Lecture - 7
Divided Difference Interpolation Polynomial

In the previous classes we learnt to obtain interpolating polynomials using forward differences and backward differences in the case when the information about the function is given at a set of nodal points which are equally spaced.

Then we learnt to construct an interpolation polynomial known as Lagrange interpolation polynomial for the case with the information about the function you specify that a set of points x_i which may be arbitrarily located. So now in this lecture we shall see how we can obtain an interpolating polynomial using divided differences.

(Refer Slide Time: 01:11)

So this requires definition of divided differences of various orders, so we first introduce the divided differences. So let y equal to $f(x)$ be known at say points x_i for i is equal to $0, 1, 2, 3$ upto n x_i need not be equally spaced and let $f(x_i)$ for i is equal $0, 1, 2, 3$ upto n be the corresponding values. So we define divided differences of orders $0, 1, 2, 3$ etc as follows.

So I denote by the zeroth order divided difference as $f(x_0)$ and that is nothing but the value of the function at x_0 . And then this is a divided difference of order 0. And then I introduce a divided difference of order one and denote it by $f[x_1, x_0]$ which is $f(x_1)$ minus $f(x_0)$

divided by $x_1 - x_0$. The notation is $f[x_0, x_1]$ is f at x_1 minus f at x_0 by $x_1 - x_0$. But you know that $f[x_1]$ is the zeroth order divided difference at x_1 minus zeroth order divided difference at x_0 by $x_1 - x_0$.

So the first order difference divided difference can be given in terms of the zeroth order divided differences. So this is the definition for the divided difference of order one. So we write down now the divided difference of order 2 and denote it by $f[x_0, x_1, x_2]$.

So that will be $f[x_1, x_2]$ minus $f[x_0, x_1]$ divided by $x_2 - x_0$ and we have just now constructed the divided difference of order one. So we use that definition here and divided difference of order one we again use the definition and then write down what the divided difference 2 is. So this is divided difference of order 2.

(Refer Slide Time: 05:02)

So we continue this way and I down this divided difference of order n as $f[x_0, x_1, x_2, \dots, x_n]$ minus $f[x_0, x_1, \dots, x_{n-1}]$ divided by it is going to be now $x_n - x_0$. So this is divided difference of order n. So it is possible using this definition to construct the divided difference table and from there we will be able to write down the interpolating polynomial using the information from this table.

(Refer Slide Time: 05:58)

So we are given information about x and $f(x)$ at a set of points say x_0, x_1, x_2, x_3 and the corresponding values are $f(x_0), f(x_1), f(x_2), f(x_3)$. So I would like to form the divided difference table for the given information. So I write down the column in which I'm going to get the divided differences order one.

So by definition we know this is the divided difference of order 0. This is the divided difference of order zero and so on so I require the entries in divided difference of order 1. So I know it is $f(x_1)$ minus $f(x_0)$ by x_1 minus x_0 and the notation is $f(x_0, x_1)$ and by definition it is $f(x_1)$ minus $f(x_0)$ divided by x_1 minus x_0 .

So I write this entry between these two entries and denote it as $f(x_0, x_1)$. So if I use the information here the next entry must be $f(x_1, x_2)$. And I know the definition $f(x_2)$ minus $f(x_1)$ by x_2 minus x_1 . And then the entry between these two will give me a divided difference of order one and that is $f(x_1, x_2)$.

(Refer Slide Time: 07:40)

$$f[x_0, x_1, x_2, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_n - x_0}$$

$$\rightarrow \text{divided difference of order } n$$

as follows:

order of order zero

→ divided difference of order one

→ divided difference of order two

Divided difference Table

x	$f(x)$	divided diff of order 1	divided diff of order 2
x_0	$f(x_0)$		
x_1	$f(x_1)$	$f[x_1, x_0] = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$	
x_2	$f(x_2)$	$f[x_2, x_1] = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$f[x_2, x_1, x_0] = \frac{f[x_2, x_1] - f[x_1, x_0]}{x_2 - x_0} = f[x_2, x_1, x_0]$
x_3	$f(x_3)$	$f[x_3, x_2]$	$f[x_3, x_2, x_1] = \frac{f[x_3, x_2] - f[x_2, x_1]}{x_3 - x_1}$

So having got the divided differences of order one from this table we move on to the divided differences of order to order 2. So again if you look at the definition it is $f(x_1, x_2)$ minus $f(x_0, x_1)$ by x_2 minus x_0 . So I have these two entries here so write in the middle write $f(x_1, x_2)$ minus $f(x_0, x_1)$ divided by remember it should be in out x_2 minus x_0 and this is what you denote by $f(x_0, x_1, x_2)$. So similarly you have these two entries and so you will get the second order divided difference which is $f(x_1, x_2, x_3)$ what is it it is $f(x_2, x_3)$ minus $f(x_1, x_2)$ divided by x_3 minus x_1 . So this will be $f(x_2, x_3)$ minus $f(x_1, x_2)$ divided by you have used information at points x_1, x_2, x_3 so it is divided by x_3 minus x_1 .

(Refer Slide Time: 09:08)

$$f[x_0, x_1, x_2, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_n - x_0}$$

$$\rightarrow \text{divided difference of order } n$$

Divided difference Table

x	$f(x)$	divided diff of order 1	divided diff of order 2	divided diff of order 3
x_0	$f(x_0)$			
x_1	$f(x_1)$	$f[x_1, x_0] = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$		
x_2	$f(x_2)$	$f[x_2, x_1] = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$f[x_2, x_1, x_0] = \frac{f[x_2, x_1] - f[x_1, x_0]}{x_2 - x_0} = f[x_2, x_1, x_0]$	
x_3	$f(x_3)$	$f[x_3, x_2]$	$f[x_3, x_2, x_1] = \frac{f[x_3, x_2] - f[x_2, x_1]}{x_3 - x_1}$	$f[x_3, x_2, x_1, x_0] = \frac{f[x_3, x_2, x_1] - f[x_2, x_1, x_0]}{x_3 - x_0} = f[x_3, x_2, x_1, x_0]$

So you have constructed the column in which divided differences of order 2 have been obtained. So let us now work out the column in which we have divided differences of order 3. So we have divided differences of order 2 and hence if we find $f(x_1, x_2, x_3)$ minus $f(x_0, x_1, x_2)$ and divide, so this minus this will give you; so what is it that we have to write down x_3 minus x_0 and that is going to be (x_0, x_1, x_2) and (x_1, x_2, x_3) . So this gives you the divided difference of order 3 and this is constant. So the higher order divided differences beyond the third order divided difference will all be zero for the information given in this table. And the third order divided difference is constant. So given some information about f at discrete points we use the definition of divided differences and have found the divided difference table. So with this information we should see now whether we can construct an interpolating polynomial that interpolates a function $f(x)$ at effects of discrete points x_i where the x_i need not be equally spaced.

(Refer Slide Time: 10:50)

$$f[x_0, x_1, x_2, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_n - x_0}$$
 divided difference of order n

Divided difference Table:

x	$f(x)$	divided diff of order 1	divided diff of order 2	divided diff of order 3
x_0	$f(x_0)$			
x_1	$f(x_1)$	$\frac{f(x_1) - f(x_0)}{x_1 - x_0}$		
x_2	$f(x_2)$	$\frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$\frac{f[x_2, x_1] - f[x_1, x_0]}{x_2 - x_0}$	
x_3	$f(x_3)$	$\frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$\frac{f[x_3, x_2] - f[x_2, x_1]}{x_3 - x_1}$	$\frac{f[x_3, x_2, x_1] - f[x_2, x_1, x_0]}{x_3 - x_0}$

Let $y = f(x)$ be known at $x_i, i = 0, 1, \dots, n$.
 The corresponding values of $f(x)$ are $f(x_i), i = 0, \dots, n$.
 $\sum_{i=0}^n h_i(x) \Rightarrow \frac{1}{h} f(x_i), i = 0, \dots, n$.

So let us assume that we are given information at n plus 1 points. So let Y equal to $f(x)$ be known at x_i for i is equal to $0, 1, 2, 3$ upto n . The corresponding values of $f(x)$ are $f(x_i)$ at equal to $0, 1, 2, 3$ upto n . So I want to reconstruct this function $f(x)$, so I seek a polynomial $p_n(x)$ of degree at most n that interpolates this function $f(x)$ such that, so seek $p_n(x)$ such that $p_n(x_i) = f(x_i)$ for i is equal to $0, 1, 2, 3$ upto n .

(Refer Slide Time: 11:58)

So in order to do that let us write a polynomial $p_n(x)$ in this form namely let it be A_0 plus A_1 into x minus x_0 plus A_2 into $(x$ minus $x_0)$ into $(x$ minus $x_1)$ plus A_3 into $(x$ minus x_0 minus $x_1)$ into $(x$ minus $x_2)$ plus etc. Now you know the pattern in which every term is added to this polynomial. so I see that the first term is the constant the second term is a linear polynomial the third term is a second degree polynomial the 4th term is a third degree polynomial and so the $n+1$ th term will be a n into an n th degree polynomial x minus x_0 etc upto x minus x_n .

So when it is the second term the coefficient is 1 first term coefficient is a suffix 0 third term coefficient is a suffix 2 and so on. So this is the $n+1$ th term so the coefficient is a suffix n . So we seek a polynomial in this form so let $p_n(x)$ be this. So what do we want we want p_n to satisfy condition $p_n(x_i)$ is $f(x_i)$.

(Refer Slide Time: 13:28)

The chalkboard contains the following mathematical content:

- General Polynomial Form:**

$$p_n(x) = A_0 + A_1(x-x_0) + A_2(x-x_0)(x-x_1) + A_3(x-x_0)(x-x_1)(x-x_2) + \dots + A_n(x-x_0)(x-x_1)\dots(x-x_{n-1})$$
- Zeroth Order Divided Difference:**

$$p_n(x_0) = A_0 = f(x_0) = f[x_0]$$
- First Order Divided Difference:**

$$p_n(x_1) = A_0 + A_1(x_1 - x_0) = f(x_1)$$

$$A_1 = \frac{f(x_1) - f(x_0)}{x_1 - x_0} = f[x_0, x_1]$$
- Second Order Divided Difference:**

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$
- General Form for Order n:**

$$f[x_0, x_1, \dots, x_n]$$

So let us find out what this condition is? So what is $p_n(x_0)$ it is simply A_0 because all these terms have $x - x_0$ as a Factor in them. So what is $p_n(x_0)$ must be $f(x_0)$ so A_0 is obtained but what is this is the zero th order divided difference $f(x_0)$. So we apply condition $p_n(x_1)$ is going to be A_0 plus A_1 into $x_1 - x_0$. Write A_0 but what is $p_n(x_1)$ it is $f(x_1)$.

So this tells you that $f(x_1)$ is equal to A_0 which is $f(x_0)$ plus A_1 into $x_1 - x_0$. Therefore A_1 can be written as a $f(x_1) - f(x_0)$ by $x_1 - x_0$. But that is not but zero th order difference $f(x_1) - f(x_0)$ by $x_1 - x_0$ and this is by definition the first order derivative difference $f(x_0, x_1)$. So we saw that A_0 is the zero th order difference of $f(x_0)$. A_1 is the first order difference $f(x_0, x_1)$. Let us workout the coefficient A_2 and then we can generalize and write down what A_n is in this polynomial.

(Refer Slide Time: 15:10)

$$f[x_1, x_2, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_1 - x_0}$$

divided difference of order 1

Table:

divided diff of order 2	divided diff of order 3
$\frac{f[x_1, x_2] - f[x_0, x_1]}{x_1 - x_0} = f[x_0, x_1, x_2]$	$\frac{f[x_1, x_2, x_3] - f[x_0, x_1, x_2]}{x_1 - x_0} = f[x_0, x_1, x_2, x_3]$

$$p_n(x) = A_0 + A_1(x-x_0) + A_2(x-x_0)(x-x_1) + \dots + A_n(x-x_0)(x-x_1)\dots(x-x_{n-1})$$

$$p_n(x_i) = A_0 + A_1(x_i - x_0) + A_2(x_i - x_0)(x_i - x_1) + \dots + A_n(x_i - x_0)(x_i - x_1)\dots(x_i - x_{n-1})$$

$$f(x_i) = f(x_0) + A_1(x_i - x_0) + A_2(x_i - x_0)(x_i - x_1) + \dots + A_n(x_i - x_0)(x_i - x_1)\dots(x_i - x_{n-1})$$

$$A_2 = \frac{f(x_2) - f(x_0) - A_1(x_2 - x_0)}{(x_2 - x_0)(x_2 - x_1)}$$

So let us find out what A_2 is? So I satisfy the condition $p_n(x_2)$ must be equal to $f(x_2)$. So $p_n(x_2)$ is $f(x_2)$ and that is equal to so we use that A_0 plus A_1 into x_2 minus x_0 plus A_2 into x_2 minus x_0 into x_2 minus x_1 . So we substitute for A_0 , A_0 is $f(x_0)$ plus A_1 we have already obtained A_1 and what is it? ummm and that is $f(x_0, x_1)$ multiplied by x_2 minus x_0 we do not know what A_2 is and we are trying to determine A_2 using this condition. So from here we obtain A_2 as $f(x_2)$ minus $f(x_0)$ so this minus this minus $f(x_0, x_1)$ multiplied by $(x_2 - x_0)$ divided by $(x_2 - x_0)(x_2 - x_1)$.

So A_2 is given by this expression and we expect from the pattern of the coefficients that we have got, since A_0 is the 0th order divided difference A_1 is the first order divided difference, we expect that this should give us the second order divided difference. So let us do manipulation on the terms that appear here and try to see whether what we think is going to be correct.

(Refer Slide Time: 17:20)

$$f[x_0, x_1, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_n - x_0}$$

$x_n = x_0$
 → divided difference of order n

Sequence Table:
 1st diff divided diff
 2nd diff of order 2

1st diff divided diff
 2nd diff of order 2

$$f[x_0, x_1] = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$$

$$f[x_1, x_2] = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$$

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

divided diff of order 3

$$f[x_0, x_1, x_2, x_3] = \frac{f[x_1, x_2, x_3] - f[x_0, x_1, x_2]}{x_3 - x_0}$$

$$h_n(x) = f(x_0) + A_1(x - x_0) + A_2(x - x_0)(x - x_1) + A_3(x - x_0)(x - x_1)(x - x_2) + \dots + A_n(x - x_0)(x - x_1) \dots (x - x_{n-1})$$

$$h_0(x) = f(x_0)$$

$$h_1(x) = f(x_0) + A_1(x - x_0)$$

$$h_2(x) = f(x_0) + A_1(x - x_0) + A_2(x - x_0)(x - x_1)$$

$$h_3(x) = f(x_0) + A_1(x - x_0) + A_2(x - x_0)(x - x_1) + A_3(x - x_0)(x - x_1)(x - x_2)$$

we know $x_i, i = 0, 1, \dots, n$
 values of $f(x)$ are $f(x_i), i = 0, \dots, n$
 $f(x_i), i = 0, \dots, n$

So we rewrite this term as follows, this is $f(x_2)$ minus $f(x_1)$ plus $f(x_1)$ minus $f(x_0)$. So I have subtracted $f(x_1)$ and added $f(x_1)$ then minus. What I do is I shall take this part I divide by $x_1 - x_0$ and multiply by $x_1 - x_0$. So I have not done anything except that I have added the term $f(x_1)$. The other terms remain as they are, So then I have minus $f(x_0)$ multiplied by $(x_2 - x_0)$ that is this term the whole thing is divided by $(x_2 - x_0)$ into $(x_2 - x_1)$. So let us try to see what this gives us.

(Refer Slide Time: 18:37)

$$A_2 = \frac{f(x_2) - f(x_1)}{x_2 - x_1} + f[x_0, x_1] \frac{(x_1 - x_0)(x_2 - x_0)}{(x_2 - x_0)(x_2 - x_1)}$$

$$= \frac{f(x_2) - f(x_1)}{x_2 - x_1} + \frac{f[x_0, x_1](x_2 - x_0)}{(x_2 - x_0)(x_2 - x_1)}$$

$$= \frac{f(x_2) - f(x_1)}{x_2 - x_1} + f[x_0, x_1] = f[x_0, x_1, x_2]$$

$$A_3 = f[x_0, x_1, x_2, x_3]$$

$$A_n = f[x_0, x_1, x_2, \dots, x_n]$$

$$h_n(x) = f(x_0) + f[x_0, x_1](x - x_0) + f[x_0, x_1, x_2](x - x_0)(x - x_1) + \dots + f[x_0, x_1, x_2, \dots, x_n](x - x_0)(x - x_1) \dots (x - x_{n-1})$$

Divided diff

x	$f(x)$	divided diff
x_0	$f(x_0)$	$f[x_0]$
x_1	$f(x_1)$	$f[x_0, x_1]$
x_2	$f(x_2)$	$f[x_0, x_1, x_2]$
x_3	$f(x_3)$	$f[x_0, x_1, x_2, x_3]$

Let $y = f(x)$
 The sequence of divided differences is $f[x_0, x_1, x_2, \dots, x_n]$

So A_2 will be equal to the first two terms let's write them as they are $f(x_2)$ minus $f(x_1)$. Let us look at the next term it is $f(x_1)$ minus $f(x_0)$ by x_1 minus x_0 , just see this which can be expressed in terms of zeroth order divided difference and is the first order divided difference $f[x_0, x_1]$, so this term is the first order divided difference $f[x_0, x_1]$, so we write down that term as plus $f[x_0, x_1]$ but that is multiplied by x_1 minus x_0 . So that into x_1 minus x_0 . Then I have the next term which also has the first order difference $f(x_0, x_1)$ and that is multiplied by $(x_2$ minus $x_0)$ with a negative sign.

So I shall take this term so this will be minus x_2 minus x_0 . So we have taken into account the numerator, the denominator is whole thing by x_2 minus x_0 into $(x_2$ minus $x_1)$. So we write this as $f(x_2)$ minus $f(x_1)$ by x_2 minus x_1 by x_2 minus x_0 . So I take these two terms by the denominator and put it in this way. So I am left with plus $f(x_0, x_1)$ into so I have a minus x_0 plus x_0 and I am left with $(x_1$ minus $x_2)$.

So I shall write that as minus x_2 minus x_1 . I have x_1 minus x_2 I rewrite that as minus $(x_2$ minus $x_1)$ by the denominator $(x_2$ minus $x_0)$ into $(x_2$ minus $x_1)$. So cancelling they are distinct numbers so I am left with this so can you tell me what this is? This is the 0th order divided difference at x_2 0th order divided difference at x_1 by x_2 minus x_1 and therefore this must be the first order divided difference $f(x_1, x_2)$ and what do we have here? It is the first order divided difference (x_0, x_1) and both the terms are divided by x_2 minus x_0 .

So recall the definition of the second order divided difference it is $f(x_1, x_2)$ minus $f(x_0, x_1)$ by $(x_2$ minus $x_0)$ and we denote this by $f[x_0, x_1, x_2]$ which is the second order divided difference. By looking at A_0 and A_1 we show that yes it is so. So following in the same way we can show that A_3 will be the third order difference $[x_0, x_1, x_2, x_3]$ and if I continue this way one show that A_n is the n th order divided difference x_0, x_1, x_2 etc x_n .

So which means that all the constants which appear in our polynomial $p_n(x)$ have been computed in terms of the various order divided differences. So we substitute so we obtain therefore the interpolating polynomial $p_n(x)$ of degree at most n that interpolates the function $f(x)$ at a set of discrete points x_i for i is equal to 0 to n and it is given by A_0 which is $f(x_0)$ plus A_1 which is $f(x_0, x_1)$ multiplied by x minus x_0 plus A_2 which is $f(x_0, x_1, x_2)$ multiplied by x minus x_0 into x minus x_1 plus etc. So I write down f A_n which is x_0, x_1 etc x_n into the factors will be x minus x_0 x minus x_1 etc upto x minus x_{n-1} .

(Refer Slide Time: 24:02)

$$x_n = f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]$$

$$x_n - x_0$$

divided difference of order n

see Table

divided diff of order 2	divided diff of order 3
$\frac{f[x_0, x_2] - f[x_0, x_1]}{x_2 - x_0} = f[x_0, x_1, x_2]$	$\frac{f[x_1, x_2, x_3] - f[x_0, x_1, x_2]}{x_3 - x_0} = f[x_0, x_1, x_2, x_3]$

$$p_n(x) = A_0 + A_1(x-x_0) + A_2(x-x_0)(x-x_1) + A_3(x-x_0)(x-x_1)(x-x_2) + \dots$$

$$A_2 = \frac{f(x_2) - f(x_0) - f[x_0, x_1](x_2 - x_0)}{(x_2 - x_0)(x_2 - x_1)} = f[x_0, x_1, x_2]$$

$$p_n(x_i) = f(x_i) = A_0 + A_1(x_i - x_0) + A_2(x_i - x_0)(x_i - x_1) + \dots + A_n(x_i - x_0)(x_i - x_1) \dots (x_i - x_{n-1})$$

$$A_n = \frac{f(x_n) - f(x_0) - f[x_0, x_1](x_n - x_0) - f[x_0, x_1, x_2](x_n - x_0)(x_n - x_1) - \dots - f[x_0, x_1, x_2, x_3](x_n - x_0)(x_n - x_1)(x_n - x_2)}{(x_n - x_0)(x_n - x_1) \dots (x_n - x_{n-1})}$$

So here this is $x_n - 1$ if it is A_3 we start with two its a polynomial of degree 3 when it is A_n then we have a polynomial of degree n it starts at x_0 so it goes upto $x_n - 1$. So there are n such factors so the degree of this polynomial will be n .

(Refer Slide Time: 24:26)

$$A_2 = \frac{f(x_2) - f(x_1) + f[x_0, x_1](x_2 - x_1) - (x_2 - x_0)f[x_0, x_1]}{(x_2 - x_0)(x_2 - x_1)}$$

$$= \frac{f(x_2) - f(x_1)}{x_2 - x_1} = f[x_1, x_2]$$

$$= \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0} = f[x_0, x_1, x_2]$$

$$A_3 = f[x_0, x_1, x_2, x_3]$$

$$A_n = f[x_0, x_1, x_2, \dots, x_n]$$

$$p_n(x) = f(x_0) + f[x_0, x_1](x - x_0) + f[x_0, x_1, x_2](x - x_0)(x - x_1) + \dots + f[x_0, x_1, x_2, x_3](x - x_0)(x - x_1)(x - x_2) \dots (x - x_{n-1})$$

divided difference interpolating polynomial

So we have constructed a polynomial $p_n(x)$ of degree at most n with the property that $p_n(x_i)$ will be equal to $f(x_i)$ for i is equal to $0, 1, 2, 3$ upto n . And this polynomial is called the divided difference interpolating polynomial.

(Refer Slide Time: 25:09)

$$f[x_0, x_1, x_2, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_1 - x_0}$$

\rightarrow divided difference of order n

Divided Difference Table:

x	$f(x)$	divided diff of order 1	divided diff of order 2
x_0	$f(x_0)$		
x_1	$f(x_1)$	$f[x_0, x_1] = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$	
x_2	$f(x_2)$	$f[x_1, x_2] = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$
x_3	$f(x_3)$	$f[x_2, x_3] = \frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$f[x_1, x_2, x_3] = \frac{f[x_2, x_3] - f[x_1, x_2]}{x_3 - x_1}$

Let $y = f(x)$ be known at $x_i, i = 0, 1, \dots, n$.
 The corresponding values of $f(x)$ are $f(x_i), i = 0, \dots, n$.
 $f[x_0, \dots, x_n] = \frac{f[x_1, \dots, x_n] - f[x_0, \dots, x_{n-1}]}{x_1 - x_0}$

divided diff of order 3
 $f[x_1, x_2, x_3] = \frac{f[x_2, x_3] - f[x_1, x_2]}{x_3 - x_1}$

$f(x) = A_0 + A_1(x - x_0) + A_2(x - x_0)(x - x_1) + \dots$
 $f(x_0) = A_0 = f(x_0)$
 $f(x_1) = A_0 + A_1(x_1 - x_0) = f(x_1)$
 $f(x_2) = A_0 + A_1(x_2 - x_0) + A_2(x_2 - x_0)(x_2 - x_1) = f(x_2)$
 $f(x_3) = A_0 + A_1(x_3 - x_0) + A_2(x_3 - x_0)(x_3 - x_1) + A_3(x_3 - x_0)(x_3 - x_1)(x_3 - x_2) = f(x_3)$

The greatest advantage of divided difference method is the following if suppose I have another information about this function $f(x)$ write about this function $f(x)$ say at the point x_{n+1} and the information is $f(x_{n+1})$ its just not at 1 point whatever be the number of points at which you get extra information about a function the following can be done we just explain this in case we have one additional information.

If we have one additional information then we have totally a set of $n+2$ points at which the information is available and therefore we want to reconstruct this function whose values are known at a set $n+2$ discrete points and therefore we can seek a polynomial of degree $n+1$ that interpolates this function at a set of these $n+2$ points.

(Refer Slide Time: 26:20)

$$A_2 = \frac{f(x_2) - f(x_1)}{x_2 - x_1} + f[x_1, x_2] \frac{(x - x_1)(x - x_0)}{(x_2 - x_1)(x_1 - x_0)}$$

$$= \frac{f(x_2) - f(x_1)}{x_2 - x_1} + f[x_1, x_2] \frac{(x - x_1)}{(x_2 - x_1)}$$

$$= f[x_1, x_2] = f[x_1, x_2]$$

$$A_3 = f[x_1, x_2, x_3] \dots$$

$$A_n = f[x_1, x_2, \dots, x_n]$$

$$h_n(x) = f(x_0) + f[x_0, x_1](x - x_0) + f[x_0, x_1, x_2](x - x_0)(x - x_1) + \dots + f[x_0, x_1, \dots, x_n](x - x_0)(x - x_1) \dots (x - x_{n-1})$$

Divided difference interpolation polynomial

Already we have constructed a polynomial that interpolates the same function at a set of n plus 1 points and this has been obtained using divided differences. Alright! we now have an extra information so we do not want to waste any of the efforts that we have put in, in already computing an interpolating polynomial that interpolates at n plus 1 discrete points but some little efforts that we need to give so that we get now a polynomial of degree at most n plus 1 that interpolates at a set of n plus 2 points now using this extra information at x_{n+1} $f(x_{n+1})$.

The procedure is very simple in the sense that I require the polynomial of degree n plus 1 and that is going to be the polynomial of degree n but I have already computed plus another term must be added to it so that it is A_{n+1} multiplied by $(x - x_0)(x - x_1) \dots (x - x_n)$. So you observe that there are n plus 1 such factors so this term is a polynomial of degree n plus 1.

(Refer Slide Time: 27:52)

Now I would like to see what happens to this polynomial at the point i is equal to 0 1 2 3 upto n and I observe that it is equal to $p_n(x_i)$ and because when i is equal to n this term $x - x_n$ minus $x - x_n$ will be 0 if i is 0 $x - x_0$ minus $x - x_0$ will be 0. So at all these points the contribution from this term will be 0. So you essentially have $p_{n+1}(x_i) = p_n(x_i)$ that is an interpolating polynomial interpolating the function $f(x)$ at points x_i for i is equal to 0 to n .

So p_{n+1} will satisfy the condition that at all the x_i from 0 to n $p_{n+1}(x_i) = f(x_i)$. So now let us see what will be the p_{n+1} at x_{n+1} at which the additional information is given. It is given that it must be equal to $f(x_{n+1})$ and so that must be equal to p_n evaluated at x_{n+1} which can be done plus A_{n+1} into $x_{n+1} - x_0$ etc upto $x_{n+1} - x_n$.

(Refer Slide Time: 29:20)

The chalkboard contains the following content:

Left side derivations:

$$A_2 = \frac{f(x_2) - f(x_1)}{x_2 - x_1} + \frac{f[x_2, x_1] \{ (x_1 - x_0) - (x_2 - x_0) \}}{(x_2 - x_0)(x_1 - x_0)}$$

$$= \frac{f(x_2) - f(x_1)}{x_2 - x_1} + \frac{f[x_2, x_1] (x_1 - x_0)}{(x_2 - x_0)(x_1 - x_0)}$$

$$= f[x_1, x_0] + \frac{f[x_2, x_1] (x_1 - x_0)}{(x_2 - x_0)(x_1 - x_0)}$$

$$A_3 = f[x_1, x_0] + \frac{f[x_2, x_1] (x_1 - x_0)}{(x_2 - x_0)(x_1 - x_0)} + \frac{f[x_3, x_1, x_0] (x_1 - x_0)(x_2 - x_0)}{(x_3 - x_0)(x_1 - x_0)(x_2 - x_0)}$$

$$A_n = f[x_0, x_1, \dots, x_n]$$

Right side content:

$f[x_0, x_1, x_2, \dots, x_n] = f[x_0, x_1, x_2, \dots, x_n]$

divided difference

Divided Difference Table

x	$f(x)$	divided diff of order 1	divided diff of order 2
x_0	$f(x_0)$		
x_1	$f(x_1)$	$\frac{f(x_1) - f(x_0)}{x_1 - x_0}$	
x_2	$f(x_2)$	$\frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$\frac{f[x_2, x_1] - f[x_1, x_0]}{x_2 - x_0}$
x_3	$f(x_3)$	$\frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$\frac{f[x_3, x_2] - f[x_2, x_1]}{x_3 - x_1}$

Let $y = f(x)$ be known at x_i
 The corresponding values of $f(x)$
 $f(x_i) = f(x_i), i = 0, \dots, n$
 $f(x_{n+1}) = f(x_{n+1})$

$f_n(x) = f(x)$
 $+ f[x_0, x_1] (x - x_0)$
 $+ f[x_0, x_1, x_2] (x - x_0)(x - x_1)$
 $+ \dots$
 $+ f[x_0, x_1, \dots, x_n] (x - x_0)(x - x_1) \dots (x - x_{n-1})$

$f_{n+1}(x) = f_n(x) + f[x_0, x_1, \dots, x_{n+1}] (x - x_0)(x - x_1) \dots (x - x_n)$

$f_{n+1}(x) = f(x)$
 $i = 0, 1, \dots, n$
 \rightarrow divided difference interpolation polynomial

So from here we can determine A_{n+1} , and we know from what we have already done we will end up with A_{n+1} to be the divided difference of order $n+1$ namely it'll be $f(x_0, x_1, x_2, \dots, x_{n+1})$ which we can compute. So the A_{n+1} is known we can feed it here and arrive at the interpolating polynomial of at most of degree at most $n+1$ that interpolates the function at a set of $n+2$ points.

So given the additional information about the function we do not have to waste our efforts which we have already put in to construct a polynomial of lower degree use it and add another term that incorporates this additional information given about the f and that term will give you a polynomial of the next degree finally ending up with the interpolating polynomial of the required degree that interpolates the function at a set of $n+2$ points.

(Refer Slide Time: 30:38)

$f[x_0, x_1, x_2, \dots, x_n] = f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]$

$x_n - x_0$

x_2	$f(x_2)$	$f[x_2, x_1] = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$f[x_2, x_1, x_0] = \frac{f[x_2, x_1] - f[x_1, x_0]}{x_2 - x_0}$
x_3	$f(x_3)$	$f[x_3, x_2] = \frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$f[x_3, x_2, x_1] = \frac{f[x_3, x_2] - f[x_2, x_1]}{x_3 - x_1}$

Let $y = f(x)$ be known at $x_i, i=0, 1, \dots, n$
 The corresponding values of $f(x)$ are $f(x_i), i=0, \dots, n$.

$f_0(x) \Rightarrow f_0(x) = f(x_i), i=0, \dots, n$

$x_{n+1} / f(x_{n+1})$

$f(x) = \sum_{k=0}^n L_k(x) f(x_k)$

$(x_{n+1}, f(x_{n+1})) \rightarrow$ additional information

$L_0(x) = (x-x_1)(x-x_2) \dots (x-x_n)$

$(x_1, x_2, x_3, \dots, (x-x_0))$

\Rightarrow

$\text{new } L_0(x) = \frac{(x-x_1)(x-x_2) \dots (x-x_n)(x-x_{n+1})}{(x_0-x_1) \dots (x_0-x_n)}$

divided diff of order 3

$f[x_1, x_2, x_3] - f[x_0, x_1, x_2]$

$\frac{\quad}{x_3 - x_0}$

$h(x_2) = f(x_2) = A_0 + A_1(x_2 - x_1) = f(x_1) + f[x_2, x_1](x_2 - x_1)$

$A_2 = \frac{f(x_2) - f(x_1) - f[x_2, x_1](x_2 - x_1)}{(x_2 - x_1)(x_2 - x_0)}$

What is the greatest advantage of divided difference method and the amount of calculations that are needed to construct the divided difference table is very much reduced as compared to the construction of Lagrange interpolation polynomial. So why do you say that divided difference method scores over Lagrange interpolation polynomial?

The reason is this in case you have already computed $p_n(x)$ using Lagrange interpolation polynomial say given the information at the first set of n points then what is it? it is nothing but k is equal to 0 to n $k(x)$ equal to $f(x_k)$ where $k(x)$ can be written down. Now you are given information say at x_{n+1} and the information is $f(x_{n+1})$ this is an additional information. Right? The question is can you do something like what you have done in the case of divided difference table.

No it is not possible because for example in constructing $p_n(x)$ what was your $l_0(x)$ it was $x - x_1$ into $x - x_2$ etc $x - x_n$ divided by $x_0 - x_1$ into $x_0 - x_2$ etc upto $x_0 - x_n$. But if you want to construct a polynomial of degree now $n + 1$ to incorporate this additional information the new $l_0(x)$ must be $x - x_1$ into $x - x_2$ etc upto $x - x_n$ into $x - x_{n+1}$ divided by $x_0 - x_1$ etc $x_0 - x_n$ into $x_0 - x_{n+1}$. So this must be multiplied by $f(x_0)$ to give you the first term.

(Refer Slide Time: 32:52)

The chalkboard contains the following content:

Top left: $f[x_0, x_1, x_2, \dots, x_n] = f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}] \cdot \frac{x_n - x_0}{x_1 - x_0}$

Top right: $L_n(x) = \sum_{k=0}^n L_k(x) f(x_k)$

Right side: $L_n(x) = A_0 + A_1(x-x_0) + A_2(x-x_0)(x-x_1) + A_3(x-x_0)(x-x_1)(x-x_2) + \dots$

Center: $L_n(x) = \sum_{k=0}^n \frac{f(x_k) \prod_{j \neq k} (x - x_j)}{(x_k - x_j) \prod_{j \neq k} (x_k - x_j)}$

Bottom left: $L_n(x) = f(x_0) + \frac{f(x_1) - f(x_0)}{x_1 - x_0} (x - x_0) + \frac{f(x_2) - f(x_1) - \frac{f(x_2) - f(x_0)}{x_2 - x_0} (x - x_0)}{(x_2 - x_1) - \frac{x_2 - x_0}{x_1 - x_0} (x_1 - x_0)} (x - x_0)(x - x_1) + \dots$

Bottom right: $L_n(x) = f(x_0) + \frac{f(x_1) - f(x_0)}{x_1 - x_0} (x - x_0) + \frac{f(x_2) - f(x_1) - \frac{f(x_2) - f(x_0)}{x_2 - x_0} (x - x_0)}{(x_2 - x_1) - \frac{x_2 - x_0}{x_1 - x_0} (x_1 - x_0)} (x - x_0)(x - x_1) + \dots$

Table: Divided Difference Table

x	$f(x)$	divided diff of order 1	divided diff of order 2
x_0	$f(x_0)$		
x_1	$f(x_1)$	$\frac{f(x_1) - f(x_0)}{x_1 - x_0}$	
x_2	$f(x_2)$	$\frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$\frac{\frac{f(x_2) - f(x_1)}{x_2 - x_1} - \frac{f(x_1) - f(x_0)}{x_1 - x_0}}{x_2 - x_0}$
x_3	$f(x_3)$	$\frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$\frac{\frac{f(x_3) - f(x_2)}{x_3 - x_2} - \frac{f(x_2) - f(x_1)}{x_2 - x_1}}{x_3 - x_1}$

Let $y = f(x)$ be known at $x_i, i = 0, 1, \dots, n$. The corresponding values of $f(x)$ are $f(x_i), i = 0, \dots, n$.

Let $L_n(x) = \sum_{k=0}^n L_k(x) f(x_k)$

Similarly each of those polynomial $L_k(X)$ and $p_{n+1}(x)$ now will be $\sum_{k=0}^n L_k(x) f(x_k)$ so each of these polynomials $L_k(x)$ where k equal to 0 to n plus 1 will have in both the numerator and the denominator extra factor that comes because of the information at $x_{n+1}, f(x_{n+1})$. And therefore the previous calculations are their parts that we have put in to construct a polynomial of degree n that is the function at a set of $N + 1$ points will not be of any help to us in getting a polynomial of degree $n + 1$.

And therefore the calculations have to be performed once again to construct this polynomial of degree n plus one where an additional information is given about the function. Whereas this did not happen in the case of the divided difference formula the information the polynomial that we already have obtained is going to be used and we just add an extra term that takes into account the information that is provided to us at this extra point. And that is why the divided difference method scores over Lagrange interpolation method.

So now that we know the definition of what the divided differences are? How to construct divided difference table and what is the interpolating polynomial that is based on divided differences. Let us take a simple example and then construct an interpolating polynomial based on divided differences.

(Refer Slide Time: 34:44)

Find the interpolating polynomial using divided differences.

divided difference of order n

$$\frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_n - x_0}$$

divided difference Table

$f(x_i)$	divided diff of order 1	divided diff of order 2
$f(x_0)$		
$f(x_1)$	$\frac{f(x_1) - f(x_0)}{x_1 - x_0}$	
$f(x_2)$	$\frac{f(x_2) - f(x_1)}{x_2 - x_1}$	$\frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$
$f(x_3)$	$\frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$\frac{f[x_2, x_3] - f[x_1, x_2]}{x_3 - x_1}$

$y = f(x)$ has known at $x_i, i = 0, 1, \dots, n$
 corresponding values of $f(x)$ are $f(x_i), i = 0, \dots, n$
 $\Rightarrow \frac{1}{h} (f_i) = f(x_i), i = 0, \dots, n$
 $x_{n+1} / f(x_{n+1})$ $(n+1) / (k)$

x	f
0	1
1	2
2	3
4	5

Ok Let us find the interpolating polynomial using divided differences. So the information is given at x and the corresponding f values 0 1 2 and 4, and the corresponding values are 1 2 and 5 I am just illustrating the procedure so taking some simple example where information at Four distinct Points are given. So the first thing that we should look at is; are the x values equally spaced? No they are not equally spaced.

So in order to get an interpolating polynomial I can use either Lagrange interpolation polynomial or divided difference interpolation polynomial. So now that we have learned divided differences let us use the divided differences and that is what the question is so we shall obtain the divided difference stable and then construct that polynomial.

(Refer Slide Time: 36:10)

$x_0, \dots, x_n = [f(x_0, x_2, \dots, x_n) - f(x_0, x_1, \dots, x_{n-1})]$

$x_n - x_0$

→ divided difference of order 1

difference table:

divided diff of order 1	divided diff of order 2
$f[x_0, x_1] = \frac{f(x_1) - f(x_0)}{x_1 - x_0}$ $f[x_1, x_2] = \frac{f(x_2) - f(x_1)}{x_2 - x_1}$ $f[x_2, x_3] = \frac{f(x_3) - f(x_2)}{x_3 - x_2}$	$f[x_0, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$ $f[x_1, x_3] = \frac{f[x_2, x_3] - f[x_1, x_2]}{x_3 - x_1}$

Find the interpolating polynomial using divided differences.

x	f	1 st order divided diff	2 nd order divided diff	3 rd order divided diff
0.2	1.5			
1.2	1.5	$\frac{1-1}{1-0} = 0 = f[x_0, x_1]$		
2	2	$\frac{2-1}{2-1} = 1 = f[x_1, x_2]$	$\frac{1-0}{2-0} = \frac{1}{2} = f[x_0, x_2]$	
4	5	$\frac{5-2}{4-2} = \frac{3}{2} = f[x_2, x_3]$	$\frac{3-1}{4-1} = \frac{2}{3} = f[x_1, x_3]$	$\frac{\frac{1}{2} - \frac{1}{2}}{4-0} = -\frac{1}{12} = f[x_0, x_3]$

(x) we know at $x_i, i=0, \dots, n$

boundary values of $f(x)$ are $f(x_i), i=0, \dots, n$.

$f(x_i) = f(x_i), i=0, \dots, n$.

$x_{n+1} / f(x_{n+1})$

$(n+1) / PK$

So I form the divided differences of order 0, so what is it? this is our x_0 this is x_1 so this is our zeroth order divided difference x_0 this is first zeroth order divided difference $f(x_1)$. So the divided differences of order 1 can be constructed by this minus this so 1 minus 1 divided by x_1 minus x_0 so 0 then 2 minus 1 by 2 minus 1 then 5 minus 2 by 4 minus 2 , so these are the divided differences of order 1 and we know that this by notation is $f(x_0, x_1)$.

So now I compute second order divided differences. So this is by notation $f[x_1, x_2]$. So how do you compute the second order difference. The difference between the successive first order difference is 1 minus 0 divided by x_2 minus x_0 this is x_2 and that is x_0 . So 2 minus 0 so it is half. And then 3 by 2 minus 1 divided by x_2 minus x_1 , so 4 minus 1 , so it is going to be half by 3 so 1 by 6 . How do you denote? This is $f[x_0, x_1, x_2]$ and this is $f[x_1, x_2, x_3]$, these are the second order differences so we form the third order divided difference.

So that is going to be by definition 1 by 6 minus half divided by x^3 minus x^0 so it is 4 minus 0 and the value is going to be minus 1 by 12 . So the third order given information at four distinct points the third order difference divided difference is constant and the divided differences of order beyond 3 will all be 0 . And how do you denote this, this is $f(x_0, x_1, x_2, x_3)$

(Refer Slide Time: 38:58)

$x_2, x_3, \dots, x_n] = \frac{f[x_1, x_2, \dots, x_n] - f[x_0, x_1, \dots, x_{n-1}]}{x_n - x_0}$

\hookrightarrow divided difference of order 1

difference Table:

divided diff of order 1	divided diff of order 2
$\frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0} = f[x_0, x_1, x_2]$	$\frac{f[x_1, x_2, x_3] - f[x_0, x_1, x_2]}{x_3 - x_0} = f[x_0, x_1, x_2, x_3]$
$\frac{f[x_2, x_3] - f[x_1, x_2]}{x_3 - x_1} = f[x_1, x_2, x_3]$	$\frac{f[x_2, x_3, x_4] - f[x_1, x_2, x_3]}{x_4 - x_1} = f[x_1, x_2, x_3, x_4]$

$f(x)$ we know of $x_i, i=0, \dots, n$
 corresponding values of $f(x)$ are $f(x_i), i=0, \dots, n$.

$f(x_i) = f(x_i), i=0, \dots, n$.

$x_{n+1} / f(x_{n+1})$

Find the interpolating polynomial using divided differences.

x	f	1 st order divided diff	2 nd order divided diff	3 rd order divided diff
0.2	1.5			
1.2	1.0	$\frac{1-1.5}{1-0.2} = -0.625$		
2	2.1	$\frac{2-1}{2-1.2} = 1.667$	$\frac{1-0}{2-0.2} = \frac{1}{1.8} = \frac{1}{2}$	
4	5	$\frac{5-2}{4-2} = \frac{3}{2}$	$\frac{3-1}{4-1.2} = \frac{2}{2.8} = \frac{1}{1.4}$	$\frac{1}{4} - \frac{1}{2} = -\frac{1}{4}$
			$\frac{1}{4-0} = \frac{1}{4}$	$\frac{1}{4} - \frac{1}{2} = -\frac{1}{4}$
				$\frac{1}{4} - \frac{1}{2} = -\frac{1}{4}$

$f(x) = 1 + 0(x-0.2) + \frac{1}{2}(x-0.2)(x-1.2) - \frac{1}{12}(x-0.2)(x-1.2)(x-2)$

$= 1 + \frac{1}{2}(x-0.2)(x-1.2) - \frac{1}{12}(x-0.2)(x-1.2)(x-2)$

$= 1 + \frac{x^3}{12} + \frac{3x^2}{4} - \frac{2x}{3} + 1$

So we use this information in seeking a polynomial of degree 3, so the required polynomial $p_3(x)$ that approximates the function $f(x)$ is given by first term $f(x_0)$ which is 1 plus $f'(x_0)(x - x_0)$ plus $\frac{f''(x_0)}{2!}(x - x_0)^2$ plus $\frac{f'''(x_0)}{3!}(x - x_0)^3$ minus 1 by 12 into $(x - x_0)^4$ into $(x - x_0)^5$ into $(x - x_0)^6$ into $(x - x_0)^7$ into $(x - x_0)^8$ into $(x - x_0)^9$ into $(x - x_0)^{10}$ into $(x - x_0)^{11}$ into $(x - x_0)^{12}$. So the polynomial is $1 + \frac{1}{2}(x - 0)^2 + \frac{1}{6}(x - 0)^3 - \frac{1}{12}(x - 0)^4 + \dots$ (1 is 1 and x^2 is 2).

So you see that you have a third degree polynomial that approximates this function or reconstructs these function errands in this interval between 0 and 4. So if you simplify this it turns out to be minus X cubed by 12 plus 3 x square by 4 minus 2 by $3x$ plus 1. So this is required interpolating polynomial of degree 3 that interpolates the function at a set of four distinct points. So we now have understood how we can construct interpolating polynomial using divided difference.
