**Goals of Lecture 33:**

\*\* In the previous lecture, we proved the various versions of the Maximum principle and introduced Schwarz's lemma which says that the only conformal automorphisms of the unit disc fixing the origin are rotations and non-rotations are contractive.

In this lecture, we prove Schwarz's lemma using the Maximum principle

(Refer Slide Time: 00:26)

**Goals of Lecture 33:**

\*\*\* This lecture discusses the ideas behind the Riemann Mapping theorem and uses Schwarz's lemma to show the uniqueness for Riemann mappings of a proper simply-connected domain with predetermined function value and derivative at a fixed point of the domain

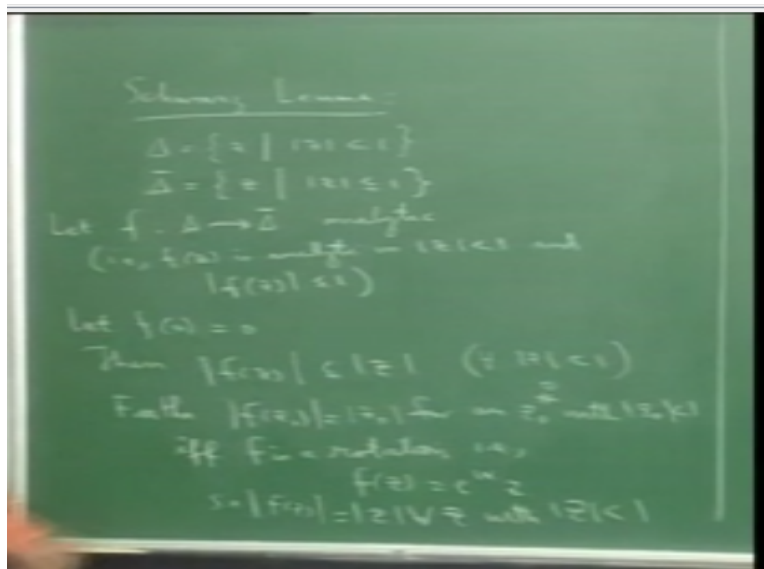

\*\*\*\* This lecture discusses the initial step towards showing the existence of a Riemann Mapping

(Refer Slide Time: 00:34)

**Keywords for Lecture 33:**

interior point, continuous extension of a function to the boundary, maximum attained on the boundary, Laplacian operator on a domain in the complex plane, Harmonic function, infinitely real differentiable or  $C^\infty$  function, real analytic function, real and imaginary parts of an analytic function are harmonic, existence of harmonic conjugate for a harmonic function on a simply connected domain, existence of analytic function whose real part is a given harmonic function on a simply connected domain, integrating with respect to the modulus of the differential, arc length, mean value of an integral, mean value as a function of radial distance, continuity of the mean-value function, harmonicity equivalent to Mean-Value property for continuous functions, modulus of the integral is bounded by integral of the modulus, continuity is uniform on compact subsets, Cauchy Integral formula, upper bound, strict upper bound, attained upper bound, Strict Maximum principle, Maximum Modulus principle, Schwarz's Lemma, contraction mapping, unit disc, rotation, conformal automorphism or holomorphic self-isomorphism, bilinear transformation or Moebius transformation or linear fractional transformation, Riemann's Removable Singularity theorem, the sum of a convergent power series is analytic with Taylor expansion the same series, Riemann Mapping theorem, holomorphic isomorphism of domains in the complex plane, holomorphic isomorphism class, Riemann mapping defined on a domain, simply-connected domain, existence of analytic branch of logarithm and of square root for never-vanishing analytic functions on a simply-connected domain

(Refer Slide Time: 00:47)

Alright, so what we are discussing is a short Schwarz lemma where we are looking at a function  $f$  which is defined on the unit disc and it is taking values in the closure of the unit disc okay. And we assume that maps  $0$  to  $0$  okay then the Schwarz lemma says that if you take any complex number in  $z$  in the unit disc. Then the modulus of its image cannot exceed the modulus of the complex number okay.

So, and the fact is that you get equality even at  $1$  value if and if it is a rotation okay. And in which case you get equality everywhere okay and of course you know rotation is bilinear transformation and it will map the unit disc isomorphically onto the unit disc and it fixes the

origin and corollary to Schwarz lemma is that every automorphism of the unit disc every holomorphic self map of the unit disc onto itself which is an isomorphism namely which has an inverse which is also holomorphic. And which fixes the origin has to be a rotation okay so, now so, let us try to prove these things.

**(Refer Slide Time: 02:22)**

so, the first thing is so, let me Schwarz lemma so, the idea of the proof is very easy actually you just going to apply the maximum principle and nothing else okay. So, what you do is put  $g$  of  $z$  is equal to  $fz$  by  $z$  okay put  $g$  of  $z$  is equal to  $fz$  by  $z$  for  $z \neq 0$  okay. Because I am dividing by  $z$  I should put  $z \neq 0$  then but the beautiful thing is that of course  $g$  is analytic on the punctured unit disc namely if  $z$  is not zero.

Then  $fz$  by  $z$  is also analytic because numerator is  $fz$  which is analytic denominator is  $z$  which is analytic and you know the quotient of analytic function is analytic wherever the denominator does not vanish okay. Therefore this  $g$  as I have defined is it as I have defined it is analytic on the punctured unit disc. But the fact is it is even analytic at the origin the reason is because  $f$  of  $0$  equal to  $0$  okay.

So, you see  $f$  of  $z$  if you write the power series of  $f$  of  $z$  centred at  $0$  namely the Taylor expansion of  $f$  of  $z$  okay. So, what will you get the Taylor expansion of  $f$  of  $z$  at  $z$  equal to  $0$  which is a you know classically call  $(0)$  (03:56) expansion the Taylor expansion at zeroes called the machloren

expansion. So, the Maclaurin expansion is what it is just  $f(z)$  is equal to you know  $f'(0)z + \frac{f''(0)}{2!}z^2 + \dots$

This is what it is use the Taylor expansion but what if  $f'(0) = 0$  because  $f$  is supposed to fix the origin it maps 0 to 0. So, what I will get this I will get  $\frac{f''(0)}{2!}z^2 + \dots$  where  $h(z)$  is analytic on  $\Delta$  on the unit disc why is  $h(z)$  analytic because you know  $h(z)$  will have this power series expansion that is gotten by taking this power series expansion.

And you divide it by  $z$  okay namely  $h(z)$  will be  $\frac{f''(0)}{2!}z + \dots$  and so on and that will be a convergent power series okay so,  $h(z)$  is given by convergent power series the origin so, it is analytic at the origin alright. But on the other hand outside the origin  $h(z)$  is actually  $f(z)/z$  okay so, what you have saying this function  $g(z)$  extends to an analytic function  $h(z)$  the origin.

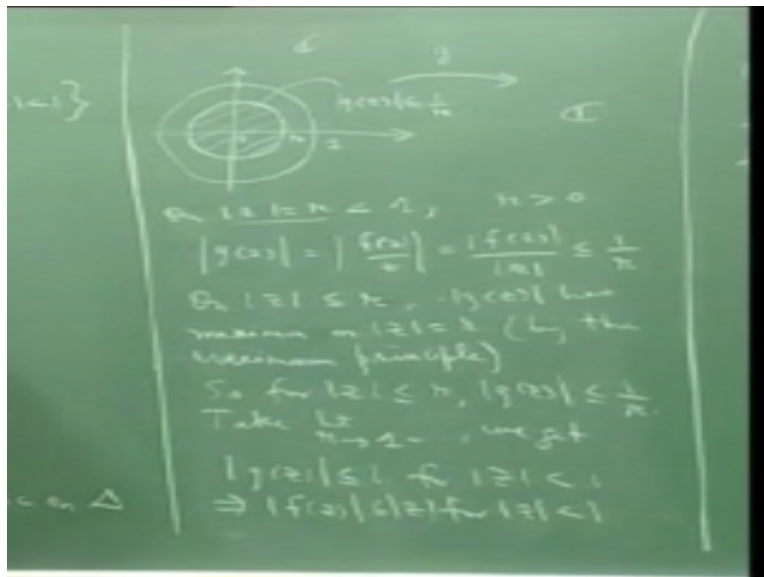

In other words  $g(z)$  itself is an analytic function in the at the origin okay. So, as  $h(z)$  is equal to  $g(z)$  or  $z \neq 0$  this shows that actually 0 is a removable singularity for  $g(z)$  okay see  $g(z)$  is like  $\frac{\sin z}{z}$  which a priori cannot be defined at  $z = 0$ . Because  $z$  in the denominator but actually if you write it as a power series  $\frac{\sin z}{z}$  is also defined at  $z = 0$ .

Because at 0 it has a limit it has a finite limit so, remarks the removable singularities theorem says that if you have if a function at a point where it is not defined but suppose it is a function which is analytic and delete neighbourhood of a point okay. Then it can be extended to analytic function at that point if one of the following three conditions satisfy or satisfied is satisfied namely the first condition is that  $f(z)$  tends to limit as you tend to that point.

The second condition is that if the function is bounded in a deleted neighbourhood of that point and of course the third thing is if the function has the function can be extended it has a power series expansion at that point okay. And in fact all the three are happening here okay so,  $g(z)$  is analytic on a whole unit disc. So, you know I will keep writing  $f(z)$  by  $h(z)$  I mean I simply write  $g(z)$

is equal to  $fz$  by  $z$  and just remember that this is the expression for  $g$  when  $z$  is not equal to 0. When  $z$  is equal to 0 it is actually  $h$  okay and  $h$  is actually the power series expansion of  $g$  at the origin at and the origin is removable singularities.

(Refer Slide Time: 08:13)

So, it is a point to which  $g$  can be extended analytic okay so, well fine so, after that remark what we do next is now we are in a position to apply maximum principle okay. So, what will you do is the following thing. So, what I going to do is you going to take this unit disc and so, I have this function  $g$  which going from unit disc what I am going to, I am going to take circle centred at the origin radius small  $r$  okay.

So, and I am going to look the function  $g$  of  $z$  which is  $fz$  by  $z$  alright. And I am going to look at what it is modulus is on the circle okay. So, on  $|z|=r$  which is less than 1 okay, so I am looking at all points on a circle centred at the origin radius 1, radius  $r$  small  $r$  where  $r$  is fraction okay what is mood  $gz$ ,  $mod\ gz$  is  $mod\ fz$  by  $z$  because  $mod\ z=r$  and  $r$  is positive okay. so, certainly  $z$  is not 0 and  $g$  has a expression  $f$  of  $z$  by  $z$  when  $z$  is not 0.

And if I calculate  $mod\ g$  I am going to get  $mod\ fz$   $mod\ z$  and that is well that is less than or equal to  $1$  by  $r$ . Because  $mod\ fz$  is always less than or equal to  $1$  is something that is given to me that is just analytic expression for the geometric fact that  $f$  takes values in the closed unit disc okay. And  $mod\ z$  you see  $mod\ z=r$  is already assumed because I am summing the **val**  $mod\ gz$  on the circle

where  $\text{mod } z=r$ , so I get this. If you take  $\text{mod } z$  less than or equal to  $r$   $\text{mod } z$  less than or equal to  $r$ .

If you take this closed disc centred at 0 radius  $r$  including the boundary okay and if you look at the function  $g(z)$  it is analytic there okay. The maximum principle will tell you that its modulus will be maximum on the boundary, so here is where I am applying the maximum principle. So, on  $\text{mod } z$  less than or equal to  $r$   $\text{mod } g(z)$  has maximum on  $\text{mod } z=r$  okay but on  $\text{mod } z=r$   $\text{mod } g(z)$  is less than or equal to  $1/r$ .

And therefore maximum principle will tell you that on this whole disc  $\text{mod } g(z)$  is less than or equal to  $1/r$ , so the upshot on this whole closed disc on here what you are getting is  $\text{mod } g(z)$  I mean see the point is you make an estimate of  $\text{mod } g(z)$  on the boundary of that closed disc which is  $\text{mod } z=r$  and that will also be an upper bound for the values inside because this is the maximum principle.

The maximum principle tells you that the modulus will attain maximum only on the boundary, so if you know a bound for the function on the boundary that bound will also be a bound for the function values on the interior. And of course the function in this case is the modulus of the analytic function okay. So, by the maximum principle okay you know when in applying the maximum principle I am using the fact that you see  $g$  is analytic.

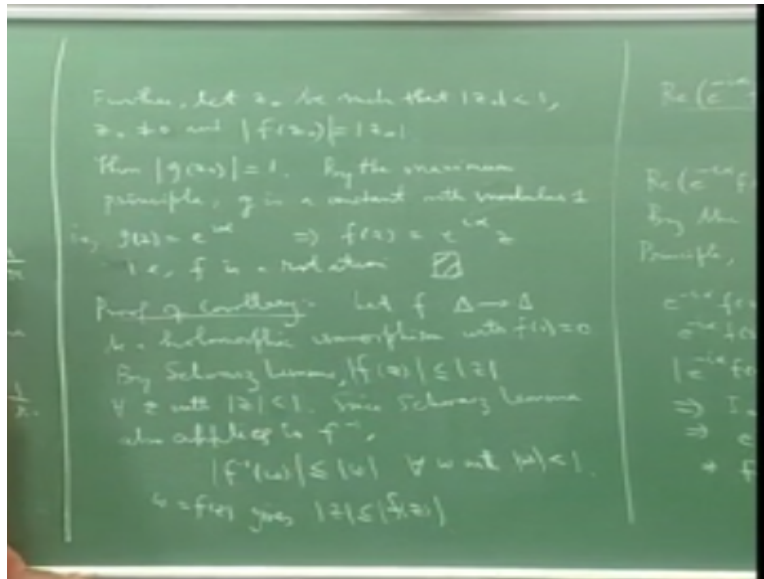

And therefore harmonic because  $g$  is analytic means that both its real and imaginary parts are harmonic and therefore  $g$  is also harmonic and I am using the maximum principle for harmonic functions okay. So, it applies to  $g$ , so  $\text{mod } g$  has a maximum of  $\text{mod } z=r$  but on  $\text{mod } z=r$  it is bounded by  $1/r$  therefore  $1/r$  is a bound for  $g$  on the whole closed disc okay. So, for  $\text{mod } z$  less than or equal to  $r$   $\text{mod } g(z)$  is less than or equal to  $1/r$ , this is what you get.

Now what you do is that you take the limit as  $r$  tends to  $1^-$  okay, if you take the limit as  $r$  tends to  $1^-$  we get  $\text{mod } g(z)$  is strictly less than  $1$  for  $\text{mod } z$  less than  $1$  okay. So, and  $\text{mod } g(z)$  less than or equal to  $1$  will tell you that  $\text{mod } f(z)$  by  $z$  is less than or equal to  $1$  and

that translates to  $\text{mod } fz$  less than or equal to  $z$  for  $\text{mod } z$  less than 1 which is the first assertion in this short lemma okay.

So, so this implies so you get this of course you know there is a little bit of trouble at  $z=0$  but at  $z=0$  this holds because  $\text{mod } f \text{ mod } f_0$  is 0 and of course here I have to put  $\text{mod}$ ,  $\text{mod } f_0$  is 0 which is equal to  $\text{mod } 0$ .

**(Refer Slide Time: 14:02)**

Further let  $z_0$  be such that  $\text{mod } z_0$  less than 1 I will of course need  $f$  is at  $z_0$  not equal to 0 and  $\text{mod of } f \text{ of } z_0 = \text{mod } z_0$  okay. So, in this statement I should correct myself, so  $z_0$  should be non 0 okay because if I do not put that condition then this is always true for  $z_0=0$  okay, so  $z_0$  should be non 0. So, suppose there is an  $z_0$  which is not 0 where  $\text{mod } f z_0 = \text{mod } z_0$  okay.

So, then what you are going to get is that you are going to get then  $\text{mod } gz_0$  is going to be equal to 1 okay. Because after all  $z_0$  is non 0, so  $\text{mod } g$  I mean  $gz_0$  is just  $fz_0$  by  $z_0$  and  $\text{mod } gz_0$  will be  $\text{mod } fz_0$  by  $\text{mod } z_0$  and that will be 1 okay but then again you apply the maximum principle to  $\text{mod } g$  okay, that will tell you that  $\text{mod } g$  will always be it will tell you that  $g$  has to be constant okay.

So, because  $g$  can attain its maximum only on the boundary of the unit disc it provided it extends to boundary of the unit disc. If it does not extend to the boundary of the unit disc it can

never attain the maximum, so whereas  $g$  is bounded by 1. So, the maximum value 1 cannot be attained in the interior if it is attained in the interior then  $g$  has to be a constant, this is the maximum principle okay.

So, so by the maximum principle  $g$  is a constant, so and with  $g$  is constant and  $\text{mod } g \neq 0$  constant with modulus 1 okay. so I will get  $g$  of  $z = e^{i\alpha}$  because a constant a complex number with constant modulus 1 has to be the form  $e^{i\alpha}$  and that means that because  $g$  is  $f$  of  $z$  by  $z$  it will tell you that  $f$  of  $z$  is just  $e^{i\alpha}$  of  $z$ , so it is a rotation okay.

So, that finishes the proof of the short lemma okay, that finishes the proof of the short lemma and I must again point out that I admit earlier the mistake of not saying that  $z \neq 0$  okay, that is important. Because if I did not say that then I already have  $f(0) = 0 = \text{mod } 0$  right. So, so this is the proof of the short lemma I mean what the what you must understand is that the moment  $f$  is a rotation then  $f$  becomes a bilinear transformation.

Therefore it is 1 to 1 also it becomes the conformal isomorphism okay, so what it what your short lemma actually says is that if you take an analytic function from the unit disc into the unit disc the closure of the unit disc which takes the origin to the origin. Then either it is strict contraction in terms of length okay that is  $\text{mod } f(z)$  is strictly less than  $\text{mod } z$  for all  $z$  with  $\text{mod } z$  less than 1 or it is a rotation okay.

So, let us look at this corollary, let us try to prove this corollary, proof of corollary . So, what I will have to do is, I will have to take a holomorphic automorphism of this with fixes the origin and I have to say that it is a rotation. So, let  $f$  from  $\Delta$  to  $\Delta$  the a holomorphic that is analytic isomorphism such with  $f(0) = 0$  okay, so you take a holomorphic isomorphism self isomorphism of the unit disc right.

Now of course to  $f$  I can apply short lemma because conditions of short lemma is that  $f$  should be analytic on the unit disc, it should take values inside the closed unit disc. In this case if taking values in the unit disc itself and it is defined on the unit disc and it takes 0 to 0. So, all the

conditions short lemma satisfied, so I can apply short lemma and I will get by short lemma  $|f(z)|$  is less than or equal to  $|z|$  for all  $z$  with  $|z|$  strictly less than 1, I will get this by applying short lemma to  $f$ .

But mind you what is given is that  $f$  is a holomorphic isomorphism which means  $f$  inverse is also like  $f$ ,  $f$  inverse is also a holomorphic map from  $\Delta$  to  $\Delta$ . And  $f$  inverse will also take 0 to 0 because  $f$  of 0 is 0,  $f$  inverse 0 will also be 0, so I can also apply short lemma to  $f$  inverse okay. since short lemma also applies to  $f$  inverse  $|f^{-1}(w)|$  is less than or equal to  $|w|$  for all  $w$  with  $|w|$  less than  $\rho$ , I can apply short lemma to  $f$  inverse which is the inverse of  $f$  which is given to me to exist.

Because  $f$  is given to be a holomorphic isomorphism which means  $f$  has an inverse and that inverse is also holomorphic okay. But then you put  $w=fz$  in this will give you that  $|z|$  is less than or equal to  $|fz|$  okay and then you compare these 2 opposite inequalities  $|fz|$  less than or equal to  $|z|$ ,  $|z|$  less than or equal to  $|fz|$  and you will get  $|fz|=|z|$  okay and that is it that should tell you that that  $f$  is a rotation.

**(Refer Slide Time: 21:56)**

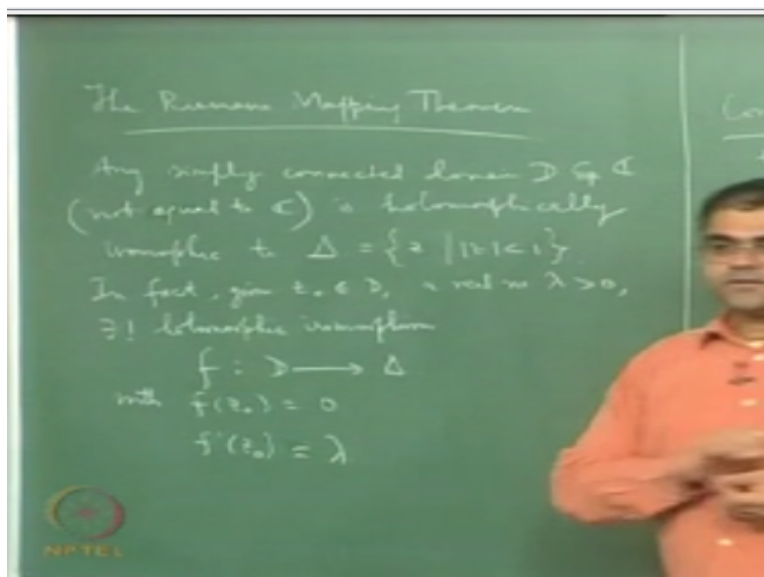

So,  $|fz|=|z|$  for all  $z$  with  $|z|$  less than 1 but we have already seen the proof of the short lemma that whenever  $|fz|=|z|$  holds for a single  $z_0$  different from the origin, then  $f$  has to be a rotation. So, here it is what you are getting is that it holds for all the points on the

unit disc okay, you have more than what you need okay. So, this will imply again by short lemma that  $f$  is a rotation.

So, that proves the fact, that proves the corollary which is that the only holomorphic automorphism of the unit disc that fix the origin they are all rotations okay fine. So, having done this what I am going to embark a is to go into discussion of the Riemann mapping theorem which is something that I want to whose proof which is **is** what I would like to discuss in the coming lectures, it is a very deep theorem.

And it **it** the proof is not easy, it involves several facts and so but to make a preliminary discussion about it, I wanted this fact about automorphism to the unit disc. So let me start with a Riemann mapping theorem which is what our long term goal in the next few lectures is the proof of the Riemann mapping theorem okay.

**(Refer Slide Time: 23:51)**

So, the Riemann mapping theorem okay, so this is a theorem which says that you take any domain in the complex plane which is simply connected and assume that it is not the whole complex plane. Then that domain can be mapped by a holomorphic isomorphism onto the unit disc, so in other words if you take simply connected domains in the complex plane and you go modulo holomorphic isomorphism you will get only a set contained in 2 elements, 1 will be the isomorphism class of the whole complex plane.

And the other will be the isomorphism class of the unit disc and mind you the unit disc is isomorphic to the upper half plane. In fact it is any disc is any disc is any open disc is holomorphic isomorphic into any open half plane because you can always a Mobius transformation that will map the interior of a disc to any half plane okay. So, geometrically up to holomorphic isomorphism unit disc is same as a half plane, any disc is like the unit disc alright any finite disc, it looks like a half plane that is 1 holomorphic isomorphism class.

The other holomorphic isomorphism class is a isomorphism class of the whole complex plane and these are the only 2 holomorphic isomorphism classes of a simply connected domains in the complex on the complex plane okay and that is the statement of the Riemann mapping theorem. So, **so** let me state that any simply connected domain  $D$  not equal to  $\mathbb{C}$ , so I am writing it also in words, I also put it in symbols  $D$  simply connected.

So, the proper domain in the complex plane is holomorphically isomorphic to the unit disc okay. So, this is the celebrated famous Riemann mapping theorem right and so in other words what you are saying is that if you give me a simply connected domain which is different from the complex numbers. Then there is a holomorphic isomorphism from  $D$  to  $\Delta$  which is the unit disc okay.

And that holomorphic isomorphism can be made in fact unique in the following way, so let me explain that in fact given  $z_0$  point  $D$  a real number  $\lambda$  greater than 0 there exist a unique holomorphic is the same as analytic or conformal isomorphism  $f$  from  $D$  to  $\Delta$  with  $f$  of  $z_0=0$ ,  $f'$  of  $z_0=\lambda$ . So, the Riemann mapping theorem says that any simply connected domain which is not the whole complex plane can be holomorphically mapped onto the unit disc.

And you can make that mapping unique if you fix a require that a point of  $D$ , a fixed point of  $D$  goes to the origin under this map and also that at that point the derivative of the map at that point is a fixed real number okay. These conditions make the map  $f$  unique okay and it is so you know there are 2 parts to this 1 part is to find a map okay, then which is rather the hard part.

The easier part is to say that once you have a map  $f$  like this, it is unique and it is the uniqueness part that will use short lemma okay or the corollary of short lemma. So, what I will do is I will first try to apply short lemma which we have just seen to show that you know if a map like that exist it is unique such a map like that is called is given a special name it is called Riemann map, it is called a Riemann map of the domain  $D$  okay.

And the Riemann map is unique if you fix the value of a point on the domain and the derivative of a map at that point okay I of course you I have fixed the value of the point  $z_0$  to be 0 for convenience and most people are in several text books you would see that  $\lambda$  is taken to be equal to 1 okay. But in principle you could take  $\lambda$  to be any positive real value okay.

**(Refer Slide Time: 29:51)**

Now so let us **let us** first prove uniqueness okay, suppose  $f_1$  and  $f_2$ ,  $f_1, f_2$  are from  $D$  to  $\Delta$  or holomorphic isomorphism with these  $f_1$  of  $z$  is 0 which is also equal to  $f_2$  of  $z_0$  and derivative of  $f_1$  at  $z_0$  is the given  $\lambda$  which is equal to the derivative of  $f_2$  at  $z_0$ . I just want to show that  $f_1$  and  $f_2$  are one and the same map right. So, what I do is that I compose  $f_1$  with one of the  $f_2$  with the inverse of the other.

And realise that I get a conformal automorphism of the unit disc which by Schwarz lemma is a rotation. Because it will fix the origin okay so, you see so, the situation is like this so, I have  $D$ , I have  $\Delta$ , I have  $f_1$  then I have  $f_2$  then I have  $\Delta$  here okay. So, if I go like this I will get the

map which is  $f_2$  inverse followed by  $f_1$  okay. And this  $f_2$  inverse followed by  $f_1$  what is the property of this map.

This is holomorphic it is a holomorphic map it is a holomorphic isomorphism because it is a composition of two holomorphic isomorphism  $f_1$  is a holomorphic isomorphism and  $f_2$  is a holomorphic isomorphism therefore  $f_2$  inverse is also the holomorphic isomorphism. The inverse of a holomorphic the inverse of an isomorphism is always an isomorphism okay. So, this is an composition of isomorphism.

Therefore this is also an isomorphism and so, this is an isomorphism is a holomorphic isomorphism. And where does 0 go to 0 goes to 0. Because you see  $z_0$  under this map goes to 0 and under this map also goes to 0. So, if I composite I will get 0 goes to 0 alright so, it is a holomorphic isomorphism from  $\Delta$  to  $\Delta$  which fixes the origin and as we have seen just now seen as a corollary of Schwarz lemma .

This has to be a rotation okay so, by corollary to Schwarz lemma  $f_1 \circ f_2^{-1}$  or  $w$  is equal to  $e^{i\alpha}$  it has to be a rotation of course whenever I write  $e^{i\alpha}$  of course I assuming  $\alpha$  is real okay. Because if I write  $e^{i\alpha}$  with  $\alpha$  complex when it is no longer a rotation a whenever I have write  $e^{i\alpha}$  I am always assuming  $\alpha$  is real.

So, so, this is because of the corollary to Schwarz lemma okay and you see you know if I calculate  $f_1 \circ f_2^{-1}$  so, if I take the derivative of this okay. If I take the derivative of this what I will get is that I will get  $f_1 \circ f_2^{-1}$  derivative at  $w$  is equal to derivative of  $e^{i\alpha}$  at  $w$  which is  $e^{i\alpha}$  okay. The derivative with respect to  $w$  of  $e^{i\alpha}$  is just  $e^{i\alpha}$  okay.

And on this side I will get derivative of this expression but then for this you apply the chain rule okay so, what you will get is you will get  $f_1 \circ f_2^{-1}$  derivative of  $w$  into  $f_2^{-1}$  derivative of  $w$  is equal to the  $i\alpha$  okay. This is just applying the chain rule of differentiation alright and mind you in particular you know I can put any value for  $w$  here.

So, because it is an identity for all  $w$  so, I can put  $w$  equal to 0 okay and what I will get, I will get  $f_1$  dash of  $f_2$  inverse of 0 times  $f_2$  inverse dash of 0 is  $e$  to the  $\alpha$  this is what I will get okay. But then you have to remember that  $f_2$  inverse of 0 is actually  $z_0$  because  $f_2$  of  $z_0$  is 0 okay.

**(Refer Slide Time: 35:22)**

And therefore the so, what will you get is you will get  $f_1$  dash of  $z_0$  right into  $f_2$  inverse derivative at 0 is  $e$  to the  $\alpha$  okay. Now you see  $f_1$  dash  $z_0$  is given to be  $\lambda$  so, I will get  $\lambda$  and the fact is so, let me write that separately okay. Now I claim that  $f_2$  inverse derivative at 0 is also is equal to  $1$  by  $\lambda$  okay that is just because again chain rule applied to  $f_2$  and  $f_2$  inverse okay.

So,  $f_2$  circle  $f_2$  inverse of  $w$  is  $w$  okay and if I apply the chain rule you will get  $f_2$  dash of  $f_2$  inverse of  $w$  times  $f_2$  inverse dash  $w$  is equal to 1 okay. You put  $w$  equal to 0 and you will get  $f_2$  dash of  $z_0$  into  $f_2$  inverse dash of 0 is equal to 1. And this will tell you that  $f_2$  inverse dash of 0 is  $1$  by  $\lambda$  okay mind you  $\lambda$  is a non-zero it is positive.

And therefore you know well if you look at both what will you get is that you will get  $e$  to the  $\alpha$  is equal to 1 okay. And  $1$   $e$  to the  $\alpha$  is 1 you will get  $f_2$   $f_1$  circle inverse  $w$  is equal to  $w$  and this will actually tell you that  $f_1$  equal to  $f_2$  okay. So, that, so by using the Schwarz lemma

are a rather the corollary of the Schwarz lemma namely that every automorphism of the unit disc, that fixes the origin is a rotation.

You are able to show that a Riemann map if it exist which is specified at a point of the domain simply connected to domain which is not equal to the complex plane. And it is if it is images specified at one point and it is derivative at that point is specified then the map is unique. The uniqueness comes from Schwarz lemma actually okay now this is a easier path this is the uniqueness of this Riemann surface.

But now you have to prove the existence of the Riemann map okay you have to show that there is a map from the given simply connected domain which is not the whole complex plane to the unit disc okay. So, let me recall the fact that the domain is simply connected is by definition it means that the any two any curve any path in the domain starting at any point can be continuously shrunk to a point to that point.

That means that there are no holes in that domain okay if you think of it as in terms of the region that in that is enclosed by any closed curve in the domain. Then you do not want any holes there the domain should not contain any holes okay. Because if there is a hole then you cannot continuously shrink a closed curve to a point okay fine so, it is very very important that you have simple connectedness.

So, the question is how do I produce a holomorphic map from to this domain to the unit disc okay which is an isomorphism. So, first step is you try to get hold of some holomorphic map which maps the domain into a sub domain of the unit disc okay. So, let me explain to you the first step towards the proof of the Riemann mapping theorem namely the first step towards the proof of the existence of the Riemann map.

The first step what you do is you show that the domain  $D$  can be conformably that is isomorphically it can be mapped in onto a sub domain of the unit disc first of all you do that. Then you modify that map so, that it can feel out the whole unit disc okay. And I am saying it

loosely modify means it is not just modify. You will have to do a lot of things okay first of all given any simply connected domain how do I land at least into the unit disc.

So, the beautiful point here is the existence of a logarithm for a non-vanishing holomorphic function on a simply connected domain that is essentially used. So, **so** let me explain that.

**(Refer Slide Time: 41:05)**

So, what I am going to do is step1 so, this is a existence of the Riemann map so, I am going on with step1 find holomorphic isomorphism h from D to h of D which is a subset of the unit disc okay. So, the first step is to map first of all D into holomorphically isomorphically into a sub domain of the unit disc. So, what do you what we do is the following thing so, **so** here we exploit all the we exploit the fact that.

The domain is not the whole complex plane and the fact that the domain is simply connected okay so, what we do is since the domain is not the whole complex plane there exist eta not the complex number which is in which is outside the domain okay. I can find such a complex number because it is not the domain is not the whole complex plane. So, that is something outside the domain which is in the complex plane okay.

You take this we have now the next thing is I am going to use of the fact that this domain is simply connected okay. The function  $z - g$  of  $z$  is equal to  $z - \eta$  not is non-vanishing on D that is

obvious because  $z$  because the point  $\eta$  is not in  $D$ . So,  $z - \eta \neq 0$  which  $z$  varying in  $D$  can never be 0 okay. And since it is a non-vanishing function and it is of course analytic okay.

It is analytic function after all it is a translation it is translation by  $-\eta$  not okay so, it is an analytic function this analytic function is non-vanishing on this domain  $D$  which is simply connected therefore it has a logarithm okay since  $D$  is simply connected we have an analytic branch of  $\log z - \eta$  not on  $D$  okay. And therefore the movement I have  $\log z - \eta$  not I will have an analytic branch of the square root of  $z - \eta$  not on  $D$ .

And my claim is that function will do the job of mapping  $D$  I can use that function carefully to map  $D$  onto a sub domain of the unit disc okay. So, let me write that and then we have an analytic branch of root of  $z - \eta$  not as exponentially of half  $\log z - \eta$  not on  $D$  we can use this branch of root of  $z - \eta$  not to get the holomorphic isomorphism okay. So, I will stop here we will continue in the next lecture.

So, I am just trying to say that you are using a square root of  $z - \eta$  not to get to map cleverly to map  $D$  first into a sub domain of the unit disc okay. And the fact is that you are able to write this  $z - \eta$  not because there is a  $\eta$  not which is outside you are shift connected domain you are simple it that uses the fact the simply connected domain is not the whole complex plane. And the fact that you have a analytic branches of the square root is because uses. It uses the fact that the domain  $D$  is simply connected okay. So, I have stop here.
