0, t_0$  in this rectangle okay. Now how do I proceed in the same way I simply take the image of that rectangle and under  $R$  and I notice that the image will again be a compact interval and it will have a minimum and I am going to call that minimum as  $\delta$  okay.

**(Refer Slide Time: 30:30)**

So, you know so  $R_s(t)$  is so this settles the claim that  $R_s(t)$  is continuous in  $s, t$  varying in this rectangle okay. And take the image under  $R$  of this rectangle okay, see this rectangle is anyway compact and connected, the rectangle on the plane is a compact and connected set. Of course it is a connected set because it is actually path connected any 2 points can be join by a path.

In fact even by a straight line if you want okay and so it is connected certainly and it is compact because it is closed and bounded. Because I have taken the closed rectangle, so it is compact and I have a continuous function  $R$  defined on this compact set okay. So, the result will be the image under  $R$  of this compact set will again be a compact subset compact connected subset of the real line.

So, it will again be a closed interval in the real line okay and of course  $R$  is always positive, so I am going to get a closed interval with minimum with left end point greater than 0 okay. So, which will be  $\delta$ ,  $\delta$  with  $\delta$  positive okay, so this is where I use a continuity of  $R$ , I need the continuity of  $R$  to say that the image under  $R$  of this rectangle is you know compact and connected and a compact connected subset of  $R$  is just a closed interval.

And of course these  $R$  are  $R$  refers to various radii of convergence they are all positive radii of convergence. So, the so  $R$  values are always positive never 0 therefore there is going to be a minimum value of  $R$  that is going to be  $\delta$  small  $\delta$ . And there is also going to be a maximum value of that  $R$  that is capital  $\Delta$  okay. Of course you know in all these situations .

I am really not worried about the case when at some point you know you get a power series whose radius of convergence is infinite okay, see you must always remember that see you always see me a writing this small delta, capital delta this capital delta tells you that you know the  $R$  is finite, the radii of convergence is a finite and you know radii of convergence of the radius of convergence is finite means that at the circle of convergence there is a singularity for that analytic function.

Because if there were no singularities the radius of convergence would have would become infinite okay. So, always when the radius of convergence is finite on the circle of convergence there is a singular point for that point, there is a point beyond which you cannot extend that function okay. So, there is a point at which you cannot extend that function, so there is a singularity, so you always see me a writing this delta here capital delta.

And I just wanted to make you this remark that you know, I am never looking at the case when radius of convergence is infinite. Because the radius of convergence is infinite means that one of the functions you are that occur in the analytic continuation is entire if one of the functions is entire then there is nothing to continue because an entire function can be continued everywhere.

So, you know you are not going to get you are going to not going to get anything you are only going to get that function no matter how you analytically continue it okay, it is going to be just direct analytic continuation just extension of that entire function to the whole complex plane. So, there is nothing to prove okay, so all these things become interesting only when the radii of convergence of all finite okay.

The radii of convergence become infinite even for 1 point all these results they become trivial there is nothing there is really no real question there to answer okay. So, that is the reason I am always thinking of  $R$  positive and finite okay, fine. So, now comes the now that I have this delta see now I am in very good shape.

So, you see how I use this  $\delta$  as follows what I do is I have this you see this rectangle that I have  $a, b$  cross  $c, d$  you see I can actually divide this rectangle into by a series of lines parallel lines you know  $s_0, s_1, s_2$  and so on some  $s_k$  and so on. So, that you know well maybe I rather call this line as  $s_0$  that corresponds to  $c$  then I have  $s_1$ , I call this as  $s_2$ , I call this as  $s_3$ .

So, maybe instead of writing it here, I will write it here, this is  $s_1$ , this is  $s_2$ , well and this is  $s_3$  and so on. Then I will end up with  $s_k$  and finally I end up with  $s_N$  well some  $N$  capital  $N$  which is  $d$  alright and of course this value will correspond to  $s_{N-1}$ . So, I can find these  $s$  is in such a way that you know if you take the image of each of these rectangular strips okay, you will get a piece of this homotopy leaf.

There is a piece of this leaf like this region in between these 2 paths, such that you know the distance of the points corresponding to given  $t$  is less than  $\delta$  okay. So, let me write this so let me draw this diagram first, so here is how the diagram is going to look like. So, you know , so this is  $\gamma_{s_0}$  which is just  $\gamma_c$ , this is  $\gamma_{s_1}$  then I will have  $\gamma_{s_2}$  and so on.

Then finally I have this is  $\gamma_{s_N}$  which is just  $\gamma_d$  and this guy here is  $\gamma_{s_{N-1}}$  okay, I can find these values starting from  $s_0$  to  $s_N$  for sufficiently large  $N$ . Such that you know you give me any value of  $t$  then of course the image of something like this will be something like this well if I draw it, it will be something like this okay.

That this will correspond to a given  $t$  alright it will be this point this first end point  $z_0$  when  $t$  is  $a$  and this thing will collapse to the terminal point  $z_1$  when  $t=b$  but in between the image of this line segment will be something like this that will also be a path connecting a point, connecting this the point corresponding to  $t$  in the first path with the point corresponding to  $t$  in the last path okay.

And but the point is that you know if you take any 2 successive points the distance of those points is less than  $\delta$  okay. So, you can find such a finite collection of points okay. So, there exist  $s_0=c$  strictly less than  $s_1$  and so on lesser than  $s_{N-1}=d$  such that for every  $t$  in  $a, b$ . The

distance between  $\gamma_s$  and  $\gamma_{s'}$  is less than  $\delta$  for  $s, s'$  belonging to any sub interval  $[s_i, s_{i+1}]$  of length  $\epsilon$ .

And so on up to  $n-1$  okay. You can divide this rectangle into small thin rectangular strips with this property this is purely by compactness okay. So, is a compactness argument that you can further expand and try to write down. But it is obvious to write down. So, you can do this now once you do this once you realise that you can do this to prove the theorem is over.

Because you see what will happen is you see because the distance between all the paths in between  $\gamma_{s_i}$  and  $\gamma_{s_{i+1}}$  is less than  $\delta$ . They will all define the same analytic continuation okay that again the proof of that is again following the proof of the lemma of the previous lecture. So, what will tell you is that on each for each of these pieces the analytic continuation along the upper path is the same as the analytic continuation on the longer lower path.

And then you go by induction okay so, the analytic continuation along  $\gamma_{s_0}$  is the same as the analytic continuation along  $\gamma_{s_1}$ . The analytic continuation along  $\gamma_{s_1}$  the same as the analytic continuation along  $\gamma_{s_2}$  and by induction finally you get that the analytic continuation along  $\gamma_{s_0}$  is the same as the analytic continuation along  $\gamma_{s_n}$ .

In other words the analytic continuation along  $\gamma_c$  which is  $\gamma$  is the same as the analytic continuation along  $\gamma_d$  which is  $\eta$  okay. And that proves the monodromy theorem okay. So, what you must understand is that it is a kind of a cleverly playing upon the ideas of the lemma that we proved in the previous theorem and also critically using the fact that the radius of convergence is a continuous function.

That is a very critical fact that keeps using and also let me again repeat the main idea in the proof of the lemma of the previous lecture was that you know if you take sufficiently closed paths then there is only there is a unique analytic continuation on that path and it is simply defined by

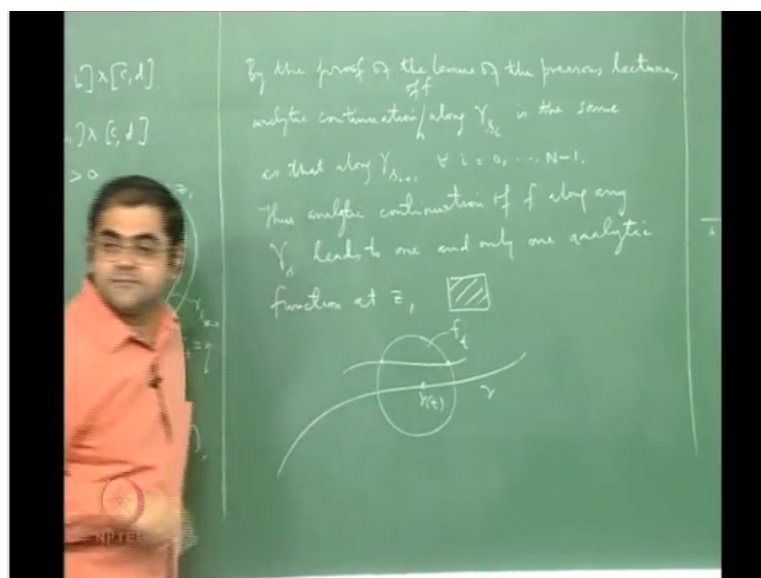

expanding the if the relevant function on the given path into a power series okay. So, if you **you** take to nearby paths.

And if I have this analytic continuation along the path  $\gamma_0$  on along a nearby path  $\gamma_1$  is the analytic continuation how is the defined it is very simple what you do is you simply defined the analytic continuation by simply expanding this function at  $\gamma_0$  of  $t_0$  at  $\gamma_1$  of  $t_0$ . And you do this for every  $t_0$  okay, so the fact the whole idea is you know if a function is analytic at a point it leaves a neighbourhood.

And therefore that function itself can be used to define power series in paths in that neighbourhood okay. So, it in other words if you have a path and you give me a point on the path and you give me a analytic function on that point. Then there is a disc by definition of analyticity there is a disc where the function is analytic and whenever there is any other path which passes through the disc along the portion of the path which passes through the disc.

I can simply defined the analytic continuation to be the power series expansion of this function that leaves okay. And that is the crucial this is very very crucial idea okay so, that is the crucial idea that is being used and also the idea that the radius of convergence is a continuous function of the point okay.

**(Refer Slide Time: 44:39)**

So, let me write down by the proof of the lemma of the previous lecture analytic continuation along  $\gamma_{s_i}$  is the same as that along analytic continuation of  $f$  along  $\gamma_{s_i}$  is the same as that along  $\gamma_{s_{i+1}}$  for every  $i$  starting from 0 to  $N-1$  thus analytic continuation of  $f$  along any  $\gamma_s$  leads to one and only one function at  $z_1$  and that is the proof of the monodromy theorem.

So, let me again at the risk of reputation let me against us the whole idea is if you have a path and at a point  $z_0$  if you have if you are given a analytic function  $f_{s_0}$  I mean  $f_{z_0}$  an analytic function here. Then if you have any other path which hits this disc where  $f_{z_0}$  lives along this path along the portion of the path from here if here leaving out the end points there is this  $f$  itself has a trivial analytic continuation along this.

That is the whole idea that is being used again integrate and you are of course crucially using very very crucially the fact that the analytic continuation along a path is unique once you fix a parameterisation of the path the analytic continuation is unique for a given starting function okay. You cannot have two different analytic continuations with the same starting function for the same parameterise path that is one important fact.

The other important fact is the radius of convergence that varies continuously as the it is the continuously variable of the point where you are expanding or writing the power series about okay. So, these are crucial facts so, I will stop here.
