Variational problems with a movable boundary for a functional dependent on two functions

Hello friends welcome to my lecture on variational problems with a movable boundary for a functional dependent on two functions.

(Refer Slide Time: 0:32)

Variational problem with a movable boundary for a functional dependent on two functions:

Consider the functional

$$I[y(x), z(x)] = \int_{x_1}^{x_2} F(x, y(x), z(x), y'(x), z'(x)) dx. \quad \dots(1)$$

Let the point $A(x_1, y_1, z_1)$ be fixed and the other point $B(x_2, y_2, z_2)$ move in an arbitrary manner, or along a curve on a surface.

From Euler's equation, extremal can be attained only on the integral curves of

$$\frac{\partial F}{\partial y} - \frac{d}{dx} \left(\frac{\partial F}{\partial y'} \right) = 0, \quad \frac{\partial F}{\partial z} - \frac{d}{dx} \left(\frac{\partial F}{\partial z'} \right) = 0.$$

 IIT ROORKEE  NPTEL ONLINE CERTIFICATION COURSE

2

Let us consider the functional $I[y, z]$ where y and z are two dependent variables and x is an independent variable, the functional is $\int_{x_1}^{x_2} F(x, y, z, y', z') dx$. Let us consider a point $A(x_1, y_1, z_1)$ which is fixed and the other point $B(x_2, y_2, z_2)$ move in an arbitrary manner, or it moves along a curve or it moves on a surface.

From Euler's Equations, the extremal can be attained only on the integral curves of the two equations $\frac{\partial F}{\partial y} - \frac{d}{dx} \left(\frac{\partial F}{\partial y'} \right) = 0$, $\frac{\partial F}{\partial z} - \frac{d}{dx} \left(\frac{\partial F}{\partial z'} \right) = 0$ because we know that the necessary conditions for the extremal in the case of more than one dependent variable are the two equations given by the Euler's Equations here. So the extremal can be attained only on those curves.

(Refer Slide Time: 1:32)

The general solution of these equations contains four arbitrary constants. Since $A(x_1, y_1, z_1)$ is fixed, it is possible to eliminate two arbitrary constants. The other two constants have to be determined from the necessary condition $\delta I = 0$ for extremum, where δI is the variation of I

$$\delta I = \left(F - y' \frac{\partial F}{\partial y'} - z' \frac{\partial F}{\partial z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} \right)_{x=x_2} \delta y_2 + \left(F_{z'} \right)_{x=x_2} \delta z_2 = 0 \quad \dots(2)$$

for an extremum.

Now the general solution of these equations contains four arbitrary constants. Since x_1, y_1, z_1 is fixed it is possible to eliminate two arbitrary constants. The other two arbitrary constants have to determine from the necessary condition that is δI equal to 0 where δI is the variation of I . Now δI is equal to F minus y' dash δF over $\delta y'$ dash minus z' dash δF over $\delta z'$ dash x equal to x_2 into δx_2 plus $F_{y'}$ dash x equal to x_2 into δy_2 plus $F_{z'}$ dash x equal to x_2 δz_2 equal to 0 for an extremum.

(Refer Slide Time: 2:12)

If $\delta x_2, \delta y_2, \delta z_2$ are independent then

$$\left(F - y' F_{y'} - z' F_{z'} \right)_{x=x_2} = 0, \quad \left(F_{y'} \right)_{x=x_2} = 0, \quad \left(F_{z'} \right)_{x=x_2} = 0.$$

If the boundary point (x_2, y_2, z_2) moves along some curve

$$y_2 = \phi(x_2), \quad z_2 = \psi(x_2).$$

Then

$$\delta y_2 = \phi'(x_2) \delta x_2, \quad \delta z_2 = \psi'(x_2) \delta x_2,$$

The general solution of these equations contains four arbitrary constants. Since $A(x_1, y_1, z_1)$ is fixed, it is possible to eliminate two arbitrary constants. The other two constants have to be determined from the necessary condition $\delta I = 0$ for extremum, where δI is the variation of I

$$\delta I = \left(F - y' \frac{\partial F}{\partial y'} - z' \frac{\partial F}{\partial z'} \right)_{x=x_2} \delta x_2 + (F_{y'})_{x=x_2} \delta y_2 + (F_{z'})_{x=x_2} \delta z_2 = 0 \quad \dots(2)$$

for an extremum.

Now if δx_2 , δy_2 , δz_2 are all independent here then their coefficients must be 0 and so $F - y' \frac{\partial F}{\partial y'} - z' \frac{\partial F}{\partial z'} \bigg|_{x=x_2} = 0$, $F_{y'} \big|_{x=x_2} = 0$ and $F_{z'} \big|_{x=x_2} = 0$. Now if the boundary point x_2, y_2, z_2 moves along some curve and the equations of the curves are $y_2 = \phi(x_2)$, $z_2 = \psi(x_2)$ then from $y_2 = \phi(x_2)$ we have $\delta y_2 = \phi'(x_2) \delta x_2$ and $z_2 = \psi(x_2)$ gives $\delta z_2 = \psi'(x_2) \delta x_2$.

(Refer Slide Time: 2:51)

Thus from (2), we have

$$\left(F + (\phi' - y')F_{y'} + (\psi' - z')F_{z'} \right)_{x=x_2} \delta x_2 = 0.$$

Since δx_2 is arbitrary, we have

$$\left(F + (\phi' - y')F_{y'} + (\psi' - z')F_{z'} \right)_{x=x_2} = 0.$$

This is the transversality condition for the extremum of (1). Along with the equations $y_2 = \phi(x_2)$ and $z_2 = \psi(x_2)$, this condition gives the equations necessary for determining the two arbitrary constants in the general solution of Euler's equations.

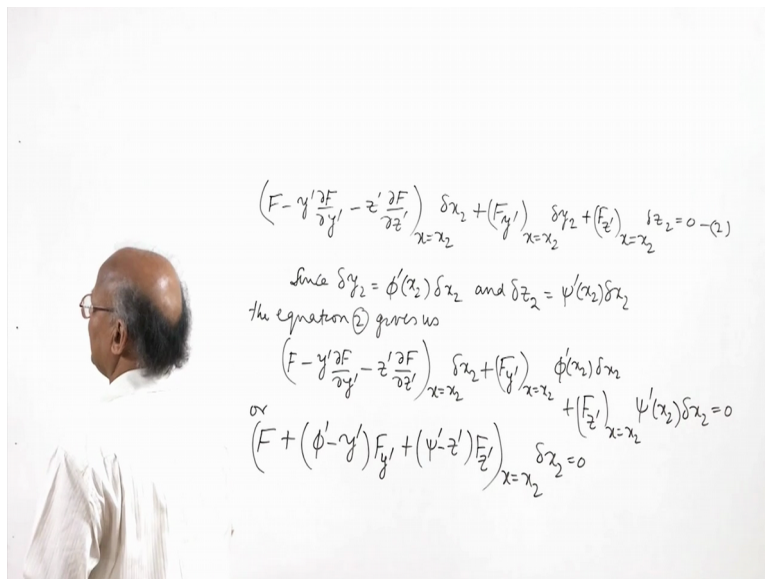

The general solution of these equations contains four arbitrary constants. Since $A(x_1, y_1, z_1)$ is fixed, it is possible to eliminate two arbitrary constants. The other two constants have to be determined from the necessary condition $\delta I = 0$ for extremum, where δI is the variation of I

$$\delta I = \left(F - y' \frac{\partial F}{\partial y'} - z' \frac{\partial F}{\partial z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} \right)_{x=x_2} \delta y_2 + \left(F_{z'} \right)_{x=x_2} \delta z_2 = 0 \quad \dots(2)$$

for an extremum.

So from the equation 2 from the equation 2 means this equation.

(Refer Slide Time: 3:00)

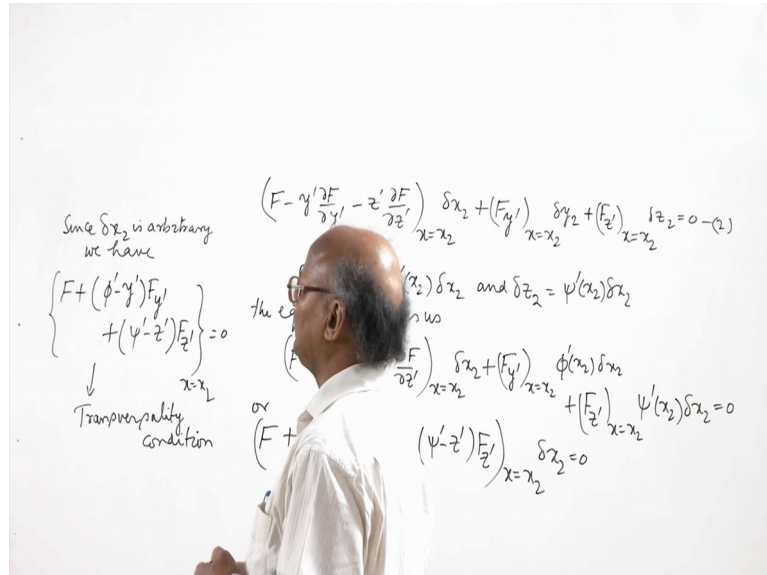

What we will have is F minus δF by δy dash minus z dash, δF by δz dash into δx_2 plus $F_{y'}$ dash δy_2 plus $F_{z'}$ dash δz_2 equal to 0. Now we have δy equal δy_2 since δy_2 equal to $\phi'(x_2) \delta x_2$ and δz_2 equal to $\psi'(x_2) \delta x_2$ this equation okay this equation we have called as 2 the equation 2 gives us F minus y dash $F_{y'}$ dash δy_2 is $\phi'(x_2) \delta x_2$ and then $F_{z'}$ dash δz_2 is $\psi'(x_2) \delta x_2$ equal to 0.

So let us we can write it as then or F plus ϕ' dash minus y dash $F_{y'}$ dash plus ψ' dash minus z dash into $F_{z'}$ dash at x equal to x_2 δx_2 equal to 0 because we can collect the coefficients here δx_2 , δx_2 , δx_2 so this is F plus ϕ' dash at x equal to x_2 is ϕ'

dash x_2 and then ϕ' dash x_2 F_y dash at x equal to x_2 into δx_2 so this is here and then minus y dash F_y dash δx_2 it is here and then F_z dash ψ' dash x_2 into δx_2 is here and minus z dash F_z dash into δx_2 is here, so we can write like this.

(Refer Slide Time: 6:44)

And since δx_2 is arbitrary we have F plus ϕ' dash minus y dash F_y dash plus ψ' dash minus z dash F_z dash at x equal to x_2 is equal to 0, this is the transversality condition this is transversality condition. When the point x_2, y_2, z_2 moves on a curve then this is the transversality condition for the extremum of the functional one.

(Refer Slide Time: 7:54)

Thus from (2), we have

$$\left(F + (\phi' - y')F_{y'} + (\psi' - z')F_{z'} \right)_{x=x_2} \delta x_2 = 0.$$

Since δx_2 is arbitrary, we have

$$\left(F + (\phi' - y')F_{y'} + (\psi' - z')F_{z'} \right)_{x=x_2} = 0.$$

This is the transversality condition for the extremum of (1). Along with the equations $y_2 = \phi(x_2)$ and $z_2 = \psi(x_2)$, this condition gives the equations necessary for determining the two arbitrary constants in the general solution of Euler's equations.

IIT ROORKEE
 NPTEL ONLINE CERTIFICATION COURSE

5

Now along with the equation y_2 equal to $\phi(x_2)$ and z_2 equal $\Psi(x_2)$ this transversality condition gives the equations necessary for determining the remaining two arbitrary constants in the general solution of Eulers Equations.

(Refer Slide Time: 8:02)

In the case, the boundary point (x_2, y_2, z_2) moves along a given surface $z_2 = \phi(x_2, y_2)$ then

$$\delta z_2 = \phi_{x_2} \delta x_2 + \phi_{y_2} \delta y_2$$

such that the variations δx_2 and δy_2 are arbitrary.

In this case, equation (2) \Rightarrow

$$\left(F - y'F_{y'} + (\phi_x - z')F_{z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} + \phi_{y'} F_{z'} \right)_{x=x_2} \delta y_2 = 0.$$

Since δx_2 and δy_2 are independent, we get

$$\left(F - y'F_{y'} + (\phi_x - z')F_{z'} \right)_{x=x_2} = 0$$

III ROORKEE NPTEL ONLINE CERTIFICATION COURSE 6

Now in case the boundary point x_2, y_2, z_2 moves along a given surface we know that the equation of a surface can be written as z equal to $\phi(x, y)$. So in that case z_2 will be equal to $\phi(x_2, y_2)$. Now z_2 equal to $\phi(x_2, y_2)$ and z equal to $\phi(x, y)$ gives us the increment in z_2 that is because x_2, y_2, z_2 is the moving points so δz_2 will be partial derivative of ϕ with respect to x at x equal to x_2 into δx_2 then partial derivative of y at y_2 so ϕ_{y_2} into δy_2 . The variations δx_2 and δy_2 are arbitrary.

(Refer Slide Time: 8:54)

$$\left(F - y'F_{y'} - z'F_{z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} \right)_{x=x_2} \delta y_2 + \left(F_{z'} \right)_{x=x_2} \delta z_2 = 0$$

Since $\delta z_2 = \phi_{x_2} \delta x_2 + \phi_{y_2} \delta y_2$

we get

$$\left(F - y'F_{y'} - z'F_{z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} \right)_{x=x_2} \delta y_2 + \left(F_{z'} \right)_{x=x_2} \left\{ \phi_{x_2} \delta x_2 + \phi_{y_2} \delta y_2 \right\} = 0$$

or

$$\left(F - y'F_{y'} + (\phi_x - z')F_{z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} + \phi_{y_2} F_{z'} \right)_{x=x_2} \delta y_2 = 0$$

$$\begin{aligned}
 & (F - y'F_y - z'F_z)_{x=x_2} \delta x_2 + (F_y)_{x=x_2} \delta y_2 + (F_z)_{x=x_2} \delta z_2 = 0 \\
 & \text{we get} \quad \text{Since } \delta z_2 = (\phi_x)_{x=x_2} \delta x_2 + (\phi_y)_{x=x_2} \delta y_2 \\
 & (F - y'F_y - z'F_z)_{x=x_2} \delta x_2 + (F_y)_{x=x_2} \delta y_2 + (F_z)_{x=x_2} \{ (\phi_x)_{x=x_2} \delta x_2 + (\phi_y)_{x=x_2} \delta y_2 \} = 0 \\
 & \text{or} \\
 & \left\{ F - y'F_y + (\phi_x - z')F_z \right\}_{x=x_2} \delta x_2 + \left\{ F_y + \phi_y F_z \right\}_{x=x_2} \delta y_2 = 0
 \end{aligned}$$

Now in this case the equation 2 will take the following form equation 2 which is $F - y'F_y - z'F_z$ at $x = x_2$ plus F_y at $x = x_2$ delta x_2 plus F_z at $x = x_2$ delta z_2 equal to 0. This equation in this case will take the form δz_2 is so since δz_2 is equal to $\phi_x x_2 + \phi_y y_2$, $\phi_x x_2$ means ϕ_x at $x = x_2$, okay δx_2 plus ϕ_y at $y = y_2$ or $x = x_2$, then δy_2 .

So let us use this here then we can write it as $F - y'F_y$ is equal to this we get $F - y'F_y$ and then here F_y at $x = x_2$, okay minus $z'F_z$ at $x = x_2$ delta x_2 plus F_y at $x = x_2$ delta y_2 plus we have put F_z at $x = x_2$ delta z_2 is ϕ_x at $x = x_2$ delta x_2 plus ϕ_y at $y = y_2$ delta y_2 equal to 0. So we can write it as or $F - y'F_y - F_y$ at $x = x_2$ delta x_2 it can be combined with this term here.

So we can write ϕ_x minus $z'F_z$ into δx_2 at $x = x_2$ plus and this term can be combined with the term here so we write $F - y'F_y + \phi_y F_z$ at $x = x_2$ delta y_2 equal to 0. So we get $F - y'F_y - F_y$ at $x = x_2$ delta x_2 plus F_y at $x = x_2$ delta y_2 plus ϕ_x minus $z'F_z$ at $x = x_2$ delta x_2 plus F_y at $x = x_2$ delta y_2 equal to 0.

(Refer Slide Time: 12:38)

In the case, the boundary point (x_2, y_2, z_2) moves along a given surface $z_2 = \phi(x_2, y_2)$ then

$$\delta z_2 = \phi_{x_2} \delta x_2 + \phi_{y_2} \delta y_2$$

such that the variations δx_2 and δy_2 are arbitrary.

In this case, equation (2) \Rightarrow

$$\left(F - y' F_{y'} + (\phi_x - z') F_{z'} \right)_{x=x_2} \delta x_2 + \left(F_{y'} + \phi_{y_2} F_{z'} \right)_{x=x_2} \delta y_2 = 0.$$

Since δx_2 and δy_2 are independent, we get

$$\left(F - y' F_{y'} + (\phi_x - z') F_{z'} \right)_{x=x_2} = 0$$

Now since δx_2 and δy_2 are independent we get $F - y' F_{y'} + \phi_x - z' F_{z'}$ at $x = x_2$ is 0 and also $F_{y'} + \phi_{y_2} F_{z'}$ equal to 0.

(Refer Slide Time: 12:50)

and

$$\left(F_{y'} + \phi_{y_2} F_{z'} \right)_{x=x_2} = 0.$$

These two conditions together with $z_2 = \phi(x_2, y_2)$ enable us to determine two arbitrary constants in the general solution of Euler's equation.

So these two equations along with the fact that x_2, y_2, z_2 lies on $z = \phi(x, y)$ we get $z_2 = \phi(x_2, y_2)$ so these equations enable us to get the remaining two arbitrary constants in the general solution of the Euler's Equation.

(Refer Slide Time: 13:08)

Example 1: Find the shortest distance of the point $(0, 2, 4)$ to the straight line

$$\frac{x-1}{1} = \frac{y}{3} = \frac{z}{4}.$$

Solution : We have

$$I(y(x), z(x)) = \int_0^{x_2} \sqrt{1 + y'^2 + z'^2} dx,$$

here $F(x, y, z, y', z') = \sqrt{1 + y'^2 + z'^2}$

and $\frac{x-1}{1} = \frac{y}{3} = \frac{z}{4} \Rightarrow y = 3x - 3 = \phi(x), z = 4x - 4 = \psi(x), \text{ (say).}$

Now let us take the example on this article let us find the shortest distance of the point 0 to 4 to the straight line given by $\frac{x-1}{1}, \frac{y}{3}, \frac{z}{4}$ these equations of the line are given in the symmetric form. So we know that $I(y(x), z(x))$ is integral because the x_1 point is 0, this is x_1, y_1, z_1 which is a fixed point so x_1 is 0 here, x_2, y_2, z_2 is a variable point which will lie on the line given here so and then we want to find the shortest distance we know the formula $dx^2 + dy^2 + dz^2$ under root that is ds .

So when we write it as we write ds over dx into dx , ds over dx can be written as square root 1 plus $\frac{dy}{dx}$ whole square plus $\frac{dz}{dx}$ whole square, so we have written it as under root 1 plus y' square plus z' square into dx and the limits of integration are x_1 equal to 0 and x_2 is a variable, so $x_1 = 0$ goes 0 to x_2 . So here $F(x, y, z, y', z')$ is equal to square root 1 plus y' square plus z' square.

Now the equations of the lines $\frac{x-1}{1} = \frac{y}{3}$ gives us y equal to $3x - 3$, so we can write it as a function of x say $\phi(x)$ and $\frac{x-1}{1} = \frac{z}{4}$ gives us the other equation z equal to $4x - 4$, we can denote it by $\psi(x)$. So y is a function of x and z is a function of x .

(Refer Slide Time: 14:55)

From Euler's equations, we have

$$\frac{\partial F}{\partial y} - \frac{d}{dx} F_{y'} = 0, \quad \frac{\partial F}{\partial z} - \frac{d}{dx} F_{z'} = 0$$

$$\Rightarrow \frac{y'}{(1+y'^2+z'^2)^{1/2}} = c_1, \quad \dots(1)$$

$$\frac{z'}{(1+y'^2+z'^2)^{1/2}} = c_2 \quad \dots(2)$$

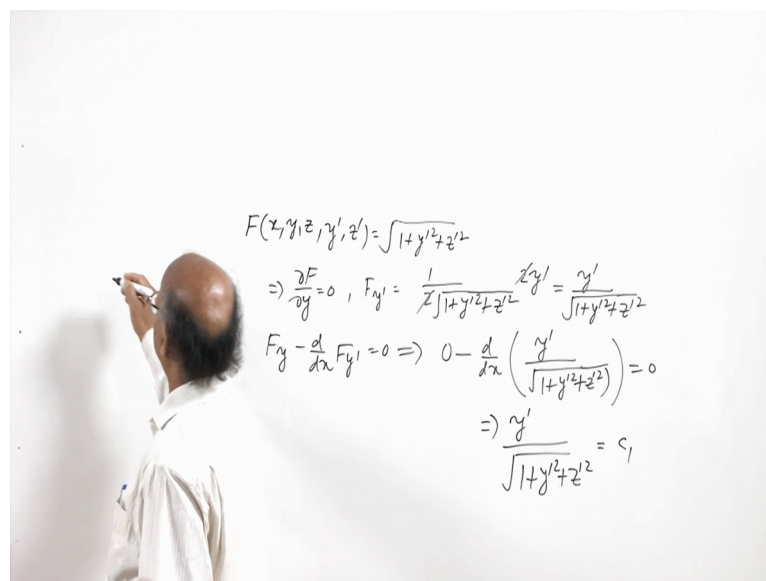

and so $y' = c_3 z'$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE

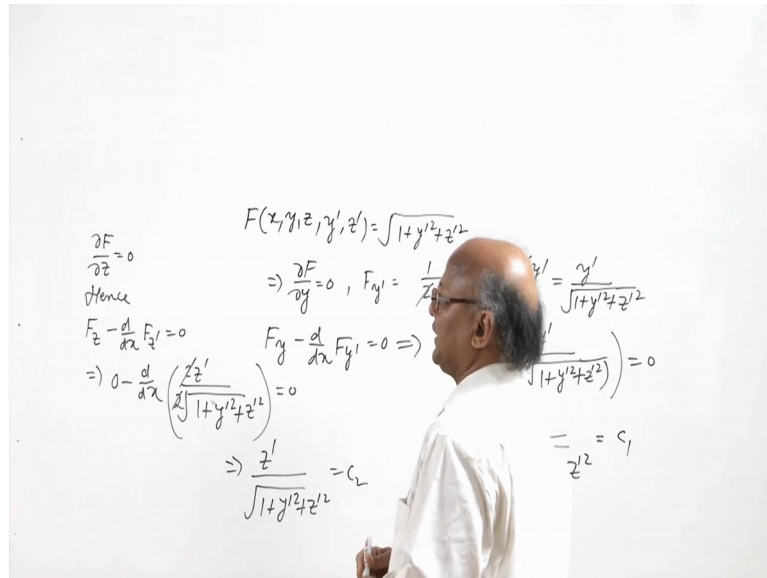

9

Now the Euler's Equation are for the extremal the Euler's Equation are $F_y - \frac{d}{dx} F_{y'} = 0$, $F_z - \frac{d}{dx} F_{z'} = 0$.

(Refer Slide Time: 15:10)

$F(x, y, z, y', z') = \sqrt{1+y'^2+z'^2}$
 $\Rightarrow \frac{\partial F}{\partial y} = 0, \quad F_{y'} = \frac{1}{\sqrt{1+y'^2+z'^2}} \cdot z' y' = \frac{y' z'}{\sqrt{1+y'^2+z'^2}}$
 $F_y - \frac{d}{dx} F_{y'} = 0 \Rightarrow 0 - \frac{d}{dx} \left(\frac{y' z'}{\sqrt{1+y'^2+z'^2}} \right) = 0$
 $\Rightarrow \frac{y' z'}{\sqrt{1+y'^2+z'^2}} = c_1$

So since our extremal is since our $F(x, y, z, y', z')$ is equal to square root 1 plus y' dash square plus z' dash square F is independent of y . So its partial derivative with respect to y is 0 and therefore $F_y - \frac{d}{dx} F_{y'} = 0$ gives us 0 minus $\frac{d}{dx}$ of $F_{y'}$. Now here $F_{y'}$ if you find then $F_{y'}$ is $\frac{1}{2\sqrt{1 + y'^2 + z'^2}}$ so this is y' dash divided by under root 1 plus y' dash square plus z' dash square. Let us put it here, so y' dash divided by under root 1 plus y' dash square plus z' dash square, so this is equal to 0.

So first equation gives us y' dash divided by since derivative of y' dash divided by under root 1 plus y' dash square, z' dash square to the power half is 0, this gives y' dash divided by under root 1 plus y' dash square plus z' dash square is equal to some constant let us take this constant as c_1 and similarly let us note that the $F(x, y, z, y', z')$ independent is independent of z .

So partial derivative of F with respect to z is also 0, hence $F_z - \frac{d}{dx} F_{z'} = 0$ gives us 0 minus $\frac{d}{dx}$ of derivative of F with respect to z' is $\frac{z'}{\sqrt{1 + y'^2 + z'^2}}$ so this 2 cancels out with this and we get z' dash divided by square root 1 plus y' dash square plus z' dash square is equal to 0, $\frac{d}{dx}$ of this $\frac{d}{dx}$ of this is 0 so this is some constant let us say c_2 .

(Refer Slide Time: 17:58)

From Euler's equations, we have

$$\frac{\partial F}{\partial y} - \frac{d}{dx} F_{y'} = 0, \quad \frac{\partial F}{\partial z} - \frac{d}{dx} F_{z'} = 0$$

$$\Rightarrow \frac{y'}{(1 + y'^2 + z'^2)^{1/2}} = c_1, \quad \dots(1)$$

$$\frac{z'}{(1 + y'^2 + z'^2)^{1/2}} = c_2 \quad \dots(2)$$

and so $y' = c_3 z'$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 9

$$(2) \Rightarrow \frac{z'}{(1 + (1 + c_3^2)z'^2)^{1/2}} = c_2.$$

Hence $z' = \frac{c_2}{(1 - c_2^2 - c_2^2 c_3^2)^{1/2}} = c_4,$

$$\Rightarrow z = c_4 x + c_5. \quad \dots(3)$$

Now $y' = c_3 z' \Rightarrow y = c_6 x + c_7. \quad \dots(4)$

 IIT ROORKEE
  NPTEL ONLINE CERTIFICATION COURSE
 10

So we get these two equations $y' / \sqrt{1 + y'^2 + z'^2} = c_1$, $z' / \sqrt{1 + y'^2 + z'^2} = c_2$. So let us divide these two equations then we get $y' / z' = c_1 / c_2$ and c_1 / c_2 is another arbitrary constant we can write it as c_3 . So y' is equal to $c_3 z'$.

Now let us put the value of y' equal to $c_3 z'$ in this equation $z' / \sqrt{1 + y'^2 + z'^2} = c_2$ we will get $z' / \sqrt{1 + 1 + c_3^2 z'^2} = c_2$ or we can solve it for z' $z' = c_2 / \sqrt{1 - c_2^2 - c_2^2 c_3^2}$ to the power half. So this is let us call it as c_4 , in some arbitrary constant we will call it as c_4 . Now this is dz / dx equal to c_4 .

(Refer Slide Time: 18:58)

$z' = c_4$
 $\Rightarrow z = c_4 z + c_5$

$y' = c_3 z' = c_3 c_4 = c_6 \text{ say } \Rightarrow y = c_6 x + c_7$

$F(x, y, z, y', z') = \sqrt{1 + y'^2 + z'^2}$
 $\Rightarrow \frac{\partial F}{\partial y} = 0, F_{y'} = \frac{zy'}{\sqrt{1 + y'^2 + z'^2}}$
 Hence
 $F_z = \frac{d}{dx} F_{z'} = 0$
 $\Rightarrow 0 - \frac{d}{dx} \left(\frac{z z'}{\sqrt{1 + y'^2 + z'^2}} \right) = 0$
 $\Rightarrow \frac{z'}{\sqrt{1 + y'^2 + z'^2}} = c_1$

So z equal to $c_4 x$ plus some constant c_5 .

(Refer Slide Time: 19:12)

From Euler's equations, we have

$$\frac{\partial F}{\partial y} - \frac{d}{dx} F_{y'} = 0, \quad \frac{\partial F}{\partial z} - \frac{d}{dx} F_{z'} = 0$$

$$\Rightarrow \frac{y'}{(1 + y'^2 + z'^2)^{1/2}} = c_1, \quad \dots(1)$$

$$\frac{z'}{(1 + y'^2 + z'^2)^{1/2}} = c_2 \quad \dots(2)$$

and so $y' = c_3 z'$

$$(2) \Rightarrow \frac{z'}{(1 + (1 + c_3^2)z'^2)^{1/2}} = c_2.$$

Hence $z' = \frac{c_2}{(1 - c_2^2 - c_2^2 c_3^2)^{1/2}} = c_4,$

$$\Rightarrow z = c_4 x + c_5. \quad \dots(3)$$

Now $y' = c_3 z' \Rightarrow y = c_6 x + c_7. \quad \dots(4)$

And y' is equal to $c_3 z'$ we have y' equal to $c_3 z'$ here so y' equal to $c_3 z'$ gives us z' is some constant c_4 , so c_3 into c_4 y' is equal to c_6 , c_4 we can so this gives us let us say this is c_6 , so then y is equal to $c_6 x$ plus c_7 . So we get the expressions for y and z in terms of x .

(Refer Slide Time: 19:56)

Thus the extremals are given by (3) and (4).

Since the required extremal has to pass through $P_1(0, 2, 4)$ and $P_2(x_2, y_2, z_2)$, we have

$$y(0) = 2, z(0) = 4, y(x_2) = 3x_2 - 3 \text{ and } z(x_2) = 4x_2 - 4.$$

Now $z = c_4 x + c_5 \Rightarrow c_5 = 4.$

Also, $y(0) = 2$ and $y = c_6 x + c_7 \Rightarrow c_7 = 2.$

Now $z(x_2) = 4x_2 - 4$ and $z = c_4 x + c_5 \Rightarrow c_4 = \frac{4x_2 - 8}{x_2}.$

Example 1: Find the shortest distance of the point $(0, 2, 4)$ to the straight line

$$\frac{x-1}{1} = \frac{y}{3} = \frac{z}{4}.$$

Solution : We have

$$I(y(x), z(x)) = \int_0^{x_2} \sqrt{1 + y'^2 + z'^2} dx,$$

here $F(x, y, z, y', z') = \sqrt{1 + y'^2 + z'^2}$

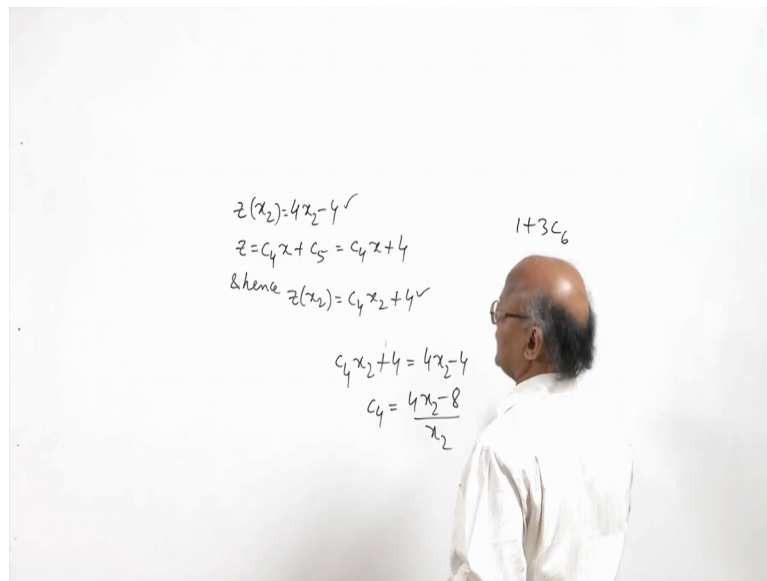

and $\frac{x-1}{1} = \frac{y}{3} = \frac{z}{4} \Rightarrow y = 3x - 3 = \phi(x), z = 4x - 4 = \psi(x), \text{ (say).}$

Now let us find the extremals extremals are given by equation 3 and 4, since the required extremal has to pass through 0 to 4. The line of shortest distance has to pass through the fixed point 0 to 4 and the point variable point x_2, y_2, z_2 we have y at 0 is equal to 2 and because y is a function of x and z is also a function of x . So y at 0 is equal to 2 and z at 0 is equal to 4, this is x_1, y_1, z_1 , y at x_1 is y_1 and z at x_1 is z_1 and similarly y at x_2 is y_2 . So y at x_2 is $3x_2 - 3$ y at x is equal to we have y equal to $3x$ minus 3. So y at x_2 is equal to $3x_2$ minus 3 and z_2 equal to $4x_2$ minus 4. So we get z at x_2 equal to $4x_2$ minus 4.

Now what we have z equal to $c_4 x$ plus c_5 , so in this you put x is equal to 0 x equal to 0 when we put what we get z equal to 4 so c_5 is equal to 4. And y at x equal to 0 is true so what we get is y c_7 is equal to 2. Now z at x_2 is equal to $4x_2$ minus 4 and z is also equal to $c_4 x$ plus c_5 , $c_4 x$ plus c_5 . So c_4 from here what will happen z equal to $c_4 x$ plus c_5 which means z_2 equal to $c_4 x_2$ plus c_5 .

And so what we will get is c_4 equal to c_4 we have already found, c_4 no c_5 we have found c_5 is equal to 4, so z is equal to $c_4 x$ plus 4 and let us this z equal to $c_4 x$ plus c_5 passes through x_2, y_2, z_2 .

(Refer Slide Time: 22:10)

So we get $z \times 2$ equal to $z \times 2$ is equal to 4×2 minus 4 and z equal to $c_4 x$ plus c_5 gives us c_5 is 4 and so and hence $z \times 2$ is equal to $c_4 \times 2$ plus 4, so what do we get from this equation and this equation $c_4 \times 2$ plus 4 is equal to 4×2 minus 4. So we get 4×2 minus 8 c_4 is equal to 4×2 minus 8 divided by x_2 .

(Refer Slide Time: 23:10)

Again, $y(x_2) = 3x_2 - 3$ and $y(x_2) = c_6 x_2 + c_7 \Rightarrow c_6 = \frac{3x_2 - 5}{x_2}$.

Here the following transversality condition has to be satisfied;

$$(F + (\phi' - y')F_{y'} + (\psi' - z')F_{z'})_{x=x_2} = 0$$

$$\left[\sqrt{1 + y'^2 + z'^2} + (3 - y') \frac{y'}{\sqrt{1 + y'^2 + z'^2}} + (4 - z') \frac{z'}{\sqrt{1 + y'^2 + z'^2}} \right]_{x=x_2} = 0$$

$\Rightarrow 1 + 3c_6 + 4c_4 = 0$, as $y' = c_6$ and $z' = c_4$.

12

Thus the extremals are given by (3) and (4).

Since the required extremal has to pass through $P_1(0,2,4)$ and $P_2(x_2, y_2, z_2)$, we have

$$y(0) = 2, z(0) = 4, y(x_2) = 3x_2 - 3 \text{ and } z(x_2) = 4x_2 - 4.$$

$$\text{Now } z = c_4x + c_5 \Rightarrow c_5 = 4.$$

$$\text{Also, } y(0) = 2 \text{ and } y = c_6x + c_7 \Rightarrow c_7 = 2.$$

$$\text{Now } z(x_2) = 4x_2 - 4 \text{ and } z = c_4x + c_5 \Rightarrow c_4 = \frac{4x_2 - 8}{x_2}.$$

Example 1: Find the shortest distance of the point $(0, 2, 4)$ to the straight line

$$\frac{x-1}{1} = \frac{y}{3} = \frac{z}{4}.$$

Solution : We have

$$I(y(x), z(x)) = \int_0^{x_2} \sqrt{1 + y'^2 + z'^2} dx,$$

$$\text{here } F(x, y, z, y', z') = \sqrt{1 + y'^2 + z'^2}$$

$$\text{and } \frac{x-1}{1} = \frac{y}{3} = \frac{z}{4} \Rightarrow y = 3x - 3 = \phi(x), z = 4x - 4 = \psi(x), \text{ (say).}$$

And then $y \times 2$ is equal to 3×2 minus 3 and also $y \times 2$ is equal to $c_6 \times 2$ plus c_7 and we have already found the value of c_7 , c_7 is 2. So we can put here 2 and then solve these two equations for c_6 , c_6 comes out to be 3×2 minus 5 over x_2 . Now since the point x_2, y_2, z_2 lies on the curve the following transversality condition has to be satisfied F plus ϕ dash minus y dash F_y dash plus ψ dash minus z dash F_z dash x equal to x_2 equal to 0, F is given to be under root 1 plus y dash square plus z dash square ϕ dash ϕ_x is equal to $3 \times$ minus 3 ϕ_x is equal to $3 \times$ minus 3, so ϕ dash is equal to 3 and ψ dash is equal to 4.

So let us put these values here, so we get then 3 minus y dash F_y dash is y dash over under root 1 plus y dash square plus z dash square, ψ dash is 4 minus z dash F_z dash is z dash upon under root 1 plus y dash square plus z dash square at x equal to x_2 is 0. Now so you take LCM here under root 1 plus y dash plus z dash square is the LCM and then the

numerator becomes 1 plus y dash square plus z dash square 3 y dash minus y dash square 4 z dash minus z dash square, so y dash square z dash square will cancel and we will get 1 plus 3 y dash plus 4 z dash equal to 0 but y dash is equal to c 6.

(Refer Slide Time: 24:54)

$$\begin{aligned}
 (2) \Rightarrow & \frac{z'}{(1 + (1 + c_3^2)z'^2)^{1/2}} = c_2. \\
 \text{Hence } z' &= \frac{c_2}{(1 - c_2^2 - c_2^2 c_3^2)^{1/2}} = c_4, \\
 \Rightarrow & z = c_4 x + c_5. \quad \dots(3) \\
 \text{Now } y' = c_3 z' &\Rightarrow y = c_6 x + c_7. \quad \dots(4)
 \end{aligned}$$

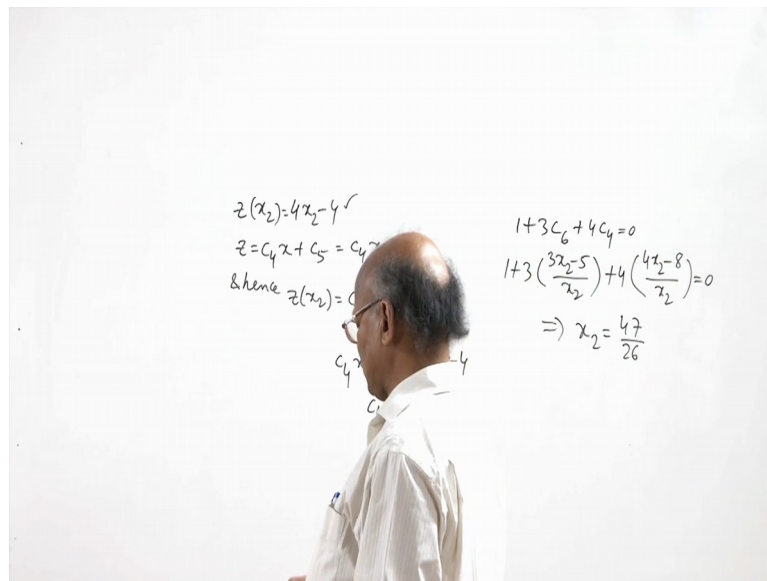

Let us see y dash we have seen to be equal to y dash is equal to c 3 into z dash and c 3 into z dash was equal to c 4, so c 3 into c 4 we defined as c 6, so y dash is c 6 and z dash is c 4.

(Refer Slide Time: 25:07)

$$\begin{aligned}
 \text{Again, } y(x_2) &= 3x_2 - 3 \text{ and } y(x_2) = c_6 x_2 + c_7 \Rightarrow c_6 = \frac{3x_2 - 5}{x_2}. \\
 \text{Here the following transversality condition has to be satisfied;} \\
 (F + (\phi' - y')F_{y'} + (\psi' - z')F_{z'})_{x=x_2} &= 0 \\
 \left[\sqrt{1 + y'^2 + z'^2} + (3 - y') \frac{y'}{\sqrt{1 + y'^2 + z'^2}} + (4 - z') \frac{z'}{\sqrt{1 + y'^2 + z'^2}} \right]_{x=x_2} &= 0 \\
 \Rightarrow 1 + 3c_6 + 4c_4 &= 0, \text{ as } y' = c_6 \text{ and } z' = c_4.
 \end{aligned}$$

So let us replace these values there, so 1 plus 3 y dash means 1 plus 3 c 6 and 4 z dash means 4 c 4, so this is equal to 0 as y dash is c 6, z dash is c 4.

(Refer Slide Time: 25:25)

Now then okay so let us see so we have 1 plus 3 c 6, 1 plus 3 c 6 plus 4 c 4 equal to 0. In this we can put the value of c 6 as 3 x 2 minus 5 over x 2, 3 x 2 minus 5 over x 2 and then we can put the value of c 4 also, so 4 x 2 minus 8 y x 2.

(Refer Slide Time: 26:08)

$$\Rightarrow x_2 = \frac{47}{26}.$$

$$\text{Now } c_4 = \frac{4x_2 - 8}{x_2} \Rightarrow c_4 = -\frac{20}{47}$$

$$\text{and } c_6 = \frac{3x_2 - 5}{x_2} \Rightarrow c_6 = \frac{11}{47}.$$

$$\text{Hence } y = \frac{11}{47}x + 2 \text{ and } z = -\frac{20}{47}x + 4,$$

Thus the extremals are given by (3) and (4).

Since the required extremal has to pass through $P_1(0,2,4)$ and $P_2(x_2, y_2, z_2)$, we have

$$y(0) = 2, z(0) = 4, y(x_2) = 3x_2 - 3 \text{ and } z(x_2) = 4x_2 - 4.$$

$$\text{Now } z = c_4x + c_5 \Rightarrow c_5 = 4.$$

$$\text{Also, } y(0) = 2 \text{ and } y = c_6x + c_7 \Rightarrow c_7 = 2.$$

$$\text{Now } z(x_2) = 4x_2 - 4 \text{ and } z = c_4x + c_5 \Rightarrow c_4 = \frac{4x_2 - 8}{x_2}.$$

And simplify we will get the value of x_2 , x_2 comes out to be $(47 \text{ minus}) 47$ by 26 , so x_2 comes out to be 47 by 26 . Now c_4 , c_4 is equal to c_4 , here is c_4 , c_4 is $4x_2 - 8$ by x_2 . So let us put the value of x_2 here and we get the value of c_4 as $\text{minus } 20$ by 47 , c_6 is $3x_2 - 3$ minus 3 over x_2 , so we get c_6 as 11 by 47 and then we get the value of y equal to y was equal to $c_6x + c_7$. So we get 11 by $47x$ plus 2 and z is equal to $c_4x + c_5$, c_5 is 4 and c_4 we have already found c_4 is $\text{minus } 20$ by 47 , so z is equal to $\text{minus } 20$ by 47 into x plus 44 . So these these are the equations of the line of shortest distance.

(Refer Slide Time: 27:20)

which give the straight line along with the S.D. occurs .

The equations of the line of S.D.

$$\frac{x-0}{47} = \frac{y-2}{11} = \frac{z-4}{-20}.$$

$$\text{The required S.D. } l = \int_0^{x_2} (1 + y'^2 + z'^2)^{1/2} dx$$

$$= \int_0^{47/26} (1 + c_6^2 + c_4^2)^{1/2} dx = \sqrt{\frac{105}{26}}.$$

$$\Rightarrow x_2 = \frac{47}{26}.$$

$$\text{Now } c_4 = \frac{4x_2 - 8}{x_2} \Rightarrow c_4 = -\frac{20}{47}$$

$$\text{and } c_6 = \frac{3x_2 - 5}{x_2} \Rightarrow c_6 = \frac{11}{47}.$$

$$\text{Hence } y = \frac{11}{47}x + 2 \quad \text{and} \quad z = -\frac{20}{47}x + 4,$$

Now so this shortest distance occurs along the straight line equations of the line of shortest distance can be put in this symmetric form these equations which are the equations of the line of shortest distance we can easily put in the symmetric form and the symmetric form is x minus 0 by 47 equal to y minus 2 by 11 equal to z minus 4 by minus 20. Now the required shortest distance is $\int_0^x \sqrt{1 + y'^2 + z'^2} dx$ and $x = 2$ we have found to be $47/26$, so 0 to $47/26$ the value of c_6 is $11/47$, c_4 is minus 20 by 47.

So we can put it them here take the square root and then integrate we get the value square root 105 by 26, so we get the equations of the line of shortest distance and also the required shortest distance, with this I would like to conclude my lecture, thank you very much for your attention.
